higher costs and increases in enrolment. This is evident from a survey by the National Science Foundation. Many of the 86 institutions polled reported that graduate programmes and research had been impaired and the morale of students and staff lowered by the changes in federal funding.

Preliminary results of the survey—Impact of Changes in Federal Science Funding Patterns on Academic Institutions, National Science Foundation, October 15, 1970—which took the form of a questionnaire mailed this spring to 100 institutions granting science doctorates, indicate the total funds for academic research increased by 7·0 per cent between financial years 1968 and 1969, and by 8·5 between 1969 and 1970. But in terms of constant dollars the increase on the two occasions was near to 5 per cent, and during the same period college enrolments rose by 15 per cent.

Table 2. APPROPRIATENESS OF DIVISION OF RESEARCH FUNDS BETWEEN JUNIOR* AND SENIOR† STAFF

Selected science departments, by field	Per cent departments reporting inadequate division of funds for junior staff		
	FY 1968	FY 1969	FY 1970

* Seven years or less from the PhD.
† More than seven years from PhD.
Note: FY 1968 data may not be strictly comparable with FY 1969 and FY 1970 because of a change in the format of the wording on the survey question. Figures rounded to the nearest half per cent.

The most tangible effect of tighter resources has been a deceleration in the addition of faculty members and postdoctorates, whilst in many departments there has been a net reduction in graduate students (see Table 1). Except for chemical engineering and biochemistry, all departments showed smaller growths in their science faculty between 1969 and 1970 than between 1968 and 1969. There have been wide variations in the number of postdoctorates produced in different specialties and institutions, but the data "do not in any event support anecdotal reports of widespread increases in postdoctorates". The largest of recent declines in graduate students has been suffered by mathematics departments, who report a total drop of twenty per cent over the last two years in students supported by federal funds.

The NSF survey has found no evidence to support stories that new doctorates are being starved of their fair share of appropriate research funds. The proportion of departmental heads reporting inadequate division of funds for junior staff has in fact declined since two years ago (see Table 2). Institutions asked to identify the departments most seriously affected by the cutback in federal funds cited their physical science departments most often (44 of the 86 institutions) followed by life science departments (31 institutions) and chemistry departments (19 institutions).

ELECTIONS

The Environment Lobby Wins

by our Washington Correspondent

BOTH Republicans and Democrats are putting the best face on last week's indecisive election results, but it is humbler organizations such as the environmental lobbying groups whose cheers really come from the heart. The environment has been a strong issue in many campaigns and the two national lobbying groups most active on environmental issues, the League of Conservation Voters and Environmental Action, are well pleased with how their candidates fared. Another lobbying interest supported by scientists for arms control and disarmament received less joy from the way the votes fell; of the nine Senate candidates supported by the Council for a Livable World, only four were successful, and the chairman of the Senate Disarmament subcommittee, Senator Albert Gore of Tennessee, was defeated.

The League of Conservation Voters reports that sixteen of the twenty candidates it endorsed were re-elected. The organization is particularly pleased with the defeat of Governor Samuelson of Idaho, whose policies on environment protection are said to have given excessive favour to industrial interests. The League also rejoices over the defeat in a Maryland Democratic primary of Representative George Fallon, a 13-term Congressman who had been chairman of the House Public Works Committee and was one of the originators of the Highway Trust Fund. A satisfactory score is also recorded by Environmental Action. Seven of the twelve Congressmen it singled out for bad voting records on environmental matters went down to defeat and six of the "dirty dozen" were replaced by candidates thought to be favourable to the group's aims.

The two groups are both of recent standing. Environmental Action is an outgrowth of the activities of

last April 22, designated Earth Day, and the League of Conservation Voters, the political arm of Friends of the Earth, has been in action for slightly over a year. The league, which contributed a total of $45,000 to its candidates, was founded by Marion Edey, a former legislative assistant to Representative Wolff of New York. Its interests are no narrower than "preservation of the ecosystem" but the particular issues it is now pursuing are the curtailment of the supersonic transport and the "development of alternative power sources" (alternative, in particular, to nuclear power). Environmental Action has chosen as its three main issues for the immediate future clean air legislation, with particular respect to automobile exhaust standards, the SST, and occupational health and safety. A member of the group said this week it was hopeful the new Congress would be "more environmentally conscious" than the last.

The new Congress is less decidedly favourable to advocates of arms control although Thomas A. Halsted, director of the Council for a Livable World, describes the net effects of the changes in the Senate as fairly neutral. The council, founded in 1962 to halt the arms race and eliminate war, operates by arranging seminars for Senators on matters such as the anti-ballistic missile system and by supporting candidates of its choice in Senatorial elections. In last week's elections five of the council's nine favoured candidates were defeated and one of them, Senator Vance Hartke of Indiana, scraped in only after a recount. But the council, which raised some $300,000 in support of its candidates, is sanguine about the losses. "In the past our batting average has been better, but we took a few long shots", Halsted said this week. Several candidates were prime targets of the White House campaign, including in particular Senator Gore, whose defeat is the most serious loss. A member of Senator Fulbright's Foreign Relations Committee and chairman of its Disarmament Subcommittee, Gore has been one of the chief opponents of the ABM system in the Senate debates this year and last. His successor as chairman of the Disarmament Subcommittee has yet to be announced.

POLLUTION

Lawyer for Environment

by our Washington Correspondent

An assistant attorney-general of the Justice Department, Mr William D. Ruckelshaus, is to be the first head of the Environmental Protection Agency, President Nixon announced last week. The agency, which will become operative on December 2, will have the care of 5,700 employees and an estimated budget of $1,400 million. The agency will be entrusted with the task of enforcing present and future legislation against all forms of pollution. It draws together some fifteen programmes and bureaux at present scattered round various departments, of which the most important are the Federal Water Quality Administration, now in the Department of the Interior, and the National Air Pollution Control Administration and the Bureau of Solid Wastes, now part of the Department of Health, Education and Welfare. The agency will also inherit the pesticide control programmes operated by the Department of Agriculture and some part of the AEC's responsibility for control of radiation.

Like Mr Russell Train, the chairman of the Council on Environmental Quality, Mr Ruckelshaus's background is that of a government lawyer. Whereas Mr Train specialized in tax law, Mr Ruckelshaus's interests have lain appropriately in the control of pollution. After a law degree at Harvard, he became assistant attorney-general with the Indiana State Health Department where he prosecuted violators of water pollution and other health laws. In 1963 he drafted Indiana's air pollution control law and from 1966 to 1969 he was majority leader in the Indiana State legislature. Two years ago he was the Republican candidate for Senator but was defeated by Senator Birch Bayh. Mr Ruckelshaus becomes head of the Environmental Protection Agency at the age of 38.

Ecology Rampant

"We are frequently told that Lake Erie is dead—when the total fish catch is rising, not falling. Lake Washington was on its way to becoming as dead as Erie, so it was said, and its reversal is viewed as a great triumph. And it surely was a triumph of political organization. But the polluted lake was great for salmon fishing, and now the water is so pure it has difficulty supporting the salmon. Air pollution is always unpleasant and a lengthy inversion can undoubtedly be dangerous—but automotive emissions are controllable and I cannot help but wonder whether this problem is trivial compared to the carnage we suffer on the highways to which we seem to have become inured, with intoxicated youth the most frequent offenders. Bumper stickers decry DDT across the land demanding its total ban rather than regulated usage—but the next generation of pesticides has killed or blinded dozens of people this year—and no American is known to have been injured by DDT. . . . I have no wish to minimize the seriousness of our environmental problems. They are huge and in need of large-scale, urgent attention. But is it not time to stop frightening the American people and instead demand the very large systematic programme necessary to acquire the data which would permit quantitative evaluation of the risks versus the benefits in all those areas where man's intervention has already or yet may degrade the environment? We need to know far more about pesticide usage, food additives, drugs, industrial practices, radiation hazards, atmospheric phenomena and the alleged fragility of ecosystems than we do today if we are to make sound judgments and establish public policy. What puzzles me is the apathy of college students toward our vast arsenal of nuclear weapons—the infrequency of demands for a massive systematic approach to the attainment of a stable, enduring, just peace. Or why our students do not become angry about the desperate state of our rural poor." From a speech given by Dr Philip Handler, president of the National Academy of Sciences, at the Sesquicentennial of the University of Indiana, October 13.

NEWS AND VIEWS

Are Ribosomes Artefacts?

ALTHOUGH it has been known almost since the very beginnings of molecular biology that the functional unit which translates messengers is the 70S ribosome, the question of whether 70S ribosomes exist free in the cell remains as perplexing as ever. Initiation of protein synthesis requires formation of a complex between messenger RNA and a 30S ribosomal subunit; the 50S subunit only subsequently joins the complex to create the 70S ribosome which then sets off to translate the messenger. Because ribosomal subunits undergo many rounds of protein synthesis, a ribosome must dissociate into its two subunits after completing synthesis of one protein but before starting synthesis of another. But just when ribosomal subunits exchange their partners is one of the most vexed issues of protein synthesis.

When *Escherichia coli* cells are lysed in the presence of sodium ions, only polysomes and free subunits are found; this suggests that ribosomal subunits dissociate at termination of protein synthesis, not to reassociate until initiation of the next protein, so that cells contain virtually no 70S ribosomes free of messengers. But when potassium ions are used instead of sodium, free 70S ribosomes are present as well as the polysomes and subunits. This would result if ribosomes are released from messengers into a pool of free 70S ribosomes and only subsequently dissociate to maintain the pools of 30S and 50S subunits.

Deciding which of these distributions represents the situation *in vivo* and which is an artefact is complicated by the finding that ribosomes do not dissociate spontaneously into subunits (whether at or after protein termination) but seem to do so only when a protein factor complexes with the 30S subunit. This dissociation factor is itself released from the 30S subunit on initiation of the next round of protein synthesis. On page 534 of the last issue of *Nature*, Kaempfer has exacerbated the issue by proposing that the ribosome subunit cycle is yet more complicated.

The need for cyclic dissociation and reassociation of ribosomal subunits in an *in vitro* system has already been shown by dilution experiments. In principle, an extract of polysomes derived from bacteria grown in heavy isotopes is transferred into an excess of polysomes from bacteria grown in normal medium. The source of the ribosomes can be identified by their sedimentation behaviour. After the dilution, their density distribution shows a progressive replacement of heavy ribosomes by hybrids which contain one heavy subunit and one light subunit. This implies that dissociation and reassociation must be taking place.

Further details of the cycle have now been found by changing the conditions of the dilution. When the reassociation of ribosomal subunits but not the completion of nascent polypeptide chains is prevented, ribosomes should accumulate in the extract in whatever form they are released from messengers. This proved to be subunits and not 70S agglomerates.

But using sub-optimum conditions for protein synthesis (limiting initiation by a low availability of free subunits), free 70S ribosomes accumulate in the extract. These could represent ribosomes which have run off polysomes but cannot, for some reason, dissociate into subunits as usual. If this were so, placing an extract of heavy polysomes in an excess of light polysomes should produce only all heavy or all light ribosomes. But, instead, all the 70S ribosomes proved to be hybrid; this indicates that they must derive from the association of free subunits after release from messengers. Their behaviour shows some significant differences compared with ribosomes derived by breakdown of polysomes; they sediment a little more slowly and can be dissociated into subunits by ribonuclease. And they dissociate more easily in the presence of sodium ions.

What role do these ribosomes play in the translation cycle? Kaempfer suggests that free 70S ribosomes do not exist during rapid protein synthesis; ribosomes are released from messengers as subunits and reassociate only at the next initiation. But when protein synthesis slows down, the free subunits accumulate and then associate to yield 70S ribosomes. These ribosomes comprise a dead end pool and do not participate in protein synthesis, which takes place by a preferential recycling of a different set of subunits. When the rate of protein synthesis increases again, the storage pool of inactive ribosomes is mobilized to return to subunits, perhaps by mediation of a protein factor.

How does this cycle fit in with what is known about the action of the dissociation factor? This is difficult to decide because these ribosomes and subunits have

not been assayed for the presence or absence of the factor. Indeed, a major weakness in the theories of those workers who indulge in arguments about which ionic conditions represent the true distribution of ribosomes and which an artefact, is their apparent reluctance to examine these ribosomes for the presence or absence of dissociation factor. The more is discovered about protein synthesis, the more it seems that no aspect is so negligible as to be left to the vagaries of spontaneous action. Specific protein factors mediate each step of protein synthesis, and it is unlikely indeed that the association and dissociation of ribosomal subunits is any exception. It is doubtful whether the significance of free 70S ribosomes can be resolved until the dissociation factor has been properly characterized and its participation in the ribosome subunit cycle completely assayed.

TUMOUR IMMUNOLOGY

Foetal Antigens and Tumour Cells

from our Cell Biology Correspondent

CELL surface chemistry has become one of the great rallying cries of cancer research. Currently the changes in the cell surface which accompany the transformation of cultivated cells by tumour viruses and which can be detected by agglutination tests with plant agglutinins are exciting great interest (see *Nature*, **228**, 502, 512; 1970). For the exposure of the agglutinin sites or some concomitant change in the cell surface may well play an integral part in the establishment and/or maintenance of neoplastic transformation. And, of course, those changes which result in new antigenicities play a crucial part in the interaction between tumour cells and their hosts.

One of the most intriguing discoveries in this field, made by Gold and Friedman in 1953, is that tumour antigens from human adenocarcinoma cells cross-react with foetal antigens found on gut, liver and pancreatic cells only during the second to sixth months of foetal life. These observations, and similar observations made subsequently by other groups, which indicate that transformation results in the exposure and/or synthesis anew of foetal antigens, have now found an interesting parallel *in vitro*. Baranska, Koldovsky and Koprowski (*Proc. US Nat. Acad. Sci.*, **67**, 193; 1970) have obtained a serum from guinea-pigs immunized with unfertilized mouse eggs which, in the presence of complement, is cytotoxic for allogeneic and syngeneic mouse eggs. This serum is also toxic for two lines of mouse cells transformed by SV40, but it is not toxic for the corresponding untransformed cells. Neither is it toxic for rat eggs, a variety of tissues of adult mice and the cells of tumours induced in mice by methylcholanthrene. Baranska *et al.* clinch their argument that the SV40 transformed cells carry an antigen present on unfertilized eggs by showing that after the serum is absorbed with SV40-transformed cells it is no longer toxic for mouse eggs. The chief question now, of course, is whether this antigen is present in a cryptic state in all mouse cells and is unmasked by transformation or whether transformation derepresses the synthesis of a foetal antigen.

Huebner and nine co-workers (*ibid.*, 366) have also detected an antigen in tissues of foetal mice which is not present in young adult mice but reappears with increasing age. They found the group-specific antigen of the murine leukaemia and sarcoma viruses in embryos of all the strains of mice tested even though the mice, in adult life, may be free of infectious virus and subject to only a low incidence of leukaemia. Perhaps the most interesting observations are those relating to wild mice trapped in various parts of the United States. Apparently most wild mice have the group-specific antigen at some stage in their foetal life but less than 2 per cent of young adult animals have the antigen in their spleen or liver cells. In older mice, however, especially those bearing chemically induced sarcomas, the antigen can be detected. On the face of things it seems that most mice carry the genes which specify the group-specific antigens of the murine leukaemia and sarcoma viruses. There is a precedent for the occurrence of the genes of RNA tumour viruses in apparently uninfected animals; some strains of chickens carry the group-specific antigens of the avian RNA tumour viruses and the genes for these antigens are inherited as a dominant trait in a simple Mendelian fashion. Needless to say, Huebner *et al.* interpret all these observations in terms of their oncogene hypothesis; they believe that the genes for the RNA tumour viruses are part of the genome of animals and that these genes may have a role in normal embryogenesis as well as specifying the viral genomes and acting as determinants of cancer.

Happily, even tumour virology has its lighter sides, and the headline writers of the popular dailies might learn a lesson or two from the current issue of the *Proceedings* (*ibid.*, 37). "DNA and Gene Therapy" is after all by any standards a riveting headline even if what follows, "Uncoating of Polyoma Pseudovirus in Mouse Embryo Cells", belies it. All Osterman and his colleagues have shown is that polyoma pseudovirions, pieces of host DNA enclosed in polyoma virus capsids, are uncoated in mouse embryo cells. What they so pretentiously herald, apart from a series of their own articles, is the dawn of "the use of DNA for gene therapy in man" and what they are well on the way to discovering is the road to ridicule if not damnation.

TRANSFER RNA

Looking for Sites

from our Molecular Biology Correspondent

TRANSFER RNA is a molecule which embodies almost all the characteristics of an enzyme, with, moreover, the ability to engage in a great variety of recognition and binding processes. The delineation of its active sites has occupied many laboratories. One facet of its action that has received relatively little attention so far is its interaction with protein synthesis factors. Chen and Ofengand (*Biochem. Biophys. Res. Commun.*, **41**, 190; 1970) now report the results of the first attempt to identify the site of the interaction of yeast phenylalanyl-tRNA with the factor T_u and its associated GTP, which constitutes the first step in the peptide synthesis cycle on the ribosome. It is established that the reaction requires that the bound amino-acid on the tRNA be intact, and also apparently that the RNA be in its native conformation. Chen and Ofengand have found that after oxidative cleavage of the ribose ring with periodate, followed by reduction of the

product to a diol, by means of borohydride, the resulting molecule can still be charged with its amino-acid. The modified phenylalanyl-tRNA was unable, however, to attach to the T_u-GTP complex, neither could any binding to ribosomes and poly U be detected; that is to say, recognition of the T_u-independent peptidyl-tRNA site (P-site) on the ribosome was lost. It seems then that the intact 3′-terminus is a requirement for the T_u-GTP interaction, which is a function common to all tRNAs, but not for the aminoacylation reaction.

The exploration of essential and inessential parts of the chain by excision of nucleotides has been pursued especially by groups in Russia and in Japan. The latest study by Chuguev, Axelrod and Bayev (*ibid.*, 108) deals with yeast valine tRNA, which, like a number of other species, can be split in two by nuclease hydrolysis of a single bond in the central loop. The halves can be separated and recombined with retention of activity towards aminoacyl synthetase, as well as the enzyme which attaches the terminal CpCpA sequence, when this has been removed. By the use of alkaline phosphatase and periodate oxidation, Chuguev *et al.* have progressively nibbled away nucleotides at the 3′-end of the 5′-half of the chain. Five residues, including the pseudouracil, were eliminated in this way, and when the resulting fragment was recombined with the intact 3′-half substantial activity in respect both of amino-acid uptake and the CpCpA joining reaction was found to have survived. Thus sites for two activities do not involve the central loop directly, nor is this required to maintain a conformation which is active in these respects.

Thiebe and Zachau (*Biochim. Biophys. Acta*, **217**, 294; 1970) have tested the acceptor activity of yeast phenylalanine tRNA after chemical modification. The RNA contains a unique base of unknown structure, Y, next to the anticodon. It is labile to acid, and this forms the basis of its chemical excision from the chain. The product has acceptor activity in the endogenous system, but requires a higher magnesium concentration to be charged at an appreciable rate. Moreover, towards *E. coli* synthetase it is completely inactive, by contrast with the native yeast phenylalanine tRNA. The indications are that the removal of the Y-base brings about a conformational destabilization, an inference which is supported by a comparison of the optical properties of the native and modified species.

It may be noted that Cheng and McAllister (*ibid.*, 217) give evidence of specific protection of two ribosomal proteins in *E. coli* towards iodoacetamide by bound aminoacyl-tRNA and poly U. This raises the question of recognition sites on the tRNA for ribosomal proteins, which perhaps serve to register it on the ribosome. Sho, Daneo-Moore and Shockman (*Biochemistry*, **9**, 3372; 1970) have also reported the existence of a ribosomal protein, present in the CsCl-treated core of the 50S particle, which, when isolated, is found to inhibit the poly U directed binding of phenylalanyl-tRNA to the ribosome.

TUMOUR VIROLOGY

The Paris Fashions

from a Correspondent

THE success of the Second Lepetit International Colloquium, held in Paris from November 6–8, must have established these annual meetings, sponsored by the Italian pharmaceutical company Lepetit, as a regular feature of the scientific calendar. And these meetings seem, especially to those who were invited, an enlightened way of using up advertising budgets. The subject discussed this year—the biology of tumour viruses—has had an almost continuous airing at more than half a dozen international meetings held since May; the fact that, in spite of this, new and exciting results were reported in Paris speaks much for the extraordinary progress that is being made and Lepetit's good luck.

The meeting started badly with the first two sessions dominated by poor speakers presenting dull data. Only Basilico (New York University), who reported preliminary results which suggest that transforming wild-type polyoma genomes may be rescued from mouse–hamster hybrid cells by superinfection with the ts-a mutant of polyoma virus, and Darnell (Columbia University), who reported that some of the RNA molecules in the nuclei of SV-3T3 cells contain cellular and SV40 sequences, relieved the tedium.

It was the second day's proceedings, devoted to the RNA tumour viruses, which made the trip to Paris worthwhile. Schäfer (Tübingen) reported the separation of two group-specific antigens in feline leukaemia virus and a third interspecific group antigen which is also present in mouse, rat and hamster sarcoma and leukaemia viruses and perhaps in bovine leukotic cells, human breast cancer and leukaemia cells in culture. This suggests, of course, that these human cancers might be caused by a virus of the mammalian leukaemia and sarcoma virus assemblage. Aaronson (NIH) reported that murine sarcoma virus can transform BALB/c 3T3 cells without the help of a murine leukaemia virus. Interestingly enough, although the transformed cells do not liberate murine sarcoma viruses these can be rescued by superinfection with a leukaemia virus but the transformed cells do not contain detectable group specific antigens of the sarcoma virus.

These two speakers were followed by Hanafusa (New York Public Health Research Institute). His work on Rous sarcoma virus is legendary and he did not disappoint. He first reported the identification of the transmissible factor which renders COFAL negative cells effectively COFAL positive as an avian leukaemia virus of subgroup O. Apparently when Rous sarcoma virus of this subgroup infects COFAL positive cells it rescues avian leukaemia virus which, integrated into the host chromosome and inherited in a Mendelian fashion, seems to be the COFAL factor. He went on to provide the most direct evidence yet available that the RNA and DNA dependent polymerase activities in RNA tumour viruses play a part in transformation. Certain cells transformed by Rous sarcoma virus liberate progeny virus that is uninfectious and cannot transform even when it is fused into susceptible cells with inactivated Sendai virus. RSVα(O), as this progeny virus is called, lacks both polymerase activities. When cells producing RSVα(O) are superinfected with an avian leukaemia virus the progeny include sarcoma virus particles which can transform cells. But the cells transformed by this virus once again produce sarcoma virus progeny which are absolute defectives for infectivity and transformation. These data suggest that the superinfecting leukaemia virus provides RSVα(O) with the two polymerase activities;

the virus particles can then transform cells but, because they cannot specify the polymerases, the progeny from the transformed cells are defective. Clearly if this interpretation is correct the RNA and DNA dependent polymerase activities are essential for the establishment of transformation but not its maintenance. The temperature sensitive Rous sarcoma viruses isolated by Martin (Berkeley), which can transform cells at 36° C but not at 41° C, on the other hand prove that the continuous production of some other viral gene product is required for maintenance of transformation.

Duesberg (Berkeley) has shown that the small pieces of DNA made by the polymerase activities in Rous sarcoma virus include at least 90 per cent of the sequences in the viral DNA. He also reported that the 60–70S RNA in avian sarcoma viruses can, after denaturation, be resolved into two classes of subunits, the *a* and *b* subunits. The RNA of the avian leukaemia viruses lack the *a* subunits as does a non-transforming mutant of Rous sarcoma virus described by Vogt (Washington). He suggested the *a* subunit of the viral RNA genomes may contain the genes required for the transformation of chick embryo fibroblasts. Temin (Wisconsin) described his protovirus hypothesis; he suggests that the two polymerase activities may be present in somatic cells and might, together with RNA molecules, have a role in the intercellular transfer of genetic information and gene amplification in such processes as embryogenesis, antibody production and memory.

Perhaps the highlight of the meeting was yet to come. Spiegelman (Columbia), Gallo (NIH) and Green (St Louis) all reported detecting either RNA or RNA · DNA hybrid dependent polymerase activities in extracts of human leukaemic white blood cells. Spiegelman has now detected this activity in nine out of nine cases but never in controls, and after chemotherapy the white blood cell count of these patients returns to near normal and the activities can no longer be detected. His group have solubilized the hybrid dependent polymerase activity present in the leukaemic cells of one patient and find, as with the cruder extracts from the other patients, it prefers poly dT · poly rA to any other template tested to date. In an impassioned plea for cooperation rather than competition Spiegelman said "the prize here is to help sick kids get over leukaemia" and not, to paraphrase his words, a weekend in Stockholm.

The detection of polymerase activities in leukaemic cells obviously suggests that human leukaemia viruses may exist, but, as Todaro (NIH) noted, these activities are also present in visna virus and primate syncytium forming viruses. They are not specific to the RNA tumour viruses and that should warn against over hasty conclusions.

The final day was devoted to mutants of the DNA and RNA tumour viruses and to changes in the cell surface of transformed cells which result in the exposure of agglutinin receptors. Burger (Princeton) described the experiments he reported in *Nature* last week (**228**, 512; 1970). The only cloud on that horizon is that there is a surprising lack of information about these sites on cells transformed by RNA tumour viruses. If the exposure of the sites is crucial for maintaining the transformed cell phenotype they should be exposed on cells transformed by the RNA viruses. It is high time someone looked in detail at such cells.

POLLUTION

Danger in the Air

THE relaxing of smoke control orders in Britain this winter will provide some interesting, if not entirely welcome, work for the staff of the Medical Research Council's Air Pollution Research Unit. The shortage of smokeless fuel will give them the opportunity to discover whether the health of bronchitic patients declines, after a steady improvement which has been evident since the implementation of the Clean Air Act of 1955.

One of the epidemiological studies which visitors inspected when the unit put its work on show earlier this week began in the winter of 1955–6. A group of patients in London, who were susceptible to bronchitis, began to record their daily state of health. At this time bronchitis clearly worsened rapidly when the concentrations of smoke and sulphur dioxide in the air increased suddenly. The situation was much the same in the winter of 1959–60, but five years later there was far less correlation of illness with changes in air pollution. Even when the concentrations of smoke and sulphur dioxide in the air reached 1,000 μl./m^3 patients did not always record a worsening of their conditions. And by 1969–70 there was very little change in the health of patients when the amount of atmospheric pollution increased.

This apparent decline in sensitivity to air pollution during fifteen years could well be a consequence of the drastic reduction in the concentrations of smoke and sulphur dioxide in the London air, although Mr R. E. Waller, the unit's epidemiologist, points out that improved methods of treatment could have been partly responsible for the improvement in the health of the patients. In any case, he says, it is too early to say whether the acute effects of air pollution in London have been eliminated. The signs are encouraging, however.

The epidemiology of lung cancer is another of Mr Waller's interests, but it is becoming increasingly apparent that cigarette smoking is a far more significant cause of this disease than air pollution. Investigations have started recently into the effects of polluted air and smoking on the function of the lungs. The basis for this work is the maximum rate at which a subject can exhale air—the peak flow rate—which is a measure of the state of health of the lungs. The peak flow rate is less for lungs which are infected, or diseased in any other way, than for a healthy set of lungs. Members of the staff of the unit have been measuring their peak flow rate daily for five years and have found a steady increase in the value recorded.

Smaller scale investigations in progress include chemical analysis of various pollutants, including asbestos, which is no longer confined to industrial atmospheres. Various constituents have been identified, including paraffinic hydrocarbons and 3 : 4-benzpyrene, but their biological significance has yet to be assessed. Work also continues on bacteriological aspects of air pollution. Particulate pollutants from London air turned out to stimulate the growth of *Haemophilus influenzae*, which is recovered from patients with chronic bronchitis. The pollutants also inhibited the growth of various bacteria found in the respiratory tract. So far it seems that the best inhibitors are obtained by evaporating aqueous filtrates of the pollutants, while the best stimulators come from the fractions extracted with

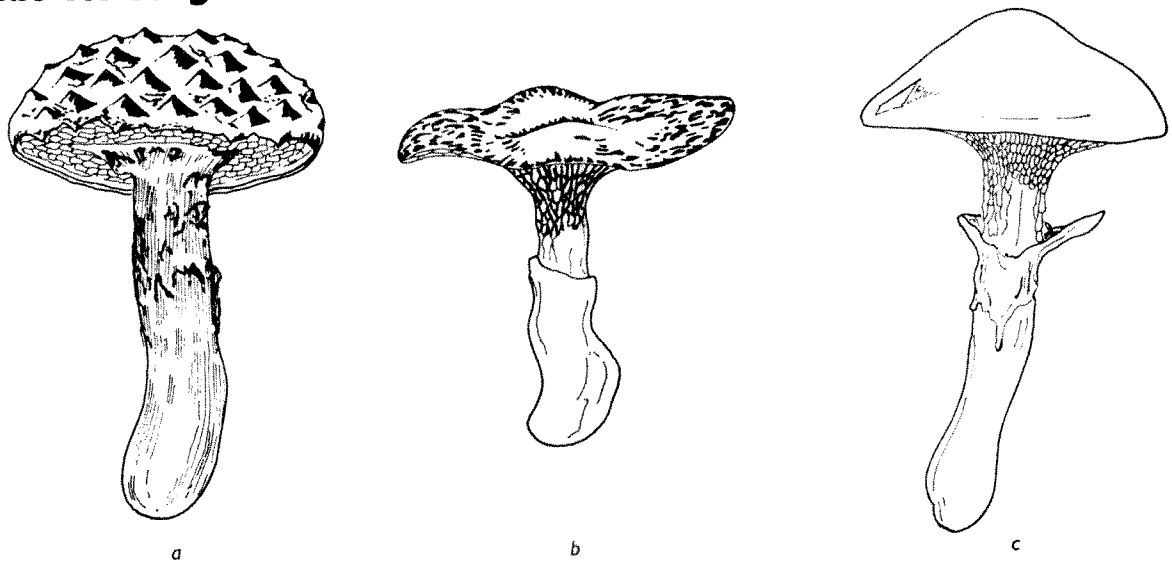
organic solvents. The precise mechanism will no doubt be worked out later. They do not look for sudden breakthroughs at the Air Pollution Research Unit.

INTERSTELLAR DUST

Ultraviolet Observations a Problem

by our Astronomy Correspondent

A NEW observation of Barnard's Loop Nebula in the constellation Orion, reported in *Science*, has turned up another piece in the jigsaw which one day will reveal the nature of the interstellar dust (**170**, 527; 1970). The new data refer to the far ultraviolet part of the spectrum, which, according to recent observations of stars that are partially obscured by dust clouds, is removed by the dust to at least the same extent as the near ultraviolet, if not more. Either absorption or scattering of the starlight by the dust must be responsible. In the near ultraviolet, the more accessible part of the spectrum, scattering seems to be important. Barnard's Loop Nebula has been detected at these wavelengths, by an ultraviolet camera carried on a Gemini flight in 1966, presumably because the dust in the nebula is scattering ultraviolet radiation from the hot stars in Orion toward the Earth. It might be expected that the nebula could be detected in the far ultraviolet by the same scattering process, but rather surprisingly this has turned out not to be the case.



In the *Science* article, three photographs of Orion which ought to have shown Barnard's Loop Nebula are discussed by Richard C. Henry and by George R. Carruthers, who first reported observations of interstellar molecular hydrogen. Using a special camera developed at the Naval Research Laboratory and to be carried on one of the later Apollo missions, assuming there are no more cancellations, photographs of Orion and the Monoceros constellation were obtained in the wavelength band 2100–1230 Å in the far ultraviolet. This stops short of the Lyman α emission at 1216 Å which could easily have fogged the photographs. Although a conservative estimate makes their camera at least as sensitive as that which recorded Barnard's Loop Nebula in the near ultraviolet, Henry and Carruthers found no sign of the nebula on their photographs.

What this implies about the material of the nebula is by no means certain, but at least it shows that the far ultraviolet is not being scattered toward the Earth like the longer wavelengths. There are no strong reasons for supposing that the stellar radiation falls off toward the far ultraviolet to account for the non-detection of the nebula at 2100–1230 Å. Either absorption by the dust is coming into play at these wavelengths, or the radiation is not being scattered through sufficiently large angles for significant amounts of it to be directed at the Earth. Either way Henry and Carruthers see their data as relevant to the question of the nature of the dust particles although none of the models which have been put forward so far seem to fit their observations at a first glance.

Altogether the camera took thirty photographs during a rocket flight last year, each with a seven second exposure made possible by a combined electronic and photographic system. The image is formed on a photocathode at the focus of the collecting mirror, and a solenoid surrounding the optics directs the photoelectrons onto an emulsion behind the mirror. In this system each electron has enough energy to blacken a grain in the emulsion, making possible the large return of photographs from a short flight. Nobody was surprised that one of the brightest optical stars in the sky, Betelgeuse, should be missing from the ultraviolet photographs which otherwise show the Orion constellation distinctly. Cool supergiants would not be expected to register at those wavelengths.

MYCOLOGY

Guide for Fungus Collectors

a *b* *c*

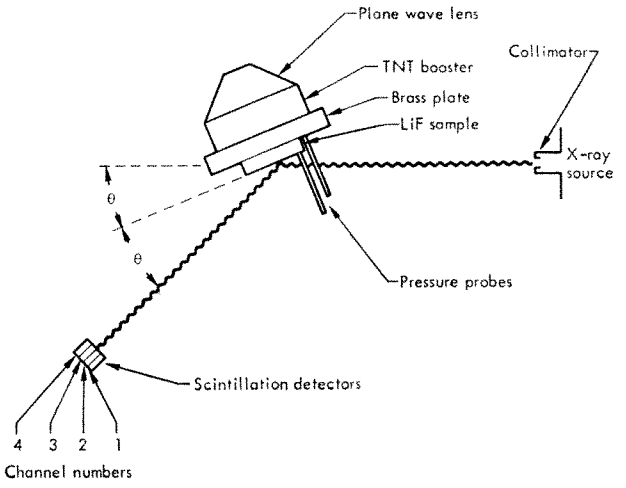
Strobilomyces floccopus (*a*), *Boletinus cavipes* (*b*) and *Suillus grevillea* (*c*) are three of the fungi described in the latest volume of the *British Fungus Flora* (R. Watling, *Boletaceae: Gomphidiaceae: Paxillaceae*, HMSO, 1970, £2 10s). Many a mycologist will doubtless be grateful to take up this book when returning from a profitable fungus foray.

VARIABLE STARS

Absorption in the Infrared

by our Cosmology Correspondent

A CORRELATION between the infrared absorption band of H_2O at 1·9 μm and the microwave emission of the same molecule in long-period Mira variables suggests details of the mass loss mechanism operating in these stars.



J. A. Frogel reports that absorption features characteristic of water vapour have been detected in the spectra of seventeen Mira variables, and that the variation of the intensity of the 1·9 μm band is inversely correlated with that of the radio emission of this molecule at 1·35 cm and with the optical luminosity variations (*Astrophys. J.*, **162**, L5; 1970). The infrared measurements have been carried out using a 0·5 m Ebert–Fastie spectrometer; Frogel used a comparison between the 1·9 μm band and the 2·25 μm band to determine the variation at 1·9 μm, because at 2·25 μm there is neither stellar absorption nor terrestrial atmospheric absorption, so that measurements at this wavelength provide a good indication of the variation of the total light curve of the star. Relative to the 2·25 μm feature, the 1·9 μm absorption rises to a maximum just before the minimum of the light curve, after which it decreases rapidly to a minimum value which is maintained for roughly one-fifth of the optical period before a slow rise to the next maximum. The available data at microwave frequencies suggest that the emission at 1·35 cm is positively correlated with the optical variations (compare P. Schwartz and A. Barrett, *Astrophys. J.*, **159**, L123; 1970).

The model which Frogel proposes to explain this behaviour depends in detail on the way in which mass loss occurs from these stars. He suggests that around the maximum of the optical intensity so much material is expelled above the photosphere that the water which forms (independently of pressure below 2,500 K) increases in quantity so rapidly that at first this gain outweighs the decrease in absorptivity resulting from its falling temperature. Once the star is well passed maximum intensity, the rapid cooling of the water vapour and lack of any new material soon produce a decrease in the observed absorption to a minimum. As the cycle repeats, the water vapour surrounding the star remains associated as H_2O, and just before maximum luminosity conditions are suitable for the pumping required to produce the observed microwave radiation by maser action. This model is very susceptible to observational tests, because it intimately relates the microwave and infrared behaviour of the sources. Conditions suitable for the formation of H_2O might also be expected to be close to those needed for production of OH, so that these three classes of emission or absorption objects could well be members of one basic family.

SOLIDS

X-rays and Shock Waves

ALTHOUGH X-ray diffraction has been used to study the structure of solids since near the beginning of the twentieth century, it has usually been a technique carried out over fairly long periods of time with crystals which were not subject to sudden large distortions. The desire to look at solids undergoing rapid deformations has increased with the ever growing interest in the interaction of, for example, phonons and laser radiation with matter. The problems of looking at phenomena in solids which last only a few tens of nanoseconds are, however, great and are associated chiefly with the switching of a sufficiently short and intense pulse of X-rays at the correct time.

Experimental arrangement for X-ray diffraction study of LiF under shock compression.

Johnson *et al.* report from the Lawrence Radiation Laboratory of the University of California (*Physical Review Letters*, **25**, 1099; 1970) that they have devised an experimental system which has broadly overcome these problems. They do not describe their pulsed X-ray generator in detail, but the apparatus with which they have managed to observe X-ray diffraction from a crystal of lithium fluoride under shock wave compression is illustrated here.

The transit time for the shock wave from a small TNT charge was measured with two pressure probes which defined the time of entry and exit of the shock wave and made it possible to calculate the shock pressure. Because most of the diffracted X-rays come from very close to the surface of the crystal, it is important to switch on the X-rays about 30 ns before the estimated time of breakout of the shock wave so that the compressed state can be properly observed. If X-rays were truly diffracted from the compressed state of the crystal, the signals from channel 2 would be expected to increase by a factor of about three and those from channel 4 to decrease by about the same amount. In the best experimental run, the output from channel 2 was found to be up by a factor of about 2·7 and that from channel 4 down by a factor of about 0·7. The centre of each scintillator is about 0·2 cm from its neighbour and the resolution of the apparatus is clearly not very high, but if it is assumed that a diffraction line shift from channel 4 to channel 2 has taken place, the corresponding $\Delta 2\theta$ ($\sim$2·6°) is quite close to that expected for an isotropic applied pressure of the size calculated from the shock transit time ($\sim$130 kbar). In other words, the unit cell of the lattice is being compressed from a cube into a smaller cube rather than into a rectangular box of square cross-section, as might be intuitively expected when a plane shock wave is applied to a crystal. As well as establishing a technique which will doubtless be improved in the near future, this work seems to have thrown up some interesting side issues.

Molecular Biology in the Year 2000

by
FRANCIS CRICK
MRC Laboratory of Molecular Biology,
Hills Road,
Cambridge CB2 2QH

By the year 2000 most of the problems now facing us in molecular biology will probably have been solved, but new and unexpected developments are likely to make the subject just as exciting then as it is today. This was the theme of Dr Crick's contribution to a conference held in October 1969 to help celebrate *Nature*'s centenary. This article is based on his talk.

I WANT to consider the future of molecular biology and, to a lesser extent, of cell biology*. I do not consider here applied biology nor the social implications of biological research, not because these are unimportant subjects but simply to keep the discussion within reasonable limits.

We must first consider the length of time over which it is useful to make forecasts. It is often not difficult to make short range forecasts for periods up to, say, five or ten years ahead. Molecular biologists have acquired some experience in predictions of this sort in molecular biology. During the past twenty years such forecasts have usually turned out to be correct. What has been rather variable, however, is the estimate of the precise time involved. An error in time of a factor of two is not at all uncommon. Thus at a certain stage it was possible to say, with a fair degree of confidence, that the genetic code would some day be discovered. If one made an estimate that this would happen within, say, five years, then experience has shown that the actual time might be as short as two or three years or as long as eight or ten.

In case you should think that my own judgment is peculiarly erratic, I should say that other people's judgments seem to be little better! There is an amusing example concerning the structure of proteins. After Perutz and Kendrew had discovered the structure of haemoglobin and myoglobin, Sir Lawrence Bragg forecast that it would be another ten years before a further protein was worked out to this sort of resolution. In fact, the next protein whose structure was solved was lysozyme. It took only about five years instead of the ten years expected and ironically enough it was done by David Phillips and his team working in Bragg's own laboratory. It should not be concluded from this example that things always happen more rapidly than one expects. For example, the collinearity of the gene with the protein for which it codes took a longer time to prove than we had estimated.

Naturally, as the time over which one is trying to forecast gets longer, so the problem becomes more difficult. One way of tackling this subject is to look back and try to imagine that one had made forecasts in the past about important scientific discoveries. It is easy to show that many important discoveries are of a rather unexpected nature and therefore are difficult to foresee. A good example is the work of Avery and his colleagues which showed that DNA was the chemical molecule involved in transforming *Pneumococcus*, or the discovery of Lederberg and Tatum of genetic recombination in bacteria. One would have had to be far sighted indeed to predict these discoveries more than a few years before they were made, or to realize the tremendous importance which time has shown them to hold. For this reason forecasts of fifty years or more are very difficult indeed and I feel they are hardly worth making. For a period of twenty-five years one might hope to have some success. I have therefore arbitrarily taken a period of thirty years, which brings me nicely to the year 2000.

Big Increase Likely

I shall argue that there are certain general factors which make it virtually certain that there will be a big increase in biological knowledge during this period. In the first place there is a very considerable amount of manpower available, not only at present but also on an even greater scale in the future. At the moment it is fair to say that most biological research is concentrated in the United States and parts of Western Europe, with significant contributions from the USSR and from Japan. In fact, the amount of effort seems to be strongly correlated with the standard of living. Because there are many countries in the world with a standard of living which is likely to increase, we can expect further countries to start contributing to biological research. In particular, it would not be surprising if eventually China became a major scientific power.

Until a few years ago it was possible to believe that the funds available for scientific research in any one of the advanced countries were continually increasing. A perfectly general argument shows that this rate of increase cannot be sustained over a long period and eventually saturation must set in. We are perhaps already seeing the beginning of this process in the United States, although it has been partly brought about by the war in Vietnam. From a broad point of view, however, we can be reasonably confident that, short of some nuclear catastrophe, there will be large sums of money and very large numbers of people available for biological research.

Not only are biologists themselves increasing in number, but fairly large numbers of people are moving into biology from other scientific disciplines. There is an interesting distinction that can be made here between problems and techniques. For problems, scientists seem to move upwards in the scale of complexity. That is to say, they go from physics and chemistry into molecular biology and from molecular biology into cell biology and so on. For techniques it is quite a different matter and one may find people borrowing techniques in any direction. Modern biologists are quite at home using recently developed techniques springing from the physical sciences. In spite of this it is rare for biologists to leave biology and take up problems in chemistry and physics proper.

* I do not wish to make a strong distinction between molecular and cell biology. In one or two places I have referred to other branches of biological research, on the rather doubtful grounds that molecular biology can be defined as anything that interests molecular biologists.

One result of this migration of people from the so-called more exact sciences has been the confidence which they have brought to the study of biological problems. Physics and chemistry within the past seventy years have been immensely successful and have not only revolutionized the detailed knowledge of these subjects, but have also produced theoretical foundations of great power and subtlety. Physicists in particular have been living in a revolution for so long that it has become almost second nature for them to think of their subject in this way. It is therefore not surprising that physicists who move into molecular biology have often seemed rather brash and over-confident in their approach to biological problems. In spite of the distress this may have caused to biologists proper, it has to be conceded that very great advances have been made in molecular biology from just such a point of view.

Influence of Physics and Chemistry

Another extremely important factor, which I sometimes feel is not sufficiently appreciated, has been the tremendous power of modern experimental techniques, mostly springing from physics or physical chemistry. One has only to consider such examples as chromatography, the use of radioactive tracers or the electron microscope (to mention only a few) to see how powerful and how various they are. A molecular biologist called upon to tackle almost any problem which would interest him now, using the techniques available before, say, 1935, would give up, I think, in despair. Moreover, there is little sign of the exhaustion of any one technique and there are still signs that new techniques are coming along—for example, the use of nuclear magnetic resonance on the one hand and of computers on the other. Although no one would pretend that we have techniques to solve all the problems which face us, nevertheless, there is a general feeling that either the existing techniques, or such new ones as can be generated by ingenuity and by a resolute confrontation of the problem, will be enough to see us through.

When we turn to look at the nature of biology itself we see stretching before us an almost unlimited number of important, interesting and unsolved problems. This is partly due to the inherent complexity of biology and partly due to a passionate desire to understand the world around us and our own natures in particular. There are so many things we should like to know—and like to know about in considerable detail—that we need not seriously worry at this stage that the subject will become exhausted.

For all these reasons then, that there is a large supply of both manpower and money, that very powerful techniques are available and that the problems are of absorbing interest, we can confidently predict that there will be a massive research effort in biology for a good many years to come.

Let us now consider various specific problems, first in molecular biology, and ask what state they will be in by the year 2000. The reader might find it amusing to make his own list of such problems as are closely familiar to him. One might take as examples: a detailed understanding of the replication of DNA and of the unwinding process; the structure of chromosomes; the meaning of those nucleic acid sequences which are not merely an expression of the genetic code but are used for stopping or starting or control mechanisms of one sort or another; the significance of repetitive sequences in DNA and so on. My own conclusion was that no matter what topic one considered, either in classical molecular biology or in such related subjects as oxidative phosphorylation and the structure of mitochondria or even such relatively unexplored fields as the structure of membranes, it was difficult to think of one which would not be solved by the year 2000, at least in outline. The molecular mechanism of muscular contraction; the way in which antibody variety is generated and immunological tolerance produced; the exact way in which hormones act; how synapses are modified during learning . . . all these problems, I feel, will advance very considerably towards definitive solutions by the end of the twentieth century.

Cell Biology

If we now turn to cell biology, a field which I do not know as well, one reaches broadly the same conclusion, although the period might be a little longer—perhaps up to forty or fifty years ahead in some cases. I am thinking of such subjects as: the mechanism and control of mitosis; cell movement, and axon growth in particular; cell recognition (especially as it arises in the nervous system) and also the nature of the influences which produce "gradients" in embryological development.

If the reader should think I am being over-optimistic, let him look back to 1940 and see how much more we know now than we knew then in almost all these subjects. Moreover, this period includes five years of war, during which biological research went on very slowly and for the first half of this period the manpower and money available for biology, though increasing, had still not reached the present high level.

If it be accepted that most of the problems with which we are today rather closely concerned are likely to be solved by the year 2000, it is worth while to consider what problems are likely to remain unsolved. It seems to me there are subjects of a rather general nature which are likely to fall into this class. I certainly believe that, in the intervening years, some progress will be made in them, but I rather doubt if we shall be in a position to see the answers in broad outline, let alone in great detail. Examples of such topics are: the origin of life on Earth; the existence of life on other worlds and communication with other creatures in the galaxy, assuming that they exist. Although I think a vast amount of progress will be made on the understanding of the nervous system, it would not be surprising to me if some of the more sophisticated aspects of the behaviour of the brain still remained a puzzle. I am thinking of such matters as our vivid interior three dimensional picture of the world which we build up from the light signals falling onto our eyes and other information, and also such problems as the nature of consciousness, although whether this will turn out to be a real problem or a semantic one remains to be seen.

There is also a major problem to which I believe biologists have given insufficient attention. All biologists essentially believe that evolution is driven by natural selection, but someone from the more exact sciences could well point out that it has yet to be established that the rate of evolution can be adequately explained by the processes which are familiar to us. It would not surprise me if nature has evolved rather special and ingenious mechanisms so that evolution can proceed at an extremely rapid rate—recombination is an obvious example. It may even be that if we could look back from 100 years ahead, we would realize that what we know today is not adequate to explain the rate which actually occurs. An exact estimate, if we could make it, using present known mechanisms might, for all we know, be out by a factor of 10 or even by one as large as 100. To solve this problem we may need a rather complete knowledge of many biological

systems, both at the molecular level and at the ecological level and at all levels in between. For this reason I doubt if it will become a mature subject within the period we are discussing, although it would be surprising if there were not some initial attacks on it.

In reflecting on which problems are likely to be solved by AD 2000 and which are not, it seems to me that the distinction between the two classes depends mainly on whether they can be attacked by isolating a small part of a biological system, or whether one is mainly concerned with its behaviour as a whole. Molecular biology has been successful largely because it has concentrated on the former type of problem, although certain aspects of the overall behaviour have often been used as a tool. Molecular genetics is an obvious example. But, in the long run, problems involving complex interactions can hardly be avoided, since some of the most profound aspects of biology are of this character. The development of high speed computers will help, but the difficulties are not solely computational. One needs to know so many data in order to make the calculations realistic and not merely plausible. A simple example would be the "total" behaviour of a microorganism such as *Escherichia coli*, including all its regulatory mechanisms. Such a cell can usefully be regarded as a special type of chemical factory, and it is not unreasonable to ask, for example, how efficient its construction is. All the long term problems I have mentioned involve complex interactions, except perhaps that of the origin of life, where the main difficulty is to obtain any direct experimental evidence at all of what happened so long ago.

Finally, one must consider the subjects in between; that is, problems which are not immediately in front of us on the one hand or of such a long term nature that we think they will not be solved by that time. These are by far the hardest to guess, partly because such problems depend on new and unexpected break-throughs of one sort or another. These are certain to occur. One would predict that they may, in part, depend on questions which we have not yet learned to ask. What is not clear is how much of the subject in the future will depend on such break-throughs. It is unlikely to be a negligible fraction. On the other hand, I rather doubt if research in the year 2000 will be entirely dominated by the break-throughs which have taken place in the years between now and then. Of course, it is exactly these unexpected and important developments which make a science exciting for those doing research in it, but one should not lose sight of the fact that even without them much useful science can be done following existing concepts and techniques; even in research of this later kind there will usually be a whole series of minor break-throughs to bolster up the morale and interest of the people doing the work.

New Branches of Science

However, one should consider not merely break-throughs in the existing sciences but the creation of entirely new branches of science which scarcely exist at all at the present day. In the fifties, Watson and I were rather fond of the hypothetical science of astrobotany. This, we felt, was bound to come but it seemed sufficiently far in the future that we could enjoy making jokes about it. What is remarkable is that there has already been a beginning to this study. It now seems unlikely that there will be life of any sort on the Moon and rather doubtful if there will be anything living on Mars, but experiments have already been undertaken to see what terrestrial organisms can survive in the rather bleak conditions found on these heavenly bodies.

I therefore feel an obligation to suggest a new subject in which practically no work has been done at all, and I would propose for your consideration biochemical theology*. It is not quite true that nobody has researched into such matters as the efficacy of prayer. In the last century, for example, Galton† wrote an amusing paper on the subject (Statistical Enquiries into the Efficacy of Prayer) in which he showed by a couple of ingenious statistical tests that the efficacy of prayer seemed to be rather low. This line of work does not appear to have been followed up either by the Church of England or by the Vatican. But nobody, as far as I know, has considered the problem at the biochemical level. So many people pray that one finds it difficult to believe that they do not get some satisfaction from it, and a good molecular biologist will naturally believe that this can be expressed, at least in part, in molecular terms. Part of it, of course, would involve the molecular biology of the synapse and the overall organization of the nervous system, but the principal effect is probably hormonal, and one would not be surprised to find that hormone levels were affected by prayer. No doubt before long some "with-it" church in America will take up the topic.

Today's Problems Solved

My broad conclusions, then, are that between now and the year 2000 biological research will take place on a massive scale. By then, most of the detailed problems in molecular and cell biology facing us now are likely to be solved. Certain broad but important subjects will still be in a primitive stage and there will inevitably be a proportion of novel, unexpected and significant advances the nature of which we can hardly guess. In short, the whole field is likely to be even more fascinating in the year 2000 than it is today.

Finally, I feel one should consider briefly the role of *Nature* in these developments. In the past, *Nature* has been very friendly to molecular biology, as it has to several other border-line subjects. The advantages of wide distribution and rapid publication have not gone unnoticed by people struggling to make a way for themselves in the areas between the existing scientific disciplines. Moreover, in the past few years, the standard of editorial comment on work in molecular biology has been very high and a series of correspondents have helped to keep the readers of *Nature* in touch with work published in other journals. I hope, however, that *Nature* will not become overloaded with too many detailed papers in what we now regard as the more classical parts of molecular biology. There is a need for a journal with a wide circulation containing general articles on various scientific topics which can be read with advantage and pleasure by people not working in those particular fields, in addition to papers, hot from the research front, for specialists. We are all grateful to the support that *Nature* has given to the development of our subject.

* Recently I was idly glancing at the novel *Antic Hay* by Aldous Huxley when, on the first page, I came across the following: "But if theology and theosophy, then why not theography and theometry, why not theognomy, theotrophy, theotomy, theogamy? Why not theophysics and theo-chemistry?" They form part of the musing of Theodore Gumbril Junior in the opening scene in the chapel, during which, because of the hardness of the seats, he first conceived the idea of the Patent Small-Clothes, the trousers with the inflatable seat which can be blown up or deflated at will. *Antic Hay* was first published in 1923, and I must have read Gumbril's ruminations when I was an undergraduate, or even earlier. I should point out, however, that there is a profound difference between theological biochemistry and biochemical theology. Curiously enough, I think theo-chemistry probably corresponds to the latter.

Micrometeorite Environment at the Earth's Orbit

by
J. F. KERRIDGE*
Geological Research Division,
Scripps Institution of Oceanography,
La Jolla, California 92037

Space vehicles have revealed the broad outlines of the micrometeorite mass distribution at one astronomical unit from the Sun, although some uncertainties remain. But we still know nothing about their composition and have only scant data about their origin. Such data as exist support a cometary origin for micrometeorites, in accord with most recent theoretical work.

BASICALLY micrometeorite experiments have been designed to answer one or more of the following three questions. How many are there? What are they made of? And where do they come from? We are well on the way to answering the first question and progress is being made on the third. The second, however, is a long way from solution. In this article I shall consider the experimental data on the population of sub-microgram particles in interplanetary space in the light of these questions. Theoretical questions have received adequate treatment elsewhere[1–4]. The cutoff point for this study at one microgram represents approximately the effective upper limit for satellite experiments and the lower limit for radio meteor observations[3,5,6].

Mass Distribution of Micrometeorites

Ground-based observations of the mass distribution of particles in this size range are restricted to analyses of the extent, brightness and polarization of the zodiacal light and gegenschein[7–9]. These data can be interpreted, with the aid of a suitable physical model for the nature of the scattering particles, in terms of a mass distribution[10,11]. Such a model is based on parameters such as the particle shape and albedo, which are known with less precision than is the mass distribution. Published mass distributions which have been based on zodiacal light or gegenschein observations therefore will not be reviewed here although orbital data based on these observations will be considered in answer to the third question.

A ground-based measurement which should be mentioned in this context, although it does not lead to a mass distribution, is the determination of ^{26}Al produced by cosmic radiation in deep sea sediments and Arctic ice[12–15]. From this quantity and assumptions about the mean cosmic ray flux, composition of the irradiated interplanetary dust and the orbital lifetimes of such particles, a value can be obtained for the total mass falling on the Earth per unit time in the form of dust[16]. Yokoyama has calculated an absolute upper limit to this mass of 1,000 tons per day with a probable upper limit of 100 tons per day[17], in broad agreement with the results from direct measurement of the mass distribution by means of space vehicles.

Virtually every kind of space vehicle has been used to carry experiments designed to measure the mass distribution of micrometeorites, but the yield of hard facts from the large amount of raw data has been disappointingly small. No results will be presented here from collection experiments mounted on aircraft or balloons for reasons mainly to do with contamination. Consequently the only reliable source of data from which to compute a micrometeorite mass distribution is the satellite-mounted experiment, and I have made a critical study of the results of all such experiments which could be found in the literature. I have selected from a great many experiments those which were felt to be most reliable, and to this end certain criteria were established against which each experiment and its data were measured.

First, the original data, in terms of number of micrometeorite impact events recorded, measured noise level, timing and duration of experiment, altitude and attitude of the vehicle and so on, had to be available so that independent flux calculations could be made. Second, the experimental unit should have been calibrated using a high-velocity, or preferably a hyper-velocity, facility in order to simulate micrometeorite impacts more closely. Actually in no case was the calibration procedure entirely satisfactory. The most common calibration device in recent years has been the Van de Graaff accelerator equipped with a particle injection mechanism of the kind developed at the TRW laboratory[18]. Although the Van de Graaff has enabled at least the lower end of the micrometeorite velocity spectrum to be simulated in the laboratory, many of the calibrations have suffered from two drawbacks. First, the particle filters, used to prevent more than one particle from impacting the detector at one time, have been inefficient and have allowed clusters of particles to pass into the test chamber. Second, although a small amount of work has been done using graphite particles, in order to simulate more closely the low densities thought to be characteristic of micrometeorites, by far the most common projectile material has been iron and this may be a source of error in the calibrations.

The third criterion for acceptance was freedom from known sources of noise. This was clearly a more subjective test than the others and at first it was planned to use only data from coincidence systems or experiments involving some other kind of reliable discrimination against spurious signals. Coincidence systems are those in which each micrometeorite event is recorded simultaneously by two or more transducers of different types, such as an ionization detector coupled with an acoustic sensor. Unfortunately insufficient results are available from such experiments to provide a statistically meaningful survey of the mass range of interest so that some of the more reliable single-transducer systems were also included in the results.

Fig. 1 presents the results from eight experiments which satisfied the criteria. I have followed the convention of plotting the data as a cumulative mass distribution, so that a point at mass M corresponds to the flux through unit area in unit time of micrometeorites with mass equal to or larger than M. It should be noted that, with the exception of the Gemini S-010 points, each datum point represents the number of micrometeorite impact events which exceeded a certain threshold value as most detectors used so far have had no dynamic range. The error bars correspond to one standard deviation of the recorded number of impacts and represent a measure of statistical

* Present address: Planetology Branch, NASA Ames Research Center, Moffett Field, California 94035.

strength only. It is not possible to assign error limits to mass values because of the uncertainties in calibration procedures. The line drawn through the data points is an extrapolation by eye of the radio meteor flux given by Whipple[3] which is drawn here as a definitive line though it should be noted that this, too, is the result of experimental observation and thus liable to error. For complete technical details reference should be made to the appropriate publications, but some remarks about the different systems are necessary.

The Pegasus experiment achieved an effective dynamic range corresponding to a factor of about thirty in mass by the use of three detectors of different sensitivities[19]. The large size of this experiment ensured that it recorded a great many impacts, and it is statistically very reliable. Early problems with poor calibration of the detectors have been resolved by a careful programme of hypervelocity firings so that the mass values associated with the impact data are now equivalent in reliability to those of other experiments[20].

Explorer 23 carried several micrometeorite impact experiments of which only the pressure cell system is considered here[21]. The same system was carried also on Explorer 16, but the results are essentially equivalent so that only data from the later experiment have been used. The same comments concerning calibration are valid here as in the case of Pegasus[20].

The Gemini S-010 experiment[22], in which polished stainless steel plates were exposed to space aboard Agena target vehicles, possessed the greatest dynamic range of the experiments considered here. The system was potentially capable of recording impacts over virtually the entire micrometeorite mass range, the upper limit being governed by available exposure time. But in the case of the only recovered experiment, thruster debris and handling by astronauts created a background which obliterated impact sites corresponding to masses below about 10^{-11} g. Because of the relatively small area of the experiment there were few impacts, which reduced the statistical reliability of the data.

Although acoustic sensors have received a certain amount of criticism[23], centring on their sensitivity to noise of thermal and electronic origin, very carefully controlled systems were flown on Cosmos 135 and 316 (refs. 24 and 25). An acoustically isolated sensor was used to record micrometeorite impacts while a separate sensor, attached to the spacecraft structure, monitored the noise level. As a result the count rate data are thought to be reliable although these experiments were calibrated by bead dropping and consequently their mass sensitivities must be regarded with caution. The Cosmos 163 experiment was actually a coincidence system, involving a thin film capacitor in addition to the acoustic sensor. Malfunction of the capacitor resulted in only acoustic data being obtained[25], however.

An operational coincidence system was carried on Explorer 35, consisting also of a thin film capacitor coupled with an acoustic sensor[26]. The output from this system is thought to be reliably free from noise.

The Mariner 4 micrometeorite sensor was another coincidence system in which the thin film capacitor failed to function, leaving only the acoustic data[27]. Although the noise level in this experiment was not monitored as it was in Cosmos 163, the data are felt to be reliable because of the stable thermal environment which the sensor experienced and there is no evidence that this system gave a spuriously high impact rate[28].

The detector system included in Pioneer 8 and 9 must be considered the best micrometeorite experiment yet flown[29]. In this system the micrometeorite velocity is measured directly by a time-of-flight device, its energy is measured by the output from a thin-film plasma detector, its momentum is registered by means of an acoustic transducer and finally its radiant can be determined by correlating the end points of the time-of-flight measurement. Thus the true mass of the micrometeorite can be calculated, whereas in all other experiments it was necessary to derive an effective mass based on an assumed mean micrometeorite velocity, sensor outputs being usually some function of both mass and velocity of the impacting particle. The high level of redundancy in the system also ensures that the data are virtually free of unidentified noise so that, although the count rate from these spacecraft is extremely low (nine time-of-flight measurements in more than two years), the derived flux rate is extremely reliable[30]. Finally, it should be noted that the Pioneer 8/9 experiment has an appreciable dynamic range corresponding to more than two orders of magnitude in particle kinetic energy. With the observed velocities this has resulted in a mass range of a little more than one order of magnitude. For direct comparison with the other results the Pioneer 8/9 data were degraded by reducing the real masses measured by that experiment into effective masses equivalent to those derived for the other systems.

Following the recommendation of the Cosmic Dust Panel of COSPAR, a mean value of 20 km s^{-1}, derived from radio meteor observations, has been used to compute an effective mass corresponding to each detector signal. If micrometeorite velocities are found to vary appreciably from this mean the physical significance of the computed effective masses will be clearly reduced. In fact, Pioneer 8 and 9 have measured velocities, relative to the spacecraft, of from 5·7 to 35·9 km s^{-1} (ref. 30). The significance of the effective mass is further diminished as a result of the calibration methods commonly used. Virtually all calibrations have been performed using impacting particles at normal incidence whereas in reality incident angle varies over an appreciable solid angle, frequently as much as 2π steradian. Thus, even neglecting the velocity problem al-

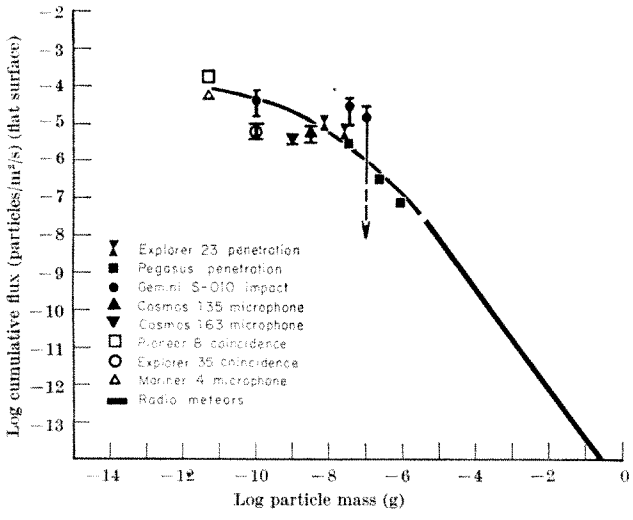

Fig. 1. The mass distribution of micrometeorites at a heliocentric distance of approximately 1 astronomical unit, expressed as a cumulative flux through a flat surface. Solid symbols represent measurements in Earth orbit, open symbols correspond to either lunar orbit (Explorer 35) or locations away from the Earth–Moon system.

ready referred to, the effective mass usually corresponds to the low end of a range of real particle masses, the extent of this range depending on the directional sensitivity of the detector concerned. It follows that, because detector response as a function of incident angle is not known usually, the flat surface flux as measured cannot be converted into a solid angle flux.

The data in Fig. 1 were all obtained at a heliocentric distance of approximately 1 astronomical unit. Solid symbols correspond to detector systems which were in Earth orbit, open symbols to those which were either in lunar orbit (Explorer 35) or away from the Earth–Moon system. Within the accuracy of the data no significant difference between different locations can be seen. An accretion rate of approximately 20 tons per day over the Earth's surface can be inferred.

Fig. 1 suggests several areas for future investigation. First, although the agreement between different experiments is now better than in the past, there are still discrepancies, some of which must be attributed to the comparison of data derived from different functions of the micrometeorite's properties, momentum and kinetic energy, for example. Second, overall determination of the shape of the mass distribution curve strictly requires the use of an experiment with sufficient dynamic range to cover the mass range of interest, in this case from some unknown lower limit up to about 10^{-6} g. Third, the data give no information about any particles which might exist smaller than about 5×10^{-11} g. Although satellite data pertaining to particles down to about 10^{-15} g do exist, none of them met the criteria given earlier so that this mass range should be regarded as unexplored. The Pioneer 8/9 data have been interpreted to show a real mass cutoff at about 5×10^{-12} g (ref. 30). Extension of this observation to the conclusion that no smaller solid particles exist in appreciable numbers in the solar system, however, involves the assumption of a monotonic distribution curve for which there seems to be no good evidence. Consequently it is worthwhile to obtain data on the population of particles in the mass range 10^{-15} g (an arbitrary lower limit) to 10^{-11} g. A fourth observation concerns the comments made earlier about the drawbacks of a distribution curve based on effective rather than real mass. It would seem that, if there are experiments which can give real mass data (plus real velocity and so on), there can be little justification for flying detectors which yield only effective mass data. With these observations in mind, three kinds of experiment are suggested as being potentially useful for increasing knowledge of the micrometeorite mass distribution.

First, the Pioneer 8/9 experiment has been proved to be a system capable of yielding noise-free data on real masses for a small but nonetheless useful mass range. Its only drawback so far seems to be the slow rate at which data are collected, a problem which could be solved by putting more units into space. In particular, a proven unit such as this would seem to be the logical choice for incorporation aboard spacecraft destined to explore new regions of the solar system, such as the asteroid belt. It would be useful to place one or more such units in Earth orbit to check more precisely the apparent absence of a dust belt around the Earth[1,31,32]. At present the experimental evidence depends on comparisons between different experiments.

Second, another kind of remote sensor which will apparently be capable of providing real mass data is the ionization detector which will be discussed in more detail in the next section. Although not a time-of-flight sensor, this detector produces one signal which seems to be a function of velocity only, plus another which is a function of both mass and velocity. Thus a real mass determination is theoretically possible. Such units are being developed in several laboratories, among them the Max-Planck-Institut für Kernphysik at Heidelberg and the University of Birmingham.

Third, the exposure to space and recovery of suitably prepared surfaces provides a method of obtaining a greater dynamic range than either of the foregoing at the expense of reduced resolution of mass and velocity. In such a study, which depends on the microscopic examination of impact sites produced in surfaces by micrometeorites, laboratory simulation experiments[33] have shown that, although the crater volume is a function of both mass and velocity, the diameter-to-depth ratio of the crater is apparently independent of mass and a function only of velocity, thus providing for a unique determination of each parameter. By a suitable combination of electron and optical microscopy, impact sites from less than 100 Å in size to an upper limit fixed only by the thickness of the sampling material or the duration of the exposure can be covered.

It can be concluded that the mass distribution of micrometeorites in our part of the solar system is reasonably well understood and that five to ten years, depending on funding levels, should see the remaining uncertainties resolved.

Composition of Micrometeorites

The determination of the elements or phases which make up micrometeorites is much less satisfactory. If criteria, similar to those of the last section, are applied to past and current experimental work, no firm conclusions can be drawn as to micrometeorite composition. These experiments have fallen into four categories: atmospheric collections (refs. 34 and 35 and paper by Brownlee and Hodge at Meteoritical Society Meeting 1969), rocket collections[36–38], recoverable spacecraft collections[22,38,39], and analysis of crater residues in recovered surfaces[40,41].

The first two categories suffer from the problems of contamination referred to previously. These are sufficiently severe to make identification of each micrometeorite impossible unless some intrinsic property is taken as proof of extraterrestrial origin. Clearly such an identification process automatically biases the results. Collection experiments mounted aboard recoverable spacecraft have been unsuccessful because the high velocity of cosmic particles has prevented them from surviving impact with the collection surface. In the case of a solid surface this impact produces a crater, and in the fourth category of experiment the electron microprobe has been used to analyse the residue left inside such a crater[40,41]. Although this technique has yielded semiquantitative compositional data on the material in the Gemini S–010 craters referred to earlier[41], some degree of fractionation probably occurred during the impact volatilization and consequently the residual composition is unlikely to be that of the original particle. The technique is of course blind to the elements making up the original surface.

So far no remote sensors have been flown capable of yielding compositional information. The next few years, however, should see the introduction of systems designed to provide *in situ* analyses of micrometeorites. The most promising of these are the ionization detectors referred to previously. In this technique a plasma pulse is produced at the site of a micrometeorite impact, the energy for

plasma formation being provided by the particle's kinetic energy. A system of electrodes close to the target surface separates ions from electrons in the plasma and the ions are then passed down a time-of-flight mass spectrometer[42].

Origin of Micrometeorites

There are three obvious sources for the production of interplanetary dust particles: comets, asteroids and interstellar dust. The objective of micrometeorite orbital determinations is to distinguish between them. Theoretical considerations have suggested that comets are the dominant source of micrometeorites in the solar system[3,4].

Zodiacal light isophots can be analysed in terms of an average value for the inclinations of the scattering particles[2]. This analysis is less dependent on assumptions as to the shape, albedo, and so on of the particles than is the mass distribution discussed earlier. A mean value of 30° has been derived for the inclination of the zodiacal particles, significantly greater than the mean for either short period comets (15°) or asteroids (9·7°). This suggests the existence of an efficient perturbing force acting on particle inclinations[2].

Although a single orbital determination on a meteorite, especially if taken in conjunction with a cosmic ray exposure age, may be of considerable genetical significance, in the case of a micrometeorite its greatly increased probability of orbital perturbation drastically reduces the significance of its orbit at any moment in time. The only meaningful way to obtain such data is to search for statistical trends among large numbers of orbital determinations and at present such determinations are few in number. The only directly measured orbital parameters have been obtained by Pioneer 8/9 (ref. 30). Although preliminary, these data have been interpreted as supporting a cometary origin. Two of the eight orbits so far coincide with actual comet orbits. Because of the low inclination of the spacecraft orbit the observations are biased towards micrometeorites in low inclination orbits. Considering the other measured parameters, however, the data are in agreement with meteor observations which have suggested positive correlations between particle mass on the one hand and semi-major axis, eccentricity and perihelion distance on the other[5,30,43,44]. It is clear, though, that more data are required before firm conclusions can be drawn regarding the original orbits of micrometeorites.

Little to Show so far

In spite of the expenditure of considerable time and money during the past fifteen years, the corpus of knowledge concerning the micrometeorite population in our part of the solar system is disappointingly small. Several factors might be responsible for this state of affairs. First, the design and construction of reliable, low-noise detection systems require the marriage of a number of sophisticated disciplines not often to be found in one laboratory.

Second, the importance of hyper-velocity calibration was late in being appreciated and it is now apparent that such calibration procedures are not only technologically difficult but also extremely expensive. A Van de Graaff accelerator equipped with adequate particle injection and filtering devices costs virtually as much as a small satellite.

Third, most attempts at direct measurement of micrometeorite flux have been influenced by the desire to provide estimates of spacecraft hazard. Consequently the emphasis has been on acquiring technical performance parameters which have subsequently been interpreted, with difficulty, to yield some scientific data concerning the micrometeorites themselves. It is obvious that, had the experiment been designed originally to provide scientific parameters such as mass and velocity, these could have readily been converted into estimates of spacecraft puncture probability.

It is to be hoped that the rather poor returns in this field so far do not inhibit further investment just at a time when adequately sophisticated experimental techniques are becoming available.

The study described here was performed while I was at the Dudley Observatory, Albany, New York. I thank the director, Dr C. L. Hemenway, for his encouragement and NASA for a research grant.

Cooperation of Immune Lymphoid Cells with Macrophages in Tumour Immunity

by

R. EVANS
P. ALEXANDER

Chester Beatty Research Institute,
Belmont, Sutton, Surrey

An immunologically specific cellular cooperation may resolve the paradox that immune spleen cells injected into normal mice prevent the growth of lymphoma cells *in vivo* but fail to do so *in vitro*.

CELLS of the L5178Y murine lymphoma carry tumour-specific transplantation-type antigens in their plasma membrane, and syngeneic DBA/2 mice become resistant to challenge by this tumour after a single immunization with L5178Y cells which have been rendered incapable of growth by exposure to X-rays[1,2]. This resistance can be transferred to untreated mice by spleen[1] and lymph node[3] cells from immune mice, but when tested *in vitro* neither the serum nor the spleen cells from such immune mice are cytotoxic or growth inhibitory to L5178Y cells. Inability to detect *in vitro* the direct cytotoxic action of syngeneic spleen cells is probably not the result of a technical failure, for the cytotoxic action of allogeneic immune spleen cells (for example, from C57/Bl or CBA mice immunized with L5178Y cells) has been readily demonstrated *in vitro*[1,4,5] and indeed the L5178Y system is one of the most convenient for studying the activity of cytotoxic lymphoid cells. The apparent paradox that immune syngeneic spleen cells can transfer activity *in vivo* but are inactive by themselves *in vitro* suggests the possibility that to destroy the L5178Y cells in the syngeneic system the immune lymphoid cells must act in cooperation with another cell. In an analogous situation in which resistance to infection by *Listeria monocytogenes* was transferred to recipient mice by spleen cells from mice immunized against the bacterium, the evidence suggested an interaction between lymphoid cells and macrophages, the latter providing the mechanism by which resistance was expressed[6,7].

We here describe experiments intended to demonstrate, first, that syngeneic peritoneal macrophages from mice immunized against L5178Y cells exert a cytotoxic effect on lymphoma cells *in vitro* and, second, that normal syngeneic macrophages may be rendered cytotoxic towards lymphoma cells following incubation with immune spleen cells.

Peritoneal exudate cells were obtained from DBA/2 mice by syringing out the cavity with Fischer's medium[1]; cultures were prepared by seeding approximately 2×10^6 macrophages into 3·5 cm Falcon plastic Petri dishes. After 15 min the medium was decanted and 2 ml. of Fischer's medium supplemented with 10 per cent heat-inactivated foetal bovine serum (FM) was added. Cultures were then incubated for 2 h, after which most of the lymphocytes present were removed by intensive washing of the monolayer with jets of tissue culture fluid. At this stage lymphocytes constituted less than 3 per cent and granulocytes—for example mast cells—less than 0·1 per cent of the culture.

Fig. 1 illustrates the growth curves of $5{\cdot}0 \times 10^4$ L5178Y cells—as determined by counting in a haemocytometer—in 2 ml. of FM when placed on such monolayers of macrophages. Although macrophages from non-immune mice were without effect on their growth, cell division was completely inhibited in the presence of immune macrophages, and the lymphoma cells began to disintegrate after 1 day. In this experiment the ratio of macrophages to L5178Y cells was 40 : 1 but effective cytotoxicity was also observed at ratios as low as 10 : 1 (see Fig. 2).

We summarize the characteristics of this reaction as follows: (1) it is immunologically specific and macrophages from DBA/2 mice immunized with BCG, with another lymphoma or after stimulation with Difco thioglycollate medium, were without effect on growth of the lymphoma. (2) The addition of complement from rabbit and rat sera was without effect. (3) The lymphoma cells were killed apparently by cell contact with the macrophages (a similar type of interaction was first described by Granger and Weiser[8] in an allogeneic system) and a confluent monolayer was essential for maximum inhibition of growth of lymphoma cells; phagocytosis only occurred after 24 h when the cells began to degenerate and in this respect this system is quite different from the intracellular killing of tumour cells by macrophages reported by Bennett, Old and Boyse[9] which required an opsonizing antibody. (4) The cells had to be in contact with the immune macrophages to be irreversibly damaged; for example, after 4 and 24 h, lymphoma cells washed off macrophage cultures grew normally when transferred into fresh dishes. (5) The medium recovered from cultures of immune macrophages previously exposed to lymphoma cells had no effect on the growth of lymphoma cells. (6) The number of contaminating lymphocytes was reduced to less than 1 per 1,000 macrophages by irradiating the monolayers of peritoneal cells with 400 r of X-rays *in vitro* before adding lymphoma cells. (The purified macrophage monolayers obtained in this way were fully cytotoxic.)

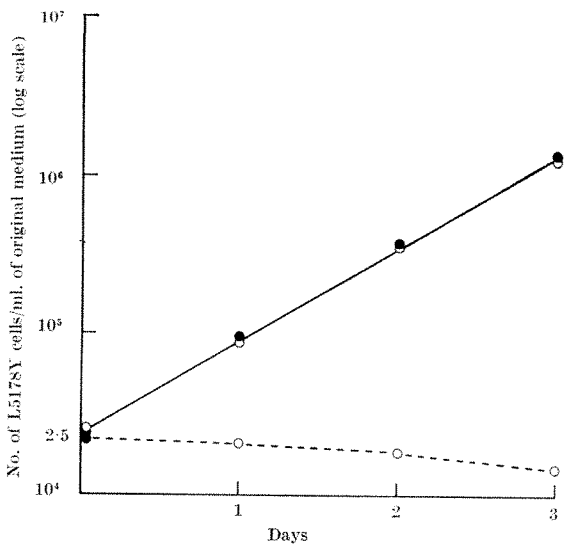

Fig. 1. Effect of immune macrophages on growth of lymphoma L5178Y cells *in vitro*. The culture medium was supplemented at daily intervals. ○—○, No macrophages; ○ - - - ○, immune macrophages; ●—●, non-immune control macrophages.

(7) Cytotoxicity was not reduced when the contaminating mast cells were removed by exposing the peritoneal exudate cells to 1·0 μg/ml. of the polyamine '48/80' (Burroughs Wellcome) which lyses mast cells[10]. (8) Monolayers of immune macrophages retained their cytotoxic action if maintained for 2 days but not if they were maintained for 7 days in culture before the lymphoma cells were added. (9) Macrophages were cytotoxic if removed from mice at any time between 3 and 21 days after two injections of irradiated cells or between 3 and 40 days after three of four injections, but after single intraperitoneal immunization with 5×10^6 irradiated lymphoma cells peritoneal macrophages were cytotoxic only if removed on day 11, and were not so if taken on days 7 or 14 after immunization. (10) By injecting thioglycollate medium 6 days before removing the peritoneal exudate cells from hyper-immunized mice, the number of macrophages in the peritoneal cavity was increased five to ten times but in spite of the greater number of macrophages which became available in this way the cells retained their full cytotoxic effect; that is, the exudate from immunized animals was not diluted and the thioglycollate medium induced the appearance of more cytotoxic macrophages. (11) Finally, monolayers of immune macrophages after they had been in contact for 1 day with lymphoma cells lost their cytotoxicity and did not retard the growth of a second inoculum of lymphoma cells.

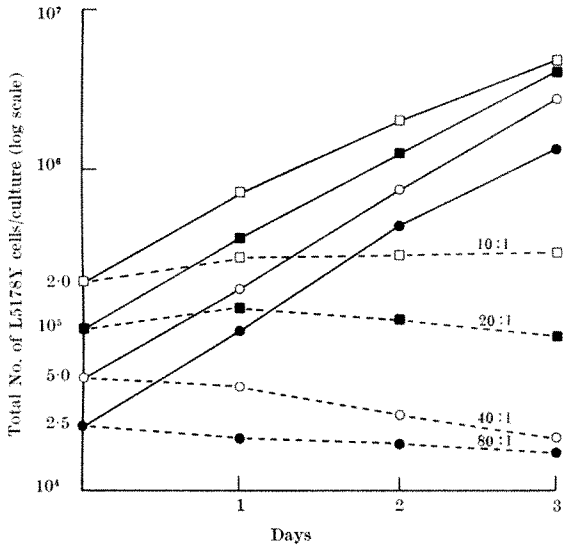

Fig. 2. The relationship between growth inhibition by immune macrophages and the inoculum of L5178Y cells. The number of macrophages remained constant: 2×10^5 per dish.

As already mentioned, spleen cells from DBA/2 mice immunized with irradiated lymphoma cells have no effect on the growth of lymphoma cells *in vitro* even when added to ratios as high as 1,000 : 1 (ref. 1 and footnote*). But the addition of such spleen cells to normal non-immune, peritoneal macrophages renders these cytotoxic. Fig. 3 illustrates an experiment in which lymphoma cells failed to grow, and subsequently degenerated, in normal macrophage cultures which had been incubated for 24 h with immune spleen cells and then thoroughly washed before the addition of lymphoma cells. Neither the non-immune macrophages nor the immune spleen cells by themselves were cytotoxic. Thus contact with immune spleen cells bestowed on peritoneal macrophages the capacity to inhibit growth of lymphoma cells, and

* Because such immune spleen cell suspensions contain as many as 5–10 per cent macrophages their failure to inhibit growth may correspond to the need of the target cells to meet a confluent monolayer or to a qualitative difference between spleen and peritoneal macrophages. In an allogeneic combination when immune spleen cells are cytotoxic *in vitro* the macrophages present do not contribute to this reaction[5].

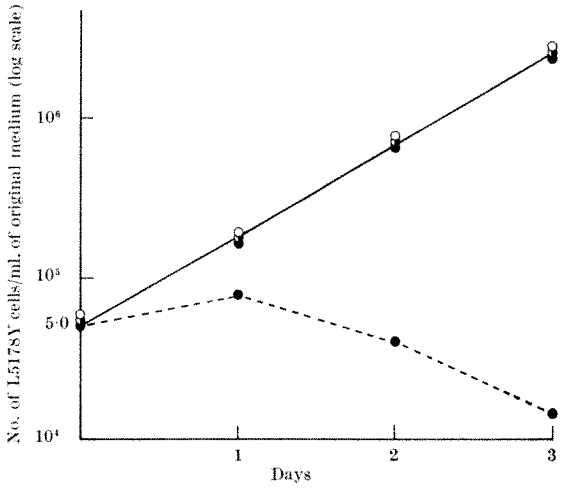

Fig. 3. The effect on growth of L5178Y cells by non-immune macrophages pre-incubated with immune spleen cells (5×10^6 pre-incubated for 24 h with non-immune macrophages and then washed off). ○—○, Culture medium only; ◑—◑, immune spleen cells only; ●—●, non-immune control macrophages; ● - - - ●, non-immune macrophages + immune spleen cells.

such "armed" macrophages could not be distinguished in this test from peritoneal macrophages obtained from immunized mice. This phenomenon is immunologically specific and has only been obtained with spleen cells from DBA/2 mice immunized with L5178Y cells. These experiments may resolve the paradox that immune spleen cells when injected into normal mice are able to prevent the growth of lymphoma cells *in vivo* but by themselves are unable to do so *in vitro*.

We are trying to determine the nature of the interaction between the spleen cells and the peritoneal macrophages and in particular to discover if transfer of an antibody-like molecule is involved. Serum from mice immunized with irradiated L5178Y cells as well as the supernatant from cultures of immune spleen cells has so far failed to render peritoneal macrophages from non-immune animals cytotoxic. The failure to find an immunologically specific humoral factor in these experiments does not exclude the possibility that cytophilic antibody produced by spleen cells is involved (see ref. 11). If such antibody has a very high affinity for peritoneal macrophages or their precursors it may be taken up so effectively *in vivo* that the amount which remains in the circulation is too low to be detected.

In view of the inability of either immune spleen cells or non-immune peritoneal macrophages to affect growth *in vitro* of lymphoma cells, the syngeneic system we have studied made it possible to demonstrate very clearly co-operation between these two components leading to a cytotoxic reaction. The same phenomenon probably also occurs in the rejection of some allografts, but because the immune lymphoid cells are toxic by themselves to allogeneic target cells an enhanced effect resulting from cooperation with macrophages will be more difficult to recognize.

These experiments may have some bearing on immunotherapy of tumours. The growth of tumours, in spite of the fact that they are immunogenic, has been attributed to a failure of the host to produce sufficient cytotoxic lymphoid cells[12,13] and attempts at immunotherapy have been designed to overcome this defect[14]. If immune lymphoid cells cooperate with macrophages, in some conditions availability of the latter may determine whether host defences fail or succeed in containing the tumour. Recent observations in man[15] and in guinea-pigs[16] that some skin tumours regress as a by-product of a non-related delayed hypersensitivity reaction could be interpreted in this way, as might the regression of dermal deposits of malignant melanoma following inoculation with vaccinia virus[17].

Light Inactivation of Focus Formation by Chicken Embryo Fibroblasts infected with Avian Sarcoma Virus in the Presence of 5-Bromodeoxyuridine

by
DAVID BOETTIGER
HOWARD M. TEMIN
McArdle Laboratory,
University of Wisconsin,
Madison, Wisconsin 53706

When RNA tumour viruses infect cells growing in the presence of 5BUdR, exposure to visible light inactivates the virus. This confirms that synthesis of DNA from viral RNA is necessary for viral transformation.

THE RNA tumour viruses (leucoviruses) seem to have a different mode of replication from other RNA-containing viruses. The replication of RNA tumour viruses is sensitive to inhibitors of DNA synthesis early in infection[1,2]; virus production by converted cells is sensitive to actinomycin D (refs. 2 and 3); and viral RNA seems to have a greater homology with DNA from converted cells than with DNA from uninfected cells[4,5]. These observations are summarized in the DNA provirus hypothesis[6]: following infection, the viral RNA is transcribed into DNA and maintained as DNA in subsequent cell generations.

Cells grown in the presence of 5-bromodeoxyuridine (5BUdR) incorporate this analogue into their DNA. This substituted DNA is more sensitive to inactivation by ultraviolet and short wavelength visible light than is unsubstituted DNA[7,8]. Kao and Puck[9] used this sensitization to select against animal cells which could undergo DNA synthesis in deficient media.

The DNA provirus hypothesis predicts that a new DNA is formed soon after infection. If this new DNA could be labelled with 5BUdR, the infection could be aborted by visible light. In addition, the 5BUdR might provide a means to separate the new DNA from cellular DNA, and thus aid in its isolation. To avoid killing cells by the exposure to light, the incorporation of 5BUdR into essential cellular DNA must be reduced. This reduction can be accomplished by maintaining the cells for several days in medium without serum, which collects the cells in the G_1-phase of the cell cycle[10–12] and reduces the number of cells entering S-phase (nuclear DNA synthesis) to 1 to 5 per cent over a 24 h period. (A similar approach is being used by Balduzzi and Morgan, personal communication.)

In preliminary experiments, stationary cultures of chicken embryo fibroblasts were infected with 100 to 1,000 focus-forming units (f.f.u.) of the avian sarcoma virus, B77, in the presence of 5BUdR (ref. 6). Focus formation was inactivated in proportion to the amount of subsequent exposure to visible light following 5BUdR treatment. (Earlier experiments suggested that treatment of stationary cultures of chicken cells with 5BUdR immediately after infection inhibited focus formation[12] but we did not observe this. The two experiments differed because here the serum-containing media were added to the cultures immediately after the removal of the 5BUdR. In the earlier experiments, there was a 24 h delay before addition of serum. It has been shown (unpublished results of D. B.) that there is an exponential loss of focus formation ($t_{\frac{1}{2}} = 9{\cdot}5$ h) during the interval between removal of 5BUdR and addition of serum.)

In these experiments, this technique was modified. Stationary cultures of chicken embryo fibroblasts were exposed to virus, treated with 5BUdR, exposed to light, and replated on a feeder layer of rat cells which are resistant to infection. This assay system gives a linear relationship between the number of foci produced and the multiplicity of infection (at multiplicities of infection of less than 0·1 f.f.u./cell (unpublished results of D. B.)[13]). For a cell to register as a focus in this assay, it must (*a*) contain non-inactivated viral genetic information, and (*b*) be capable of division and conversion. At a multiplicity of infection of 0·1 f.f.u./cell, the inactivation of focus formation by light followed single hit kinetics (Fig. 1). Essentially the same curve of inactivation by light was obtained using concentrations of 5BUdR from 2–500 μg/ml. in the post-infection incubation medium. Similar curves were obtained for cells infected with the B77 or the Schmidt–Ruppin strains of avian sarcoma virus.

In all systems where it has been examined, the effects of 5BUdR result from its incorporation into DNA in place of thymidine[8,14,15]. ^{3}H-5BUdR was used to measure the incorporation of 5BUdR into DNA. Cultures of stationary or dividing chicken cells were incubated for 20 h in medium with or without serum containing 1 μCi of ^{3}H-5BUdR. Nucleic acid was separated by a modified Schmidt–Thannhauser procedure. Less than 1 per cent of the perchloric acid precipitable counts were hydrolysed after incubation for 20 h at 37° C in 0·3 M KOH. Thus less than 1 per cent of the incorporated 5BUdR seems to be associated with RNA. Bader has reported a similar result for dividing chicken cells[16]. Also the light sensitization of focus formation induced by 5BUdR was inhibited when thymidine was added to the 5BUdR-containing medium. The 5BUdR sensitization observed in these experiments is therefore probably a direct result of incorporation into DNA.

Table 1. EFFECTS OF 5BUdR

Experiment	5BUdR (per cent)	5BUdR + 30 min exposure to light (per cent)
1. Initiation of DNA synthesis*	80·8	78·2
2. Initiation of cell division†	25	25
3. Relative plating efficiency of cells infected after 5BUdR treatment‡	100	88

* Cultures of stationary cells, infected with 3 f.f.u./cell, treated with 5 μg/ml. 5BUdR and exposed to light were incubated in ^{3}H-thymidine and serum 0–20 h following exposure to light; autoradiograms were made and labelled nuclei counted.

† Cultures of stationary cells were infected, treated with 5BUdR, and exposed to light. Serum was added. 17 h later 5×10^{-7} M colcemid was added; after an additional 8 h, cells arrested in metaphase were counted by phase-contrast microscopy.

‡ As described in the text except that the cells are infected after removal of 5BUdR and before exposure to light.

There are several explanations to account for the inactivation of focus formation by visible light after infection in the presence of 5BUdR: first, the infected cells incorporate 5BUdR into essential cellular DNA and subsequent exposure to light prevents them from dividing; second, some particular fraction of cellular DNA which is essential for cell conversion is replicated on infection, incorporates 5BUdR, and is inactivated by the exposure to light; or third, the virus genetic information is transcribed to a 5BUdR containing DNA which is inactivated on exposure to visible light. Experiments were done to test these hypotheses.

The first hypothesis was examined as shown in Table 1. The ability of cells to respond to the addition of serum by initiating DNA synthesis as examined by autoradiography or to divide as examined by counting cells arrested in metaphase by colcemid was not significantly altered by the exposure to light. When the infection is delayed until after 5BUdR treatment there is no significant change in plating efficiency after exposure to light. The lack of cell killing in these experiments (Table 1) results from the use of cultures of stationary cells in which only 1–5 per cent of the cells pass through S-phase DNA synthesis and incorporate enough 5BUdR to become sensitive to visible light. Thus cell killing and differences in plating efficiency between the cells exposed to light and those unexposed to light could account for only a small portion of the light inactivation of focus formation observed in Fig. 1.

To test the possibility that only potential focus-forming cells incorporated 5BUdR and were killed by light, the sensitivity to light of cells containing 5BUdR substituted cellular DNA was measured. Cells were exposed to 5BUdR in the presence of serum so that 5BUdR would be incorporated into cellular DNA. These cells were infected either before or after the exposure to 5BUdR. The fraction of cells able to produce foci after exposure to light was measured (Fig. 2). The inactivation followed single hit kinetics with a resistant fraction of 1–2 per cent. In another experiment cells were exposed to 5BUdR and serum for 3 days preceding infection. The resistant fraction was reduced to less than 0·1 per cent. The resistant fraction represents those cells which did not incorporate 5BUdR. The inactivation measured is the result of cell killing. The initial slope of the cell killing curve is about twenty-fold greater than that for focus formation (Fig. 1). This difference in slope demonstrates that, when stationary cultures are used, the inactivation of focus formation is not a result of cell killing. In addition the difference in slope means that there is no significant stimulation of S-phase DNA synthesis by infection with avian sarcoma viruses. The stimulation of DNA synthesis which has been reported[17] is probably an early effect of cell conversion.

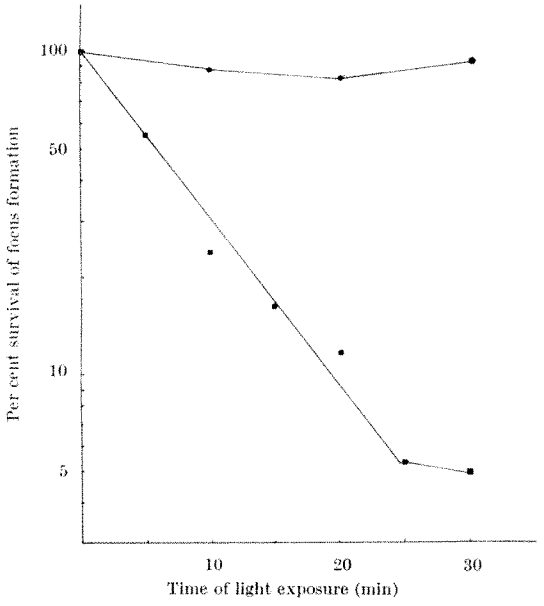

Fig. 1. Inactivation of focus formation by visible light. The protocol is explained in the text. Infection was carried out with about 8×10^4 f.f.u./culture of B77 virus and the cultures were overlaid with Eagle's medium with (■) or without (●) 5BUdR (5 μg/ml.). The cultures were exposed to light and replated on rat cells. In all cases, points represent the average of counts of duplicate cultures.

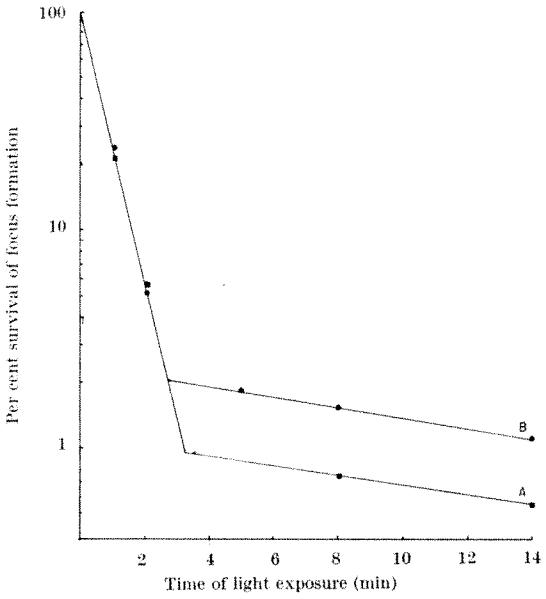

Fig. 2. The inactivation by visible light of the capacity of cells labelled with 5BUdR to produce foci. Cultures of stationary cells were either infected with 8×10^4 f.f.u. of B77 virus and incubated with 5 μg/ml. 5BUdR and 4 per cent foetal calf serum for 22 h (*A*), or incubated in the same medium and infected after incubation (*B*). The same protocol described in the methods section was followed from this point.

The difference between the second and third hypotheses is whether the new DNA is replicated from cellular DNA or whether it is transcribed from viral RNA. To distinguish between these possibilities, cultures of stationary chicken cells were infected at multiplicities of greater than 1 f.f.u./cell. If the new DNA is transcribed from viral genes, increasing the multiplicity of viral genes present in a cell might increase the number of copies of the new DNA; and the cell's focus-forming potential might be more resistant to light inactivation than that for a cell with a single copy of the new DNA. If the new DNA is cellular, the number of copies of the genes per cell would be independent of the multiplicity of infection, and the rate of focus inactivation by light would be the same at all multiplicities of infection. Parallel cultures of stationary chicken cells were infected with Schmidt–Ruppin virus at 3 f.f.u./cell or 0·15 f.f.u./cell in the presence of 5BUdR and exposed to light (Fig. 3). Focus production in cells infected at the higher multiplicity was more resistant to inactivation by light than it was for cells infected at the low multiplicity. Thus it seems that the new DNA is transcribed from viral genes.

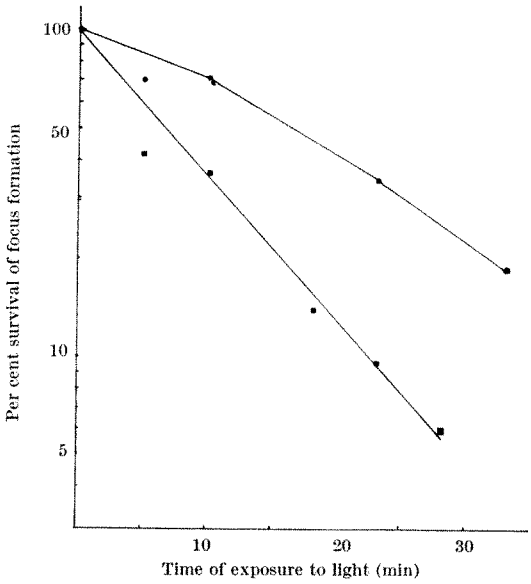

Fig. 3. The effect of multiplicity of infection on light sensitization caused by 5BUdR. Methods are described in the text. Cultures were infected with either 3 f.f.u./ml. (●) or 0·15 f.f.u./ml. (■) of the Schmidt-Ruppin virus and overlaid with medium containing 50 μg/ml. 5BUdR.

This experiment also serves as a further control for cell killing. If the light inactivation curves were the result of cell killing, increasing the multiplicity of infection should either increase the amount of cell killing or it should remain the same. But inactivation of focus formation is actually reduced by increasing the multiplicity of infection. This result is incompatible with the cell killing hypothesis.

The requirement for DNA synthesis early in infection of chicken cells by avian sarcoma viruses has been well documented[1,2,6]. There seem to be two parts to this requirement for DNA synthesis. In addition to the requirement for normal S-phase DNA synthesis and cell division[18], there is a requirement for non-S phase DNA synthesis. This non-S phase DNA synthesized following infection can be selectively labelled with 5BUdR using cultures of stationary cells. Subsequent exposure to visible light demonstrates that the non-S phase DNA required for focus formation is less sensitive to light than 5BUdR labelled S-phase DNA. The controls show that the inactivation of focus formation by light exposure is not the result of cell killing when the 5BUdR treatment is done in cultures of stationary cells.

The non-S phase DNA synthesis could involve the selective replication of cellular genes required for infection by avian sarcoma viruses, but the dependence of this non-S phase DNA synthesis on the multiplicity of infection makes this hypothesis less likely. Furthermore, because the DNA synthesized following infection by avian sarcoma viruses is specific for the viral strain used in the infection[6,19], a different set of cellular genes would be required for each strain of avian sarcoma virus.

These results are consistent with the model that the required S-phase DNA synthesized contains the genetic information for continued cell growth and division, and the required non-S phase DNA synthesized represents viral genetic information transcribed from viral RNA to a DNA intermediate.

Cultures and Irradiation

A modified Eagle's minimum essential medium (E) (obtained as a powder from Schwarz BioResearch, Orangeburg) was used. ET medium was made by adding 20 per cent tryptose phosphate broth (Difco Laboratories; Detroit, Michigan). The medium was supplemented with calf serum (Microbiological Associates) and/or foetal calf serum (Grand Island Biological Co.) as noted.

Primary cultures were made from 11–13 day old chicken embryos[20] (White Leghorn eggs were obtained from Sunnyside Hatchery, Oregon). Cultures containing $7{\cdot}5 \times 10^5$ cells were prepared in 60 mm Petri dishes (Falcon Plastics) in ET medium using cells from the first to fifth transfer generation. The medium was changed to fresh ET one day after preparation and the cultures were infected after 2 days of further incubation. Rat cell primary cultures were prepared from 12–14 day old embryos. Feeder cultures containing 5×10^5 cells were prepared in 60 mm Petri dishes in ET media supplemented with 4 per cent foetal calf serum.

B77 and Schmidt-Ruppin stocks have been described. High multiplicity of infection experiments used virus concentrated 100× by centrifugation[21]. Chicken cell cultures were exposed to 0·2 ml. virus, incubated for 40 min at 38° C, and overlaid with Eagle's medium containing 5BUdR (Calbiochem) or other analogues as indicated. After incubation for 18–22 h, the cultures were washed and overlaid with Tris buffered saline (0·14 M NaCl, 0·005 M KCl, 0·00033 M Na_2HPO_4, 0·025 M Tris, 0·0005 M $MgCl_2$, 0·001 M $CaCl_2$), exposed to the light source, resuspended with the aid of trypsin, diluted, and replated on previously prepared rat cell feeder cultures. 12–18 h later the medium was replaced with ET medium containing 0·6 per cent agar, 4 per cent calf serum and 4 per cent foetal calf serum. Foci were counted 6–8 days later. Counts on duplicate cultures differed by less than 20 per cent.

Cultures in Tris buffer were exposed from the underside at 6 cm distance to a light source consisting of two Westinghouse FS20 fluorescent sun lamps. This lamp emits a peak efficiency at 310 nm. Because irradiation from this source was found to cause considerable damage to the cells, filters consisting of 225 ml. tissue culture flasks (Falcon Plastics) filled with 0·3 mg/ml. thymidine (path length = 3 cm) were interposed. When this filter was used very little damage was observed to control cells which contained no 5BUdR.

Following incubation with ^{3}H-thymidine the cells were fixed with ethanol-acetic acid (3 : 1), washed with water, air-dried, coated with 'NTB3' nuclear track emulsion (Kodak) and exposed for 7 days at 4° C. The cultures were developed and stained with Harris's haematoxylin. For determination of 5BUdR incorporation into RNA, cells incubated in medium without serum containing 1 μCi of ^{3}H-5BUdR (Schwarz BioResearch, 10·6 Ci/mmole) were sonicated for 45 s and divided into two aliquots. Total incorporation was measured by precipitating twice with 1·5 per cent perchloric acid (PCA), resuspending in 0·3 M KOH and counting in 10 ml. of 'Scintisol' (Isolab). RNA incorporation was measured by precipitating with 1·5 per cent PCA + 100 μg bovine serum albumin, filtering on Whatman 'GF/A' filters, incubating at 37° C for 20 h in 0·3 M KOH, reprecipitating the supernatant with 1·5 per cent PCA and counting the remaining supernatant in 10 ml. of 'Scintisol'.

Theory for the Mechanism of Chloroquine Resistance in Rodent Malaria

The appearance of succinate dehydrogenase in the chloroquine resistant parasite suggests that resistance is acquired by a switch in the respiratory pathway to the citric acid cycle.

MITOCHONDRIA of the rodent malaria parasite *Plasmodium berghei berghei* undergo a metamorphosis in their morphology and physiology during the parasite life cycle[1]. This observation prompted us to consider whether the physiological lability of the parasite could play a part in its ability to develop resistance to chloroquine.

References to the action of chloroquine on plasmodial and other cells have been reviewed by Peters[2,3] and Aviado[4]. The literature indicates that chloroquine acts at all cell sites so far examined, by binding to RNA, DNA and cell membranes, by inhibiting hydrolytic and respiratory enzymes and by being concentrated in the lysosomes. In malarial therapy, however, it has been found that the drug is effective on the intraerythrocytic trophozoite stages but is ineffective against the exo-erythrocytic schizonts and the mosquito-borne sporogonic stages. We considered that, because chloroquine has been shown to bind to double-stranded bacterial DNA[5], to mammalian DNA and to polyadenylic and polyguanilic acids[6] and to inhibit DNA synthesis in plasmodia and bacteria[7,8], it is improbable that the DNA of the insensitive stages, or of chloroquine-resistant trophozoites of *P. berghei*, would be sufficiently different from that of the chloroquine-sensitive trophozoites to confer resistance. It has also been shown that chloroquine inhibits plasmodial hexokinase[9], but because the exo-erythrocytic schizont seems to be essentially similar to the erythrocytic trophozoite in its respiratory activity[1,10] and the former is insensitive to chloroquine we considered it unlikely that the inhibition of hexokinase is the primary action of chloroquine.

P. berghei and *P. knowlesi*[11] digest haemoglobin and several workers[12,13] have shown that the latter derives adequate supplies of most amino-acids from this source. *P. berghei*[14,15], *P. knowlesi*[16] and the avian malarias[17] ingest haemoglobin and degrade it in the phagosomes so formed. Chloroquine rapidly causes a clumping of the phagosomes (haemozoin vesicles) and later their expulsion from the parasite (reviewed by Peters[3]). Cessation of haemoglobin digestion must be related to the clumping and expulsion of the phagosomes and we therefore consider it likely that amino-acid starvation, resulting from the inhibition of haemoglobin degradation, is the primary means whereby chloroquine is effective against the trophozoite stages of the malarial parasites.

Chloroquine sensitive rodent plasmodia accumulate greater concentrations of the drug than chloroquine resistant parasites[18–20] and Macomber *et al.*[18] have suggested that chloroquine resistance may be based on an impairment of the mechanism by which the drug is accumulated. Fitch[20] has proposed that the major difference in the drug levels attained in sensitive and resistant parasites is "due to a decrease in the number, affinity or accessibility of chloroquine receptor sites" in the plasmodium. Our present observations suggest that these differences, though closely associated with the phenomenon of chloroquine resistance, are secondary to a more fundamental change in the parasite's physiology.

Because the trophozoites of chloroquine sensitive *P. berghei* lack a citric acid cycle[21,22] but the sporogonic stages may utilize this pathway[1] we postulated that chloroquine resistance in the trophozoite stages could be acquired by a simple switch to citric acid cycle activity and the synthesis of amino-acids by transamination of intermediates of this cycle.

As a preliminary step in examining this hypothesis we have investigated the occurrence of succinate dehydrogenase (SDH) in chloroquine sensitive and chloroquine resistant lines of *P. berghei*.

The lines of the parasite used in this study were the parent drug sensitive Keyberg 173 (N) strain and two others derived from it, the chloroquine resistant RC line[23] and the chloroquine resistant NS line[24]. The RC line differs from the N strain in being an obligate parasite of reticulocytes and in lacking haemozoin, whereas the NS line possesses haemozoin and, developing readily in normocytes, induces a rapidly fulminating infection similar to that of the parent N strain. The rodent hosts were *Eperythrozoon* and *Haemobartonella*-free, male TFW mice weighing about 20 g. SDH activity was located by the nitro-blue tetrazolium technique described by Pearse[25]. The following experiments were performed and repeated a minimum of ten times with each strain studied: (1) Blood-films were air-dried and unfixed; (2) blood films were quenched in acetone cooled in liquid nitrogen; (3) blood films were fixed for 5 min in 5 per cent formalin in 0·05 M phosphate buffer *p*H 7·4 at 0° C; and (4) heat denatured blood films were incubated in the following test and control media: (*a*) test medium; (*b*) medium lacking succinate; (*c*) medium containing 0·05 M sodium malonate; (*d*), (*e*) and (*f*) as (*a*), (*b*) and (*c*) respectively but containing $2{\cdot}5 \times 10^{-4}$ M phenazine methosulphate (PMS). Films were incubated for 30, 60 and 120 min at 37° C in air. In some experiments cryostat-cut sections of unfixed mouse liver were incorporated as positive controls. The ferricyanide technique of Kerpel-Fronius and Hagos[26] for the localization of SDH activity was unsuitable for the present study, for the ferricyanide was readily reduced by the mouse haemoglobin.

The results of experiments with the N strain confirmed those of Howells[1]. No demonstrable SDH activity could be observed in these parasites (Fig. 1). Following induction of reticulocytosis by administration of phenylhydrazine to mice and subsequent infection the enzyme activity in the reticulocytes was apparent as dots scattered through the cell and did not resemble the distribution observed in RC line infected reticulocytes. N strain parasites in reticulocytes were sensitive to chloroquine

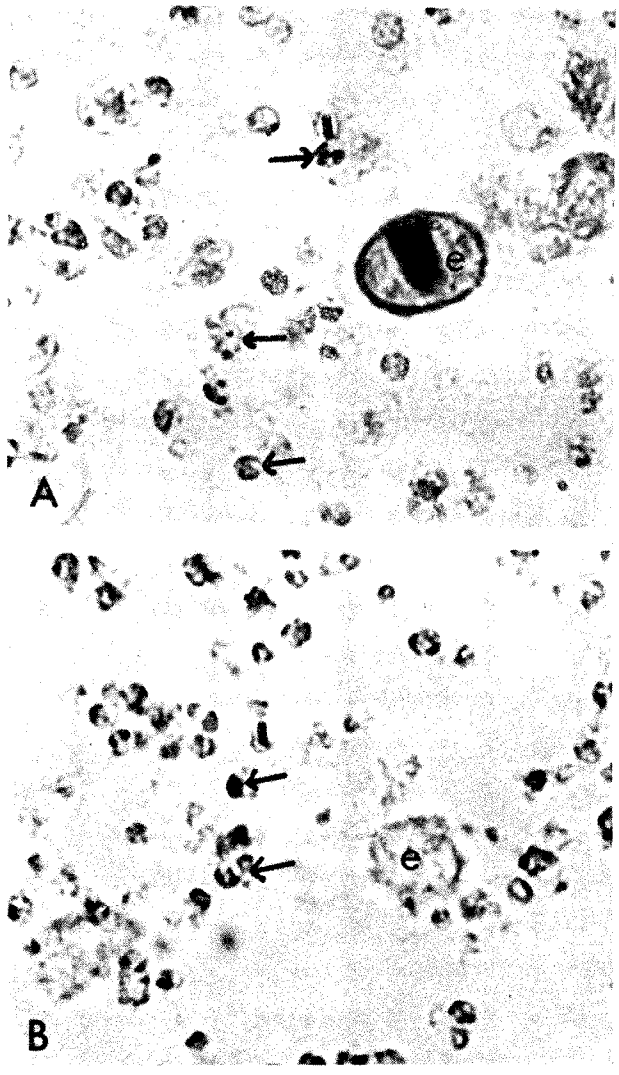

Fig. 1. Films of mouse blood infected with *P. b. berghei* N strain (×1,800). *A*, Film incubated in test medium for SDH determination. Note deposits of formazan in cytoplasm of leucocyte (e) and the dense appearance of the pigmented malarial trophozoites. In the preparation these parasites do not appear to contain a blue formazan deposit. *B*, Film incubated in test medium for SDH determination and sodium malonate. Note lack of formazan deposit in leucocyte. Trophozoites contain granules of pigment.

and did not possess SDH activity, even after chloroquine exposure.

Results with the RC line indicate that erythrocytic forms of the parasite possess a demonstrable SDH activity (Fig. 2). This activity, which was localized within the parasite, was malonate and heat sensitive and dependent on exogenous succinate. Unfixed, air-dried blood films gave a strong activity but a considerable loss of cells occurred from such slides during incubation. Fixing the films in acetone at room temperature caused a loss of enzyme activity, possibly intensified by loss of coenzyme Q from the tissues[27], but enzyme activity was preserved by quenching in cold acetone. This technique also prevented cell loss. SDH activity was located most accurately by the formalin fixed slides because little or no non-specific absorption of formazan to cell membranes occurred in these preparations.

Initial experiments on 5 day old infections of the NS line in undrugged mice indicated that the pigmented, normocyte dwelling parasites lacked SDH activity. Further tests on 18 to 21 day old infections in undrugged mice gave positive results. At this stage of the infection the parasites were apigmented and occurred in reticulocytes. The effect of chloroquine on the development of the parasitaemia in the NS line was investigated by Peters *et al.*[24]. These authors demonstrated that though the parasites invade normocytes during the early stages of

Fig. 2. Films of mouse blood infected with *P. b. berghei* RC line (×1,800). *A* and *B*, Film incubated in test medium for SDH determination. Note deposits of formazan in leucocyte (e) and in the malarial trophozoites (arrows). *C*, Film incubated in test medium for SDH determination and sodium malonate. Note absence of pigment and formazan from these para sites (arrows).

infection in undrugged mice, if chloroquine is administered to mice at the time of infection the parasites invade immature red cells for the first few days, but later invade normocytes. The SDH activity of parasites in drugged mice was therefore investigated. Parasites maintained under drug pressure from day zero possess SDH activity but are restricted to reticulocytes and lack pigment. If the parasitaemia is allowed to develop without chloroquine and the drug administered on day 4 (Fig. 3), within 24 h a 60 per cent mortality occurs and pigmented, normocyte dwelling parasites are largely lost from the circulation. The surviving parasites possess SDH activity. Within 3–4 days after the chloroquine dose some parasites again do not possess SDH activity. Further drugging induces a further switch to SDH activity. It is significant that administration of chloroquine on day 4 does not reduce the number of parasites in reticulocytes. The habitation of reticulocytes, however, does not itself confer resistance to the parasites, for drugging of the parasites on day 9 causes a significant (approximately 30 per cent) mortality of reticulocyte parasites. Exposure of a population of N strain parasites within reticulocytes to chloroquine for 24 h does not induce SDH activity nor are such parasites resistant to the drug.

These simple experiments demonstrate a significant difference between the chloroquine sensitive and chloroquine resistant strains of *P. b. berghei*. The key role of SDH in the citric acid cycle, and the improbability that this enzyme represents the only difference between the chloroquine-sensitive and resistant strains, indicates that a considerable difference occurs in their respiratory pathways. These results also indicate that, although the RC and NS lines appear to be morphologically distinct variants in undrugged mice, under drug pressure both have a similar appearance and, in possessing SDH activity, presumably possess a common mechanism of chloroquine resistance. We therefore consider that the physiologically labile NS line represents an intermediate stage between the parent N strain in which the trophozoites catabolize glucose by glycolysis[28] and the RC line in which all trophozoites possess SDH activity and presumably catabolize glucose aerobically.

In older infections of the NS line the trophozoites develop SDH activity even in the absence of the drug. Such a change might be induced by the immune response of the mouse. The occurrence of the enzyme in the sporogonic stages of drug sensitive *P. berghei*[1] further indicates that the enzyme does not appear *de novo* in the chloroquine resistant organisms but that its appearance may be related to the respiratory switch which, in sensitive parasites, occurs only in association with gametocytogenesis. This may explain why the N strain, which had lost the ability to produce gametocytes during twenty years of syringe passage in the laboratory, on repeated treatment with chloroquine not only developed resistance but also began to produce gametocytes[24]. It may also relate to the enigmatic observation of Ramkaran and Peters[29] that the infectivity of a chloroquine resistant line of *P. berghei* to *Anopheles stephensi* was enhanced by chloroquine.

We consider that the presence of SDH in the chloroquine resistant parasites indicates a respiratory difference between the sensitive and resistant strains of *P. berghei*. The lability of the NS line and induction of SDH activity by chloroquine further suggests that the utilization by the parasites of the respiratory pathway involving SDH is not simply an incidental factor but is in some manner directly associated with chloroquine resistance.

The avian malarias present an apparent obstacle to this hypothesis in that they utilize the citric acid cycle, synthesize amino-acids by transamination[28], but still produce pigment and are sensitive to chloroquine[2,30]. There is a widely held belief that chloroquine resistance cannot develop in avian malarias. This, however, has been disproved by the study of chloroquine resistance in

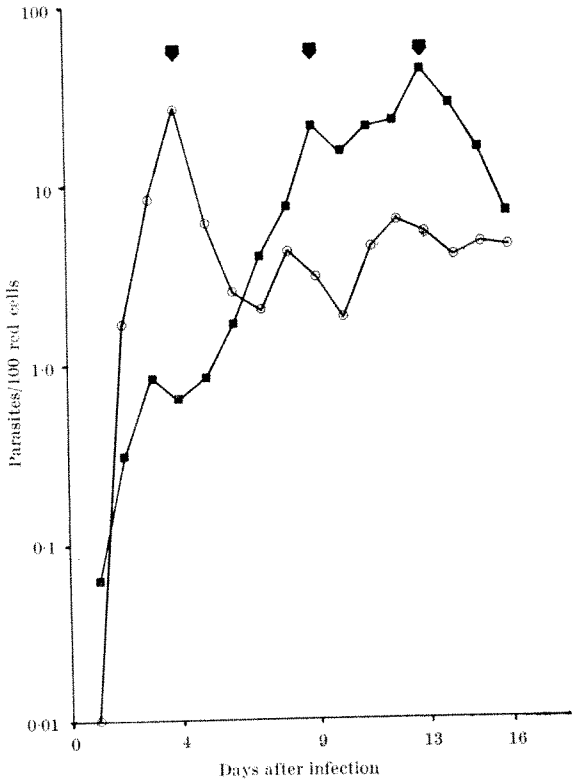

Fig. 3. The course of parasitaemia in mature and immature erythrocytes in mice infected with the NS line of *P. b. berghei* treated with chloroquine. Arrows indicate days on which chloroquine was administered (100 mg/kg subcutaneously). Note rapid decline in the number of normocyte parasites after dosing with chloroquine on day 4. ○—○, Parasites in normocytes; ■—■, parasites in reticulocytes.

P. gallinaceum[31]. Pyridoxine, the precursor of pyridoxal phosphate, an essential cofactor in many transamination reactions, does not inhibit the effect of chloroquine and mepacrine on *P. berghei* N strain (R. E. H. and D. C. W., in preparation). But pyridoxine does inhibit the effect of mepacrine (and quinine) on the avian parasite *P. lophurae*[32]. (Mepacrine and quinine resistant strains of *P. berghei* show cross resistance to chloroquine[33,34]. Observations in this laboratory indicate that there is a common mechanism of resistance to mepacrine and chloroquine.) *P. lophurae* has been shown to be dependent on its host cell for coenzyme A (refs. 35, 36). Similarly it may be that the amount of host cell pyridoxine limits the amount of transamination which avian parasites may perform and is a controlling factor in the response of the parasites to chloroquine.

The results presented indicate that the chloroquine resistant line of *P. berghei* differs from the sensitive strain in utilizing the citric acid cycle. Further work is in progress on the respiratory processes of these strains. An immediate objective is the fine structural location of the SDH activity. The transamination of Krebs cycle intermediates by the parasites is being investigated.

These studies were supported in part by the World Health Organization, the Medical Research Council and the US Army Research and Development Command.

Amnesic Syndrome: Consolidation or Retrieval?

by
ELIZABETH K. WARRINGTON
L. WEISKRANTZ*
The National Hospital,
Queen Square,
London

Amnesic patients can remember verbal material if they are tested with a method of partial information. The present experiments show that such retention depends more on the method of retrieval than on the method of acquisition. It is suggested here that long-term memory can be demonstrated in the patients if methods are used that eliminate incorrect and interfering responses.

Amnesic subjects are not so forgetful as was once thought. Learning and retention of motor skills such as rotary-pursuit tasks and tracking tasks were possible if not altogether normal in one severely amnesic subject[1]. Perhaps more strikingly, amnesics can learn to recognize a series of fragmented pictures and words and show evidence of retention over days and even weeks[2,3]. Moreover, the principle of providing partial information as a stimulus for retrieval has been shown to operate for verbal as well as perceptual stimulus material[4]. Why, then, do amnesic subjects learn and retain verbal material using this method when the same items are relatively unavailable using conventional methods? Is such retention by amnesics made possible by their having learned the material in a particular form, or by being presented with material in that form at the retention stage? Moreover, is it merely a favourable retrieval technique for all subjects, amnesics and controls alike, or is there a special factor which disproportionately affects the amnesics' performance?

The aim of this experiment was to manipulate independently both method of learning and method of retrieval. The results suggest that in amnesic subjects the retrieval procedure is more relevant than the method of learning and that the method of retrieval itself is critical in determining their performance on tasks of retention. The effectiveness of partial information in eliciting stored items of information raises various theoretical questions and allows one to relate the human amnesic syndrome to the relevant animal experiments.

Four patients with severe amnesic states, one following a temporal lobectomy and three with alcoholic Korsakoff psychosis (Nos. 1, 2, 5 and 6 reported in a previous study[3]), were available for these experiments. They had normal intellectual capacities other than memory defect. There were fourteen control patients with extra-cerebral neurological disease who took part in these experiments, six in experiment 1 and eight in experiment 2. No control subject did both experiments. These control subjects were tested in two subtests of the Wechsler Adult Intelligence Scale (WAIS) (Vocabulary and Block Design) and were matched as closely as possible for age and intellectual level with the amnesic group.

In the first experiment the learning conditions (using the fragmented word technique, see Fig. 1) were kept constant, and subsequent retention was measured using three different retrieval methods: recall, recognition and one partial information technique (fragmented words). Because amnesic subjects can learn by this method, the three retrieval methods may be directly compared.

Three lists of nine words, all of high frequency, were drawn from the Thorndike–Lorge word count. Two

Fig. 1. Example of fragmented word.

* Present address: Department of Experimental Psychology, University of Oxford.

fragmented versions of each word were prepared as described previously[3]. On each learning trial the most incomplete version of the word was presented first, then the less incomplete version followed by the complete word, and so on through the list of nine words. Subjects identified each word as soon as possible. The error score was defined as the number of additional versions (other than the most fragmented version) required for identification. Five learning trials plus a retention test were given on each of the three lists.

There were three retention conditions, each being attempted by all subjects in a counterbalanced order. Retention was assessed 1 min after each learning task was completed; the interval was filled by counting backwards from 100. There was an unfilled interval of 5 min between each condition. (1) Recall: the subject gave a spoken report of words from the test list. (2) Recognition: the subject was required to respond "Yes" or "No" sequentially at self-paced rate to each of eighteen words (printed in the same size and type of lettering as the stimulus list), nine new words and the nine old arranged in a random order. (3) Partial information: a further sixth trial using the method of fragmented words was given. The mean error score for each group in experiment I on the five learning trials for all lists combined is shown in Table 1. The score on trial 1 is an indication of the perceptual difficulty of the task before any further memory component has been introduced. The word lists for each condition were of approximately equal difficulty and it can be seen that the controls were reasonably well matched with the amnesics on the perceptual measure.

The retention scores (expressed as percentage correct) for each method of retrieval are given in Table 2. The recognition score was calculated by subtracting the number of false-positive errors from the number of items from the stimulus list correctly identified. The fragmented word retention score is expressed in terms of a savings measure between the fifth and sixth trials.

Though the amnesic group learned nearly as efficiently as the control group (Table 1), there was a clear-cut deficit on retention, both by recall and by recognition, in the amnesic group ($P < 0.002$ and 0·01 respectively). Neither group showed any significant degree of decrement on retention by partial information. As there was a ceiling effect in the control group with the recognition procedure, it is not clear from these findings whether or not retention elicited by partial information is differentially affected in amnesic subjects. It is clear, nevertheless, that learning the material with the partial information technique does not make the information normally available to recall and recognition by amnesics.

In the second experiment different methods of retrieval were again used to assess retention after a constant learning condition, but in this case a conventional word learning task (reading a word list three times) was followed by one of four retention conditions. It is known that retention of such material measured by recall and recognition in amnesics is very poor[5]. The question is whether material originally presented in this conventional manner can be shown to be retained using methods of partial information.

Lists of eight five-letter words, all of high frequency in the Thorndike–Lorge count, were used as test stimuli. Subjects were given three learning trials followed by a retention test. There were four retention conditions and each subject learned three lists for each retention condition. A learning trial consisted of reading aloud a list of eight whole words (printed in large black capital letters on white cards) presented at a two-second rate. Retention was assessed in all subjects (after a 1 min delay filled with counting backwards) by each of the following methods in a counterbalanced order: (1) recall; (2) recognition; (3) partial information—fragmented words; (4) partial information—initial letters of words. The procedure for the first three retrieval conditions was the same as described for experiment 1; in condition (4) the first three letters of each word were presented and the subject required to identify the stimulus word. For each retention condition there were no inter-list intervals, though between each retention condition there was a 5 min unfilled interval.

A preliminary task preceded the preparation of the word lists for the two retrieval methods using partial information. First, subjects were shown fragmented words (20 per cent patterned) used in method 3, and any word which could be identified in this incomplete version was rejected from the test list. Each test list for each individual subject was made up of eight words which thus could not be read in the fragmented form. Second, the subjects were shown the first three letters used in method 4 and asked to think of a five-letter word. The final lists were constructed individually for each subject using only words which were not responses in the guessing task.

Mean retention scores for each of the four methods of retrieval for each subject group are given in Table 3. An analysis of variance was computed using arcsine transforms of the mean retention scores for subject groups and retention conditions. With conventional methods of assessing retention (see Table 3), that is, by recall and by recognition, the amnesics were significantly worse than the controls ($P < 0.02$ and < 0.001 respectively by the one-tailed t-test; the differences were also significant by the Mann–Whitney U test, $P < 0.02$ in both cases). No significant difference between subject groups was found for either of the methods of partial information (see Table 3) and in neither case could a ceiling effect account for the similar level of performance in the two groups. Although the overall difference between the amnesic and control group was not significant, the difference between retention conditions was significant ($P < 0.001$). Furthermore, the group x retention conditions interaction term was significant ($P < 0.05$) indicating that the retention conditions had a differential effect on the amnesics and the control groups. Retrieval by recognition was superior to retrieval by recall in the control group ($P < 0.0001$) but not in the amnesic group, while retrieval by partial information was superior to retrieval by recall in the amnesic group ($P < 0.05$) but not in the control group.

Table 1. MEAN ERROR SCORE ON LEARNING AND RETENTION TRIALS

	Trial No. 1	2	3	4	5	6
Amnesic group N = 4	6·0	2·9	1·8	2·1	1·4	1·5
Control group N = 6	7·9	3·0	1·7	1·1	0·7	0·8

Table 2. RETENTION SCORES—EXPERIMENT I

	Controls	Amnesics
Recall	48 per cent	14 per cent
Recognition	94 per cent	59 per cent
Fragmented words	96 per cent	94 per cent

Table 3. RETENTION SCORES—EXPERIMENT II

	Controls N = 8	Amnesics N = 4
Recall	13·0	8·0
Recognition	18·7	10·5
Fragmented words	11·1	11·5
Initial letters	16·0	14·5

It can be seen that the method of learning did not differentially affect retention in amnesic subjects, in contrast to the method of retrieval, which did. The fact that information in long-term memory is available even after learning by conventional methods, if a particular retrieval method is used, is further evidence that it is inappropriate to characterize the amnesic syndrome as being a failure of registration or consolidation. We have shown previously that the normal relationship between recall and recognition may not be valid for amnesics; there was a relatively greater deficit on the recognition task than the recall task in the amnesic group[6]. The present experiment is consistent with this finding and furthermore has shown that retention by partial informa-

tion is a particularly favourable retrieval method for the amnesics but not the controls.

It is paradoxical that partial information in the form of fragmented letters or the initial letters of the word should be a more effective retrieval method than a conventional "yes–no" recognition task where the whole word is presented. The paradox can be resolved if one considers the proposition that to store or retrieve too much is as disastrous as to store or retrieve too little for efficient and effective memory. One special property of retrieval by partial information is that the subject can eliminate incorrect false-positive responses. The number of alternatives which would match the fragmented words must be very limited if not unique and in the case of the parts of words the number of alternatives is finite and can be counted. It has already been shown that the number of alternatives that could be formed from the same first three letters is a significant variable for both amnesic and control subjects[4]. This possibility of rejecting incorrect responses would be evident if either long-term memory information were not appropriately categorized or if there were too many items of stored information. It has been shown that organizational processes are important in normal memory[7,8] and it can be shown that at least some classification processes are possible for amnesics. It is therefore suggested that in the amnesic syndrome information in storage is either not inhibited or not dissipated in a normal fashion. This would account for the observations of a high incidence of prior list intrusions in amnesic subjects in tests of recall[6,10,11]. Performance on recognition tasks is subject to proactive interference effects, and it has been shown that there is a very rapid build-up of proactive interference in a continuous recognition memory task[12], which might account for the fact that recognition is no more favourable a measure of retention than recall in the amnesic group. It may not be too far-fetched to suggest that effective normal day-to-day memory demands that previous events be forgotten or suppressed and the inability to do so in the amnesic subject produces responses analogous to prior-list intrusions recorded in formal verbal learning experiments. From this point of view normal forgetting may be a positive benefit for efficient memory.

We now have two types of task, motor learning and retention by partial information, which are relatively well preserved in amnesic subjects. Is there a common factor linking performance on these apparently dissimilar tasks? Learning of new motor skills in normal subjects is not necessarily rapid, but retention over long periods of time is good. One property of motor skills is that retention is remarkably unaffected by interference effects in general[13] and by proactive interference in particular[14]. It is therefore suggested that both types of task, not necessarily for the same reason, are resistant to proactive interference.

Hitherto there has been an apparent discrepancy between amnesic deficits in man, as judged clinically, and the results of animal experiments that have attempted to generate amnesia in the laboratory. The present interpretation, based on disinhibition and interference phenomena rather than on faulty consolidation, allows one to bring the human amnesic syndrome, in which the hippocampus has been implicated[5], directly into line with the results of experimental medial–temporal and hippocampal damage in animals. For example, hippocampectomized rats and monkeys are slower to extinguish, slower in discrimination reversal tasks and under-react to novel stimuli when performing strongly established responses. Kimble[15] suggests that a failure of internal inhibition, Douglas and Pribram[16] that a failure of dissipation of awareness of unrewarded events would account for these findings. No doubt the cognitive capacities of man are different, and the defect would therefore have a different manifestation, but it is possible that the underlying functional disorder is the same.

We thank Dr R. T. C. Pratt for providing facilities to carry out this work and Dr A. D. Baddeley for his comments on the manuscript. Support was received from the MRC.

Experimental Production of Transients in Human Interaction

by
ELIOT D. CHAPPLE
Research Center,
Rockland State Hospital,
Orangeburg, NY 10962

A review of some methods for measuring aspects of human interaction, based on the rhythmic patterns of activity and inactivity which two people display when they meet.

In the measurement of interaction, the beginnings and endings of actions are operationally defined by observing the associated contractions and relaxations of muscle systems (in the human, chiefly those of the face and head, often associated with sound and usually coincident with movements of the mouth). The actions are, in effect, made up of the fixed action patterns of the animal[1]. With the criteria of contraction and relaxation, the flow of fixed action patterns can be broken into separable "action" units; this procedure contrasts with much ethological description. Durations, as well as frequencies, thus become available for quantitative analysis.

The sequence of measurements demonstrates that their regularities are rhythmic in character. Though these rhythms are the fundamental property of the actions (and inactions) of humans and other animals, uniformities are obscured by environmental factors, particularly by the interference of the rhythms of other individuals. If individual rhythms are not completely synchronized, transients are set in motion. One can, however, define the experimental conditions through which a perfectly synchronized or "free-running" state can be achieved, in a first approximation at least, as being parallel to such states in the circadian rhythms[2,3].

Components (Variables) of the Interaction Sequences

Only two-person interaction will be considered here. Given two persons, A and B, only four states are possible: (1) A acting, B inactive; (2) A inactive, B acting; (3) A and B both acting; and (4) A and B both inactive. Because these states occur in sequences, one can then define and differentiate sequences by their components; in effect, one determines the order of the transition states and whether A or B is responsible for their appearance. By definition, any given sequence is begun and ended when the two individuals assume opposite states.

The free-running state may be a natural consequence of the complementarity of the two individuals' basic rhythms, or deliberately contrived by programming one individual's pattern to be the converse of the other's. In free-running, the rhythms show minimal variance. If one assumes that the pulses (the beats or tempos) are approximately equal, and the durations of the component actions and inactions are the quantitative alternates, then A and B will never interrupt each other or fail to respond. Runs of such synchronized interaction occur with partners of long standing—old friends or spouses[4]; they are extremely uncommon (and very brief) in the world of those with emotional disorders[5].

Interactional Asynchrony as Stress

In everyday human interaction, asynchrony is predominant, varying widely in its quantitative values. By hypothesis, each instance of asynchrony is regarded as an interactional stress, the stress being defined and differentiated by the components of the pattern (sequence) involved. One might argue that a brief non-response or interruption (or other sequential pattern) hardly has the dramatic implications which are ordinarily applied to the term "stress"; yet observation demonstrates that very small amounts of asynchrony can be sufficient in some people to trigger off a violent and sustained pattern of "acting-out". For many others, thresholds for very brief and irregular patterns of asynchrony are high enough for no appreciable disturbance of the rhythms to be demonstrable. Moreover, it should be emphasized that the threshold for each pattern of stress is usually different. Although one stress pattern leaves the subject "unruffled", another can quickly bring about substantial changes in his basal rhythms.

Thus stress, as here used, has no connotations of magnitude or intensity. It simply means that a particular type of asynchrony has occurred with specific quantitative properties in an interactional sequence; the stress may be repeated with the same or different durations, interspersed with other types of stress and with intervals of synchronization. When such a single stress is imposed on a basal rhythm, there may or may not be evidence of distortions of the rhythm; once ended, shifts in the interaction rate may or may not be evident. Obviously the constant repetition of such stresses—the mother not responding to the child, the wife constantly dominating the husband—brings about severe reactions, outbursts of temper, violence or withdrawal.

The quantitative properties of the various patterns of asynchronous interaction can be investigated by programming the interaction of the experimenter (the interviewer, B) in the durations of each component and the frequency of their repetition (and sequential position). This includes intervals of synchrony and the asynchronous sequences of stress experimentally introduced. Further, content is rigorously non-directive; intensity, pitch, timbre and articulation of the voice are held within narrow limits, as are their expressive movement cognates. The synchronous state is the first stage of the interview, and establishes the basal rhythm. A period of synchrony, following the period of stress, provides a "recovery" period. This then becomes the means through which the type, severity and extent of the stress and its transients are determined.

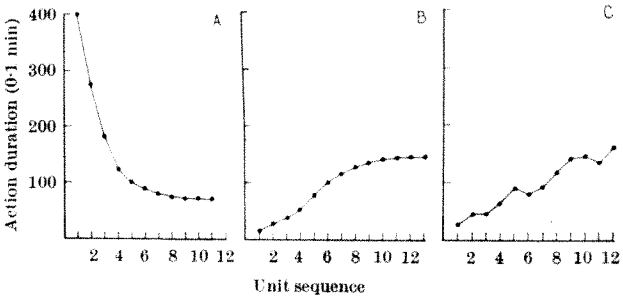

Fig. 1. Non-linear patterns of transients.

Initial State Transients

Interaction measurements seem best described as coupled relaxation oscillators[6]. Even though one expects the starting up of an oscillator to involve a transient state, this is very definitely the case when two oscillators (the two people) are coupled in the interaction sequence. These initial state transients are themselves worthy of comment, because they are so fraught with the emotional concomitants of entering a new situation, meeting a new person, or even shifting gears from one interpersonal relationship to another.

Thus, either person, or both, may be shy, bashful, pompous or pretentious. To "translate" these references to subjective (emotional) states and the behaviour which validates them, one has to trace the sequence of interaction patterns shown when interaction begins. One then observes a remarkable regularity in the quantitative values of the interaction measurements; a sequential shift in values (idiosyncratic but replicable) which underlines the variegated elements such as shyness or pretentiousness.

To a large degree, these can be defined as functions of the action and inaction variables. Thus, for example, if one plots the durations against their sequential order, it is common to find the values of the transients arrayed in a positive or negative non-linear function, as Fig. 1 indicates (for action durations).

Not all individuals, of course, show transients with any sequential frequency. They attain their basal level at the first or second action duration and remain there, though they usually exhibit a regular variation in durations with a rhythmic form, to be commented on shortly. These rhythmic variations may also modify the exponential form of the transients illustrated in Figs. 1*A* and *B*, as *C* demonstrates. But, further, in severely hostile individuals or those who are depressed the action durations may be extremely short, their variation being only a function of the low numbers themselves (a deviation from 3 to 5 s, for example).

The inactions (silences, if the term can include the absence of non-verbal responses) show similar transient properties. These are complicated by significant deviations in the initiative and dominance variables. Asynchrony may occur either by latency of response or by interruptive actions. It is ended when one or the other re-establishes synchrony, either by ending the mutual silence and initiating an action, or by persisting against the opposing action until the other falls silent.

Because human subjects can react with intense emotional severity to the introduction of the forcing oscillation (*Zeitgeber*), only threshold amounts (in durations and frequencies) are used. It is hypothesized that true entrainment and the appearance of a new synchronized endogenous oscillation in the individual are a function of a sustained and continuously repeated imposition of the forcing oscillation over long periods of time[1]. In re-establishing what seem to be basal levels, several months of exposure to forcing oscillations are usually required[7].

The criteria for determining the manifestations of the basal rhythm (the free-running period) of the individual

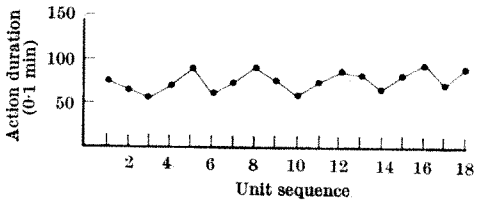

Fig. 2. Periodicity in sequential values of action duration.

are more complicated than those in circadian studies of activity, because the number of interaction variables is larger. Frequency, ratio of action duration to inaction duration and total amount of activity are present, but the endogenous impact of the initiative and dominance variables (analogous to what Wever calls the "special behaviour rhythms", as with an animal deciding to go on to a running wheel) also have to be taken into account[1]. They have their own periodicities: for example, the occurrence of asynchrony when B, the experimenter, does not respond builds up internal "pressures" to initiate and bring the silence to an end, which can bias the values of the basic variables.

As a consequence, a necessary further condition for evidence of the free-running period is the absence of asynchronous patterns of interaction on the part of A, the subject. Such patterns do not merely indicate the presence of biasing variables with their own periodic properties; they are also evidence of fixed emotional states which, by assumption and empirical evidence, seem to be the resultant of prior entrainment to a pathological oscillatory rhythm.

When they have achieved their base, most people show, as the figures indicate, a minor but regular variation; so much so that, after plotting the durations as in Fig. 1, the sequential values follow an apparent periodic curve (Fig. 2). For reasons described elsewhere, this internal rhythm within the duration sequence seems to be a function of variations in the intensity (amplitude) of the sound or expressive movements of the non-verbal response[1,6].

Experimental Stress

With the exception of the stress provided by the coming together of two people and the starting up and coupling of their oscillators, stresses are experimentally introduced only after the free-running oscillation is established (or its pathological form in the psychiatric states). The quantitative properties of the *Zeitgebers* used can be varied almost infinitely. Essentially, however, the sequential patterns involve either the initiative (latency) or dominance (interruption) variables.

In either category, one can vary the number of sequential trials, the duration of action or silence of A before B acts (initiates or interrupts), the length of B's action when initiating or persisting against A's opposition and, in the case of dominance, how long he continues after winning the competition for control. Further, in the event that a single programme sequence has been completed but A remains in his prior state, either being mute or continuing to talk, one can vary the interval before the sequence is repeated. Permutations within each of these categories of variables are manifold; further complications can be introduced if switching from one category to the other is programmed (as in ordinary free interaction give-and-take).

Figs. 3 and 4 illustrate two such experiments, for initiative and dominance respectively. Only enough of the basal rhythm is given to indicate its values and, in both, the same number of asynchronous patterns is used to make up the sequence. These experiments were conducted on the same day with the same individual, but not consecutively, to avoid carry-over of the transient reaction. Clearly the transients shown here have a very different quantitative form. It is important to emphasize that extreme reactivity to one type of stress does not mean that it will occur after a different stress pattern; neither does it follow that a positive slope for one will mean a positive slope in all transients.

Fig. 5 illustrates what happens to three persons with approximately equivalent basal rhythms when the same stress sequence given to the individual in Fig. 4 is administered. The subject of Fig. 5*A* is clearly "unflappable", at least to this amount of asynchrony. Though his values shift during entrainment, afterwards he returns immediately to his base. The subject of Fig. 5*B* is disturbed chiefly in his basal rhythms, with relatively small distortions of his other variables; that of Fig. 5*C* reacts so severely that the interview had to be ended before any significant shift took place.

Autonomic–Somatic Interdependence

In considering the numerical values it should be remembered that these interactional changes are not some kind of abstract aberration of the skeletal muscles—they are the behavioural manifestations of the autonomic–somatic system[1]. The nature of the forced oscillation (the stress) imposed on the system sets in motion, by hypothesis, specific (and idiosyncratic) autonomic changes. These provide the parametric values by which the severity and length of the reaction are determined. In relatively primitive investigations, pronounced changes in interactional rhythms have been reported after injections of adrenaline or acetylcholine (Mecholyl)[8]. Modern studies of emotion in physiology and biochemistry have made clear the fine tuning of the reaction patterns even if, surprisingly, little sophisticated measurement has been used[9].

As a consequence, in fear or anger or love, and all their variants (semantically and operationally), the measured interaction patterns change and can be identified together with concomitant physiological changes. These physiological changes involve both neurological and biochemical activators and combinations thereof, and have different temporal properties.

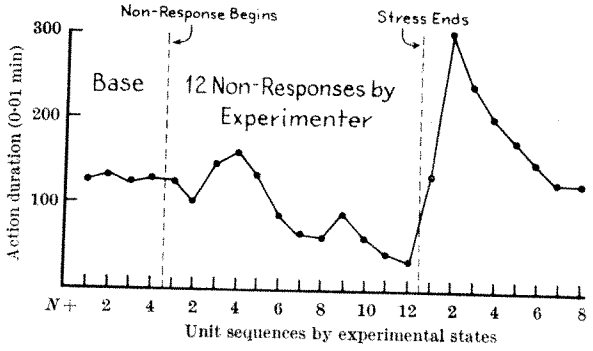

Fig. 3. Results of interaction experiment for initiative.

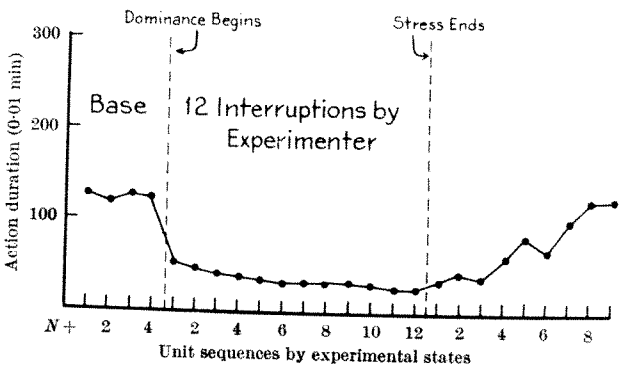

Fig. 4. Results of interaction experiment for dominance.

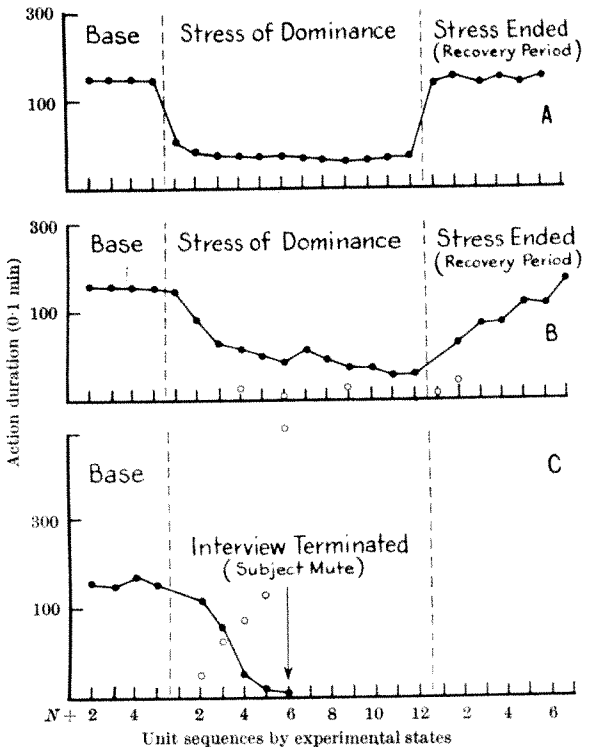

Fig. 5. Three different reactions to the stress sequence applied to the subject of Fig. 4. ●, Action duration; ○, latency.

As Fig. 5 illustrates, the transients are made up not merely of the action–inaction durations themselves but of the asynchronous initiative and dominance variables, those characteristic patternings of latencies of response and of the interruptions when one person breaks in on the other's action interval and begins to act himself. These variables are not merely elements or artefacts of oscillatory shifts; they are the stresses (for the other person) and the additional evidence of disfunctioning of the autonomic nervous system.

Thus basic shifts in the action-silence rhythms occur when a *Zeitgeber* is set in motion. They continue even after the entrainment sequence ends, but they are transformed in their emotional impact by the inability of the individual to manage to adjust, to synchronize, to avoid being disturbed and to be disturbing to those others with whom he comes in contact. Hostility, aggression, depression, in their interactional patterns, are thus compounded of the disturbances to the basal rhythms and the latencies or competitive actions of the asynchronous states. These variables are then variations of the primary oscillatory sequence; they serve to differentiate the transient reactions even further.

If one bears in mind the significance of transient multiplication when entrainment begins and the carry-over which may continue after the *Zeitgeber* is removed, then the emotional–interactional combinations which make up the many transients so far identified can be understood. If a transient appears after a stress situation is ended, its properties are varied emotionally (internally) by the prior transient manifested when the forced oscillation was imposed on the individual's basal rhythm. The mathematical formulation of two transients may thus be equivalent, but there is a carry-over from one transient which sets off the next, a kind of hysteresis which alters the nature and properties of the subsequent reaction.

Thus the magnitude of each transient, and the length of time it lasts, is a function of the magnitude of the forced oscillation and the duration of the entrainment period. In addition, the idiosyncratic differences in threshold and reactivity have to be borne in mind; these are the boundary conditions within which transients have their effects.

Increased Frequency of Deletions in DNA Polymerase Mutants of *Escherichia coli*

by

M. B. COUKELL
C. YANOFSKY

Department of Biological Sciences, Stanford University, Stanford, California 94305

Mutants of *E. coli*, deficient in DNA polymerase activity *in vitro*, spontaneously generate chromosomal deletions at a high frequency. Such deletions may arise from the inability of these strains to repair single-strand breaks in DNA efficiently.

SPONTANEOUS deletion of genetic material could involve one or more of the enzymatic processes in DNA repair, replication or recombination. We have determined the frequency of appearance of deletions in different types of *E. coli* mutants which are defective in the repair of damage to DNA resulting from ultraviolet irradiation. Mutations in a DNA polymerase structural gene(s) markedly increased the frequency of occurrence of deletions. The average frequency of spontaneously occurring *tonB* and *tonB-trp* deletion mutants in stationary phase cultures was determined as described in Table 1. The ultraviolet-sensitive strains examined and the frequency of *tonB-trp* deletions in each are listed in Table 1, experiment (*a*). Our previous studies[1,2] have indicated that even in closely related strains, differences in the structure of the chromosome in the vicinity of the *trp* operon can influence the frequency of *tonB-trp* deletions. The deletion frequency of each ultraviolet-sensitive strain was

therefore compared directly with its ultraviolet-resistant parent. Of the ultraviolet-sensitive strains examined, only strain P3478(W3110), which carries the *polA1* mutation[3,4], exhibited a *tonB-trp* deletion frequency significantly different from its parent. To determine whether the apparent increase in deletion frequency in strain P3478 was related to the presence of the *polA1* mutation, Pol$^+$ revertants of P3478 were isolated by selecting for resistance to methylmethanesulphonate (MMS)[3]. When the *tonB-trp* deletion frequency of several of these revertants was determined, we found that deletion frequencies were now similar to the low frequency characteristic of the W3110 parent. Values for one Pol$^+$ revertant (PR3478) are shown in Table 1, experiment (*a*). This revertant was used as a Pol$^+$ control in subsequent experiments. The magnitude of the increase in frequency of *tonB-trp* deletions in the *polA1* strain, relative to the Pol$^+$ revertant, varied between fifteen and forty-fold in separate experiments. The factors responsible for this variation are unknown. Thy$^+$ transductants of P3478 produced deletions at the increased frequency.

produced *tonB-trp* deletions at a frequency at least twenty-fold higher than the average frequency of the Pol$^+$ strains.

The *polA1* mutation causes no gross alteration in the position of the endpoints of *tonB-trp* deletions in the *trp* operon. The percentages of deletions terminating in genes *trpA*, *trpB*, *trpC*, *trpD* and *trpE* (or beyond the *trp* operon) of the parental strain (W3110 Thy$^-$) were 11, 23, 8, 8 and 50 per cent, respectively (35 deletions examined). For strain P3478 the percentages were 9, 22, 22, 7 and 40 per cent, respectively (45 deletions examined), and for strain PR3478 they were 7, 24, 20, 25 and 24 per cent, respectively (51 deletions examined).

PolA1 is an amber mutant which responds to the suppressors *suI*$^+$, *suII*$^+$ and *suIII*$^+$ (ref. 4), that is, sensitivity to ultraviolet light and MMS is suppressed and polymerase levels are increased. If the *polA1* mutation is responsible for the increased frequency of deletions in strain P3478, this high deletion frequency might be suppressible by various amber suppressors. To test this expectation, we introduced a *trpA* amber mutation (A9761) into strains

* Each *tonB-trp* deletion frequency is an average of four or more independent determinations.

† Approximately 5×10^8 cells from a fresh L-broth culture were spread on nutrient agar–cysteine plates supplemented with either 0·04 or 0·06 per cent MMS. After 48 h at 37° C, MMS-resistant colonies were picked and checked for resistance to ultraviolet irradiation (540 ergs/mm^2).

‡ Two additional Pol$^+$ and Pol$^-$ isolates were examined and they exhibited similar *tonB-trp* deletion frequencies.

To measure deletion frequencies, four or more cultures (5·0 ml.) of the strain to be examined were grown from a small inoculum (< 100 cells/ml.) to stationary phase (1×10^9–3×10^9 cells/ml.) in L-broth (or L-broth + thymidine for Thy$^-$ strains) at 37° C. An aliquot of each culture (usually 0·1 ml.) was spread on nutrient agar + cysteine (30 μg/ml.) plates with approximately 10^9 particles of φ80vir and 10^9–10^{10} particles of a colicin V, B preparation. The plates were incubated at 37° C for 24–48 h. The resulting *tonB* mutants were then replicated on a medium lacking tryptophan (minimal medium supplemented with 0·1 per cent acid-hydrolysed casein). Trp$^-$ colonies were scored as *tonB-trp* deletions. For strains carrying a *trpA* mutation, the *tonB* colonies were replicated on minimal + casein + indole (10 μg/ml.) plates. In this case, only deletions extending through the *trpA* gene can be detected. (The order of genes in the vicinity of the *trp* operon is *trpEDCBA–tonB–*.) The *tonB–trp* deletion frequency for a particular strain is calculated from an average of all cultures examined and is expressed as the number of *tonB–trp* deletion cells/10^7 viable cells in the stationary phase cultures.

Deletion frequencies were also determined for five other strains carrying independent *pol*$^-$ mutations (Table 1, experiment (*b*)). (These strains are MMS^s, UV^s and exhibit low DNA polymerase activity *in vitro*: unpublished observations by J. Gross and J. Cairns.) All five Pol$^-$ mutants showed a deletion frequency greater than the parental W3110 strain (Table 1, experiment (*a*)). A MMS^r, UV^r revertant of strain P112 (PR112) showed a diminished deletion frequency.

To prove that the increased frequency of *tonB-trp* deletions in P3478 is the result of a genetic alteration in the *polA* region, *polA1* was introduced into a *polA*$^+$ *cysB*$^-$ *metE*$^-$ stock by cotransduction with *metE*$^+$ (ref. 4). (Repeated attempts to grow phage Plkc on strain P3478 were unsuccessful. Lysates with titres of about 10^8/ml. were, however, obtained with Plc*lr*.) Met$^+$ transductants of each phenotype (Pol$^+$ or Pol$^-$) were examined for *tonB-trp* deletion frequencies. Values for a Pol$^+$ derivative (MEP 8) and a Pol$^-$ derivative (MEP-3) are listed in Table 1, experiment (*c*). All the Pol$^-$ strains examined P3478 and PR3478 by transduction. It was then possible, in subsequent experiments, to construct Pol$^-$ and Pol$^+$ strains carrying *suI*$^+$, *suII*$^+$ or *suIII*$^+$ by transducing in the appropriate suppressor and selecting for suppression of the *trpA* amber mutation. The average *tonB-trp* deletion frequency determined for each *polA1* Su$^+$ strain was compared with a Pol$^+$ strain (revertant) carrying the same suppressor. The data of Table 2 show that all three amber suppressors reduced the relative increase of *tonB-trp* deletions (*polA1*/*polA*$^+$) in the *polA1* strains. Only *suIII*$^+$, however, completely suppressed the *polA1* mutation. Furthermore, whereas all the suppressors reduced the frequency of deletions in the *polA1* strains relative to the appropriate Pol$^+$ Su$^+$ control, only *suIII*$^+$ significantly reduced (85 per cent) the absolute deletion frequency of the *polA1* strain.

The response of the *polA1* strains to the different amber suppressors was variable, and therefore the same suppressor strains were examined for their sensitivity to ultraviolet irradiation. Ultraviolet survival curves are shown

in Fig. 1. *SuIII*$^+$, which efficiently eliminated the increased frequency of *tonB-trp* deletions in the *polA1* strain (Table 2), also totally suppressed the ultraviolet sensitivity of that strain while *suI*$^+$ and *suII*$^+$, which only partially suppressed the increased frequency of deletions, incompletely relieved ultraviolet sensitivity. Thus the ability of the different suppressors to reduce the frequency of deletions in the *polA1* strains correlates somewhat with their ability to suppress ultraviolet sensitivity. Strain PR3478, although exhibiting a low deletion frequency (Table 1), is still slightly ultraviolet sensitive (Fig. 1); this suggests that this strain has not reverted to the wild-type configuration. The *polA1* mutant was examined for a mutator effect by determining the reversion frequency of *trpA46* in Pol$^+$ and Pol$^-$ strains. (*TrpA46* is reverted by many base pair changes[7].) The results obtained indicate that *polA1* has little or no mutation activity.

Table 2. EFFECT OF AMBER SUPPRESSORS ON THE DELETION FREQUENCY OF *polA1* STRAINS

Suppressor*	*tonB-trp* deletions/viable cell ($\times 10^7$)† *polA*$^+$	*polA1*	*polA1*/*polA*$^+$	Percentage of control
Control (Su$^-$)	0·24	7·3	30·0	—
suI$^+$	0·51	5·3	10·0	33
suII$^+$	0·98	15·2	15·5	52
suIII$^+$	0·82	1·1	1·3	4

* *polA*$^+$ and *polA1* strains carrying each suppressor type were constructed as described in the text.

† Each *tonB-trp* deletion frequency is an average of twelve or more independent determinations.

How can the effect of the *polA1* mutation on the frequency of *tonB-trp* deletions be interpreted in terms of what is known about the processes involved in the repair of ultraviolet damage? Dark repair probably involves three processes: an endonuclease makes a single strand nick[8,9]; the damaged region is excised and repaired[6,10]; the repaired segment is rejoined to the parental DNA strand by a polynucleotide ligase[11–13]. Table 1 shows that impairment of any of these processes does not necessarily result in an abnormal frequency of deletions. Strains with mutations in genes *uvrA*, *B* or *C* and which therefore presumably lack the nicking function[14] have deletion frequencies comparable with their Uvr$^+$ parent. The frequency of deletions is also unchanged in ultraviolet-sensitive strains defective in genes *uvrD* or *ras*. These strains are capable of excising pyrimidine dimers[15,16] and therefore presumably are deficient in some process subsequent to nicking. In addition, ultraviolet-sensitive strains exhibiting a Rec$^-$ phenotype produce deletions at a frequency indistinguishable from that of Rec$^+$ strains[1,17–19]. Of the ultraviolet-sensitive strains examined therefore only strains defective in DNA polymerase activity *in vitro* exhibit an abnormal deletion frequency.

The properties *in vitro* of the DNA polymerase of *E. coli* suggest that this enzyme could participate in the excision-repair function *in vivo*[6]. In this case, a mutant deficient in DNA polymerase activity should be extremely sensitive to ultraviolet light and should be unable to perform normal repair replication. The results of a study of ultraviolet repair in a *PolA1* mutant strain[20] indicated that, following ultraviolet irradiation, the *polA1* mutant could still excise pyrimidine dimers and was as capable as its parent of performing repair replication (Cooper and P. Hanawalt, unpublished observation). The average molecular weight of the single strands of the DNA from the mutant (in an alkaline sucrose gradient), however, remained lower than that of the parent for at least 90 min after irradiation. Thus the *polA1* mutant was unable to rejoin efficiently the repaired DNA fragments. Assuming that DNA polymerase does catalyse excision-repair, these workers suggest that the defective polymerase of the *polA1* mutant may be capable of carrying out repair replication, *in vivo*, but may impair normal ligase function.

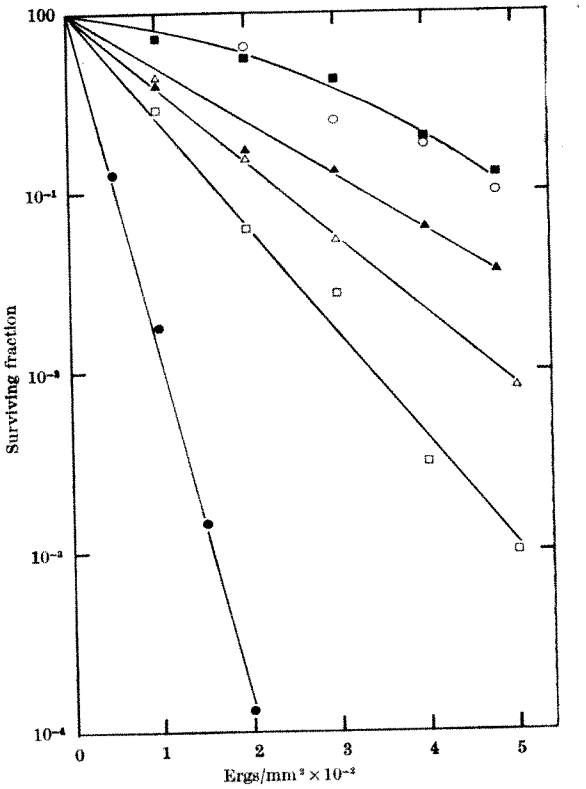

Fig. 1. Ultraviolet survival curves of various suppressed *polA1* strains. Cultures were grown at 37° C in L-broth to approximately 10^8 cells/ml., centrifuged and resuspended in 10 volumes of saline. 10 ml. samples were placed in glass Petri plates and irradiated with a dose of 10 ergs/mm^2/s. At appropriate intervals, aliquots were removed, diluted in saline and spread on nutrient agar–cysteine. The plates were counted after 20 h at 37° C. ○, W3110 (Pol$^+$); ●, Su$^-$*polA1*; △, Su$^-$Pol$^+$ (revertant); ▲, *suI*$^+$*polA1*; □, *suII*$^+$*polA1*; ■, *suIII*$^+$*polA1*.

On the basis of this interpretation we tentatively conclude that the high frequency of *tonB-trp* deletions observed in Pol$^-$ mutants results from an increased number of unrepaired single-strand breaks in DNA.

We thank Dr J. Cairns for the Pol$^-$ strains and for unpublished data on these strains, Dr P. Hanawalt for valuable discussion, and Maja Tavan for assistance in mapping the deletions. This work was supported by grants from the National Science Foundation and the US Public Health Service. M. B. C. is a postdoctoral fellow of the Medical Research Council of Canada.

NATURE VOL. 228 NOVEMBER 14 1970

Prebiotic Synthesis of Polypeptides by Heterogeneous Polycondensation of Amino-acid Adenylates

by
M. PAECHT-HOROWITZ
J. BERGER
A. KATCHALSKY
Weizmann Institute of Science, Rehovot

Certain types of clays may have played a catalytic part in the evolution of polypeptides. The active forms of amino-acids, concentrated by adsorption on the clay particle surface, are shown to condense to form polypeptides of different but discrete sizes.

THE prebiotic synthesis of biopolymers probably involved the condensation and dehydration of active monomers under the conditions prevailing in the primaeval ocean[1]. Various models have been proposed to explain the polycondensation process and several experiments have been carried out on peptide formation in aqueous media. We have studied the polymerization of free and substituted amino-acid phospho-anhydrides[2-5] which have an energy content high enough to permit the formation of peptide bonds even at high dilution and physiological *p*H, and at room temperature. Steinman *et al.*[6] obtained diglycine from the condensation of dicyandiamide at acid *p*H values. Because dicyandiamide might be produced from the primitive atmosphere, and because its reactivity is similar to the cyclodiimide of Khorana[7], it may well have been the starting material for primaeval biosynthesis. In our experiments, however, extensive thermal polymerization of phosphates of amino-acids and of dicyandiamide only occurred in anhydrous conditions[8,9]; it is unlikely that such conditions existed.

The primary difficulty in imagining the polymerization process going so far in the free ocean is, as J. D. Bernal suggested, the extreme dilutions of the system. A large scale concentration of the products would be an absolute necessity for evolution, but it occurred to him that adsorption on very fine clay deposits of marine or fresh water could provide the favourable conditions for concentration. Movement of the clay might then have blocked further transformations of the primary photochemical products[10].

On the basis of this idea, some workers have used clays as a support for amino-acid synthesis[11]. Here, we show that certain clays, in particular the montmorillonites, can act as heterogeneous catalysts of the aqueous polycondensation of active forms of amino-acids. As predicted by Bernal, the presence of clay particles in the polymerization medium strongly inhibits competitive hydrolysis of the active groups and enables rapid formation of peptide bonds in physiological conditions.

Because the first step in the cellular synthesis of proteins is the formation of amino-acid adenylates, we chose the adenylates as model substances for active forms of amino-acids. It was assumed that amino-acid adenylates were synthesized spontaneously in the primaeval ocean from amino-acids formed in prebiotic conditions[12-14] and from ATP which can be synthesized spontaneously in an aqueous medium equilibrated with the primaeval atmosphere[15].

A series of polycondensation experiments was done in the presence of materials such as ion exchangers (cellites, amberlites and so on), silica gel, colloidal metal suspensions (copper, cobalt, iron and ultrasonicated mercury), inorganic polyphosphates and phosphate esters having long aliphatic chains. In all these trials only the cobalt and copper colloids and the aliphatic phosphate esters enabled the formation of higher peptides, and they were formed in rather low yields.

Among the clays, appatites and kaolinates were found not to affect polymerization, and only the highly swelling clays, such as the illites and montmorillonites, exhibited a marked catalytic activity. The permutites, which are regarded as one of the geological precursors of the montmorillonites but which do not swell, displayed no catalytic activity.

Free adenylic acid does not adsorb to the surface of montmorillonite particles; amino-acids adsorb at acid *p*H values but not at *p*H values higher than seven[16]. Amino-acid adenylates, however, adsorb up to an adsorption value of 10^{-3} moles/g montmorillonite. Assuming that montmorillonite disperses completely to single platelets, the area per g would be 7×10^6 cm^2. If the area per adsorbed alanine-adenylate is 50 Å^2, the maximum adsorption at full coverage would be 14×10^{20} molecules/g or $2{\cdot}3 \times 10^{-3}$ moles adenylate/g. The maximal surface coverage, therefore, corresponds to approximately 30 per cent of the total montmorillonite area.

Montmorillonite samples (Montmorillonite No. 25, John C. Lane Tract, Upton, Wyoming), prepared according to Posner[17], were fractionated centrifugally into platelets of diameters ranging from 550 Å to 2000 Å. The thickness of the platelets is about 10 Å. Although both the extent of adsorption and the polymerization rate depend on the particle size, the variation is not very great, so that a particle size of 700 Å was chosen for the experiments reported below.

Some polycondensation experiments were carried out with prolyl adenylate and diprolyl adenylate, but most of the data were obtained from studies with alanyl adenylate. It seems that copolymerization between alanyl adenylate and prolyl adenylate proceeds very easily in the presence of montmorillonite. It was found that the mechanism of polycondensation in homogeneous solution is different from that with heterogeneous catalysis. Homogeneous polymerization is always preceded by a hydrolytic liberation of the free amino-acid. This is represented by equation (1) in which A represents amino-acid, P represents adenylate and A∼P represents active amino-acid adenylate

$$\mathrm{A{\sim}P} \xrightarrow[k_h]{\mathrm{H_2O}} \mathrm{A+P} \qquad (1)$$

The free amino-acid subsequently interacts with the adenylate to give, in consecutive steps, short peptides according to the scheme

$$\begin{aligned} &\mathrm{A+A{\sim}P \rightarrow A_2+P} \\ &\mathrm{A_2+A{\sim}P \rightarrow A_3+P} \quad \text{and so on} \\ &\mathrm{A_i+A{\sim}P \rightarrow A_{i+1}+P} \end{aligned} \qquad (2)$$

where A_i denotes an i-meric peptide.

Because hydrolysis is considerable, the product is largely free monomeric amino-acid and, according to equation (2), all the peptides formed are free of adenylic

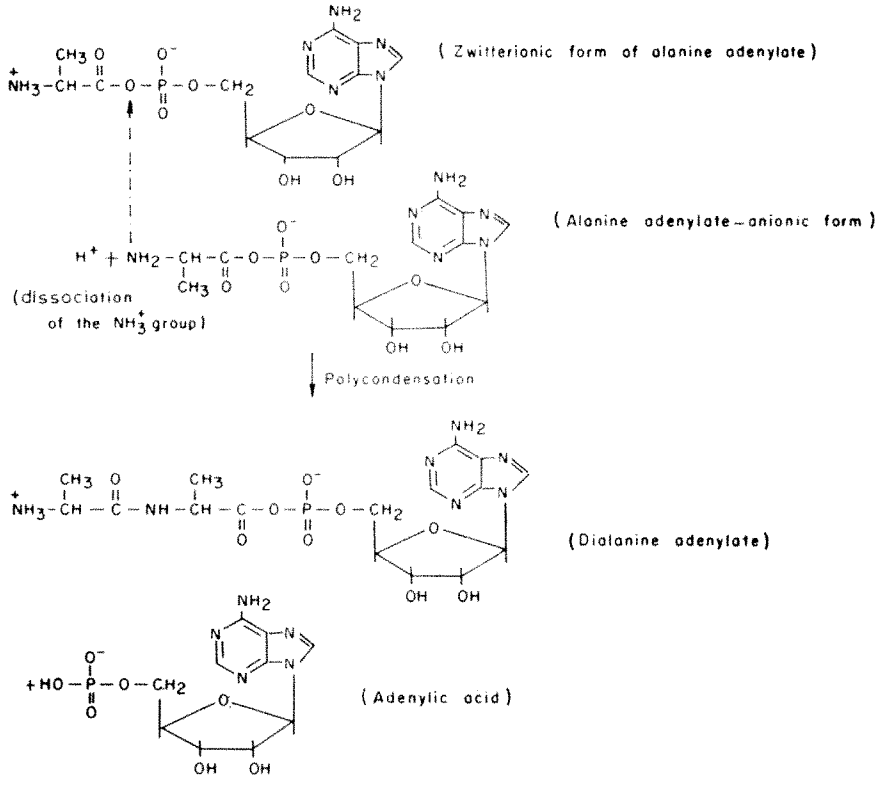

Fig. 1. The first propagation step in the heterogeneous polycondensation of alanyl-adenylate.

acid residues. Heterogeneous polycondensation proceeds in a different manner: generally, no free amino-acid is obtained, so that hydrolysis is largely inhibited by the surface adsorption. Moreover, a high percentage of the peptides obtained carries terminal adenylic acid. Unlike the anhydrides, these terminal groups do not interact with hydroxamic acid at neutral *p*H but do react at very high *p*H and seem to consist of an ester of an amino-acid with the adenylic OH groups of the ribose residue. A plausible reaction scheme for the catalysed polycondensation is therefore

$$\begin{aligned} &A\sim P + A\sim P \rightarrow A_2\sim P + P \\ &A_2\sim P + A\sim P \rightarrow A_3\sim P + P \\ &A_2\sim P + A_3\sim P \rightarrow A_5\sim P + P \quad \text{and so on} \end{aligned} \tag{3}$$

or the general propagation process:

$$A_i\sim P + A_j\sim P \rightarrow A_{i+j}\sim P + P \tag{4}$$

The termination step can be written as

$$A_i\sim P \rightarrow A_i - P \tag{5}$$

where the active phosphoanhydride bond $\sim P$ is converted to the inactive ester bond $-P$.

A closer inspection of the process reveals a few other important points. The organic formulae for the process of equation (3) are depicted in Fig. 1. It will be observed that an essential condition is the dissociation of the ammonium groups, which can take place only in an alkaline medium; polymerization would be inhibited in an acid medium. Fig. 1 demonstrates that each polymerization step liberates the strong adenylic acid which acts as a negative feed-back control on the polycondensation process. To maintain a constant rate of polymerization, therefore, alkali has to be added. In a similar manner, the termination reaction (equation (5) and Fig. 2) is an acidifying process which has to be controlled.

On the basis of these observations, the polycondensation was carried out in the following way: 25 mg montmorillonite was suspended in 50 ml. of water brought to *p*H 7·8–8·5. To the suspension was added 1 mM alanyl adenylate (418 mg), in portions of 10 mg dry powder at time intervals of 10–12 min. The amount of catalyst is sufficient to absorb all of the monomer; within 10 min turnover is complete and a new batch of material can be added. Throughout the experiment a constant *p*H value was maintained in the reaction mixture by means of a *p*H-stat which controlled the addition of 1 M NaOH or Na_2CO_3 to the reaction mixture. Because the alkali additions are a measure of the reaction rate, the time course of the reaction could be followed. It was typical of a heterogeneous polymerization: the rate developed during a few hours from a low to a constant stationary value. When no further alkali addition was required a stationary concentration of active $\sim P$ groups had been reached.

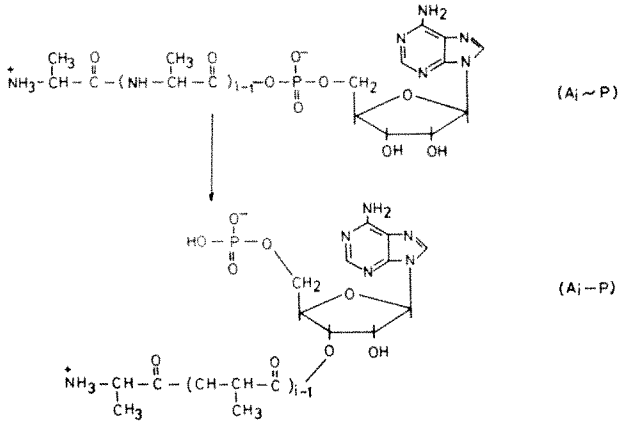

Fig. 2. The termination step in the heterogeneous polycondensation of alanyl-adenylate.

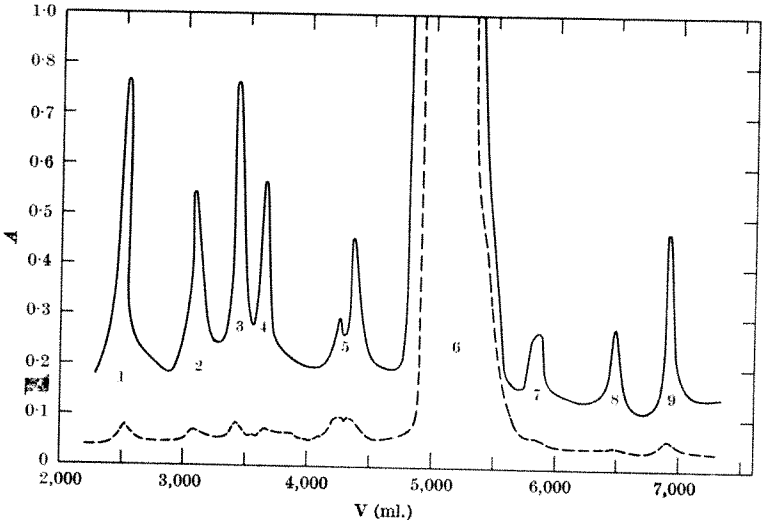

Fig. 3. Chromatography of fraction II on 'Sephadex G-25', with gel bed 3×4×150 cm. The peptides of each peak are described in Table 2. In addition, peaks 5 and 8 represent chiefly adenylic acid; the materials of peaks 7 and 9 are inorganic salt and residual alanyl-adenylate respectively. Elution solvent, 0·05 M HCl; - - - -, absorbance at 216 nm; ———, absorbance at 258 nm.

At the end of the reaction the montmorillonite was separated by centrifugation, and washed a few times with distilled water. The total aqueous reaction medium was ultrafiltered through membranes of various pore sizes and then subjected to chromatographic separation on columns of 'Sephadex', with water and dilute HCl as solvents.

To follow the efflux out of the column, a double beam spectrophotometric recorder was set up at the entrance to the fraction collector. One beam, of wavelength 258 nm, recorded the exit of only the free or bound adenylic acid; the other beam (216 nm) recorded the exit of both peptides and adenylic acid. Thus it was possible to determine simultaneously bound adenylic acid groups and total peptide bonds.

In a typical experiment, 1 g alanyl adenylate containing 172 mg alanine was added in 10 mg portions to 25 mg montmorillonite in 50 ml. water at *p*H 8·5. After 24 h the montmorillonite was removed by centrifugation and the reaction mixture was passed through a 'Sephadex G-25' column and eluted with water to give two fractions, I and II.

Table 1. DATA ON PEPTIDES

Peptide molecular weight	Degree of polymerization	Weight (mg)
640	9	10·3
1,120	16	35·2
1,900	27	20·0
Adenylic acid	1	470·5

The fractions were passed through a second similar 'Sephadex' column and eluted with 0·05 M HCl. A major part of fraction I was adenylic acid and the rest was free alanyl peptides. Data are presented in Table 1. The molecular weights of the peptides were determined in an analytical Spinco ultracentrifuge and the values obtained were corroborated by end group determination. High voltage paper electrophoresis showed that each of the peptide fractions was practically monodisperse.

The elution profiles of both fractions were unusual, and suggested an irregular but discrete distribution of molecular weights. A typical elution profile is shown in Fig. 3. Here, high polypeptides of molecular weight up to 4,000 and a degree of polymerization greater than 50 are found. In this molecular weight range all the peptides carry terminal adenylic acid residues in accord with the mechanism discussed above. It is also remarkable that practically no hydrolysed monomer was found in the reaction mixture. This indicates that montmorillonite protected the adenylates efficiently and allowed their full polymerization.

Similar behaviour was observed with a more primitive form of clay called illite, which is regarded as one of the geological precursors of montmorillonite, and which is able to swell to some extent. It was found that in the presence of illite, all the monomers polymerized, although the degrees of polymerization were lower than in the present experiments, ranging between 10–16 alanine residues.

As pointed out by Calvin[18], the selection of chains of certain molecular weights from a large number of possibilities is typical of living processes. The finding that heterogeneous clay polycondensation is selective prompts further consideration. In an attempt to explain the grouping of molecular weights around 9, 16 (18), 27, 32 (36), 42 (45) and 54 (56), which seem to be multiples of a basic nonamer, we assumed some periodic nine membered structure in the montmorillonite surface or the particle edges. We failed to discover such a repeating unit and, moreover, the repeating number was different at other concentrations or with other particle sizes. Another possibility is that the discontinuous distribution is a case of a dissipative structure based on the coupling of diffusional and chemical flows. It will be recalled that during the polymerization process free adenylic acid is

Table 2. PEPTIDES OBTAINED ON POLYCONDENSATION OF ALANYL ADENYLATE

Peak No. from Fig. 3	Molecular weight of peptide adenylate	Degree of polymerization	Weight (mg)
4	2,130	30	8
2	2,310	32	5·2
1	3,020	42	10·8

6	Adenylic acid	1	260·1

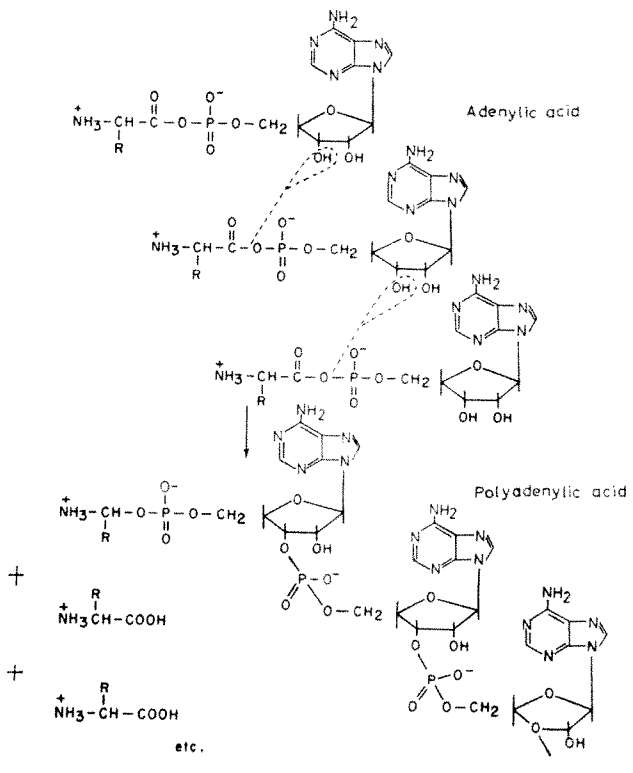

Fig. 4. Hypothetical formation of polyadenylic acid from amino-acid adenylates.

liberated which inhibits polycondensation by preventing the non-reactive ammonium group from dissociating with release of a proton and thereby producing the highly reactive terminal $-NH_2$. Thus we can readily envisage that a pulse of rapid polycondensation will produce a high local concentration of acid molecules which will stop the process until the adenylic acid diffuses out. After this diffusion, a second pulse will occur which will again be stopped after, say, nine steps by the accumulated acidity. For the joint operations of reaction and diffusion to give a periodic phenomenon therefore a correct matching of the processes and a suitable time lag are required.

Although many features have still to be studied, for example the dependence of the rate of polycondensation on the nature of the amino-acid and the nucleotide, the production of copolymers and their selective evolution from random monomeric mixtures, and, indeed, the influence of various physical factors on the process as a whole, it seems that the dissipative structures may play a part in all these reactions. The variable *p*H on the surface of the montmorillonite suggests other possibilities: it will be noted that the polycondensation and termination reactions described by equations (4) and (5) do not exhaust the combination possibilities of amino-acid nucleotide anhydrides and a possibility is the formation of polynucleotides with the liberation of free amino-acid.

The conditions for this process are unknown. It is, however, conceivable that in the periodic variation of *p*H the scheme according to Fig. 4 will predominate in one phase while the scheme according to Fig. 1 will predominate in another. Thus we could envisage the simultaneous formation of peptides and polynucleotides during an oscillatory process of clay catalysis.

We thank Professor F. R. Eirich from the Polytechnic Institute of Brooklyn for continued help and for many stimulating discussions. This work was supported by a grant from the US National Institutes of Health.

Mapping of the Combining Sites of Antibodies specific for Poly-L-alanine Determinants

by
ISRAEL SCHECHTER
Department of Chemical Immunology,
Weizmann Institute of Science,
Rehovot

By modulating the structural features of a series of haptens and observing their strengths of interaction with antibody, conclusions are drawn which cast doubt on previous interpretations of hapten–subsite fitting.

THE hapten inhibition method is commonly used to study the size and nature of the combining sites in antibodies[1,2]. Because an antibody combining site is rather large (it can accommodate, for example, up to six glucose units[2], or three to seven amino-acid residues[3–9]), it is suggested that, for the purpose of mapping, it be divided into several subsites[10], defined as regions on the antibody molecule which interact with a particular portion of the antigenic determinant (or hapten). Knowing the size of the binding site (or the number of subsites), it is possible to map it in terms of the particular interactions which the various subsites can exhibit. This approach was used with advantage in exploring binding properties of chain-splitting enzymes such as lysozyme[11,12], papain[13–16], carboxypeptidase A[17], and others[18–20]. For example, it was found that the active site of papain can interact simultaneously with a stretch of seven amino-acid residues, and the binding energies of different amino-acid side chains in two subsites (out of a total of seven) were evaluated.

I have studied the properties of antibodies specific to poly-L-alanine chains (carrying free α-amino groups). In this case the combining site is visualized as being composed of several subsites, each accommodating one amino-acid residue of the antigenic determinant (Fig. 1). The extent and properties of the binding site are deduced from the correlation between the structural features of series of haptens and their strength of interaction with the antibody (as manifested by their capacity to inhibit the precipitin reaction). The types of structural changes applied here were: (1) elongation of the peptide chain of the hapten; (2) blocking of the amino function or the

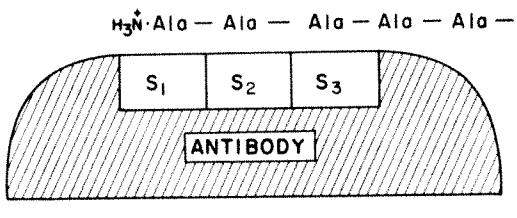

Fig. 1. Schematic representation of the complex formed between a poly-L-alanine chain and its specific antibody. The combining site of the antibody is composed of three subsites (S_1 to S_3) each accommodating one amino-acid residue of the antigenic determinant. The N-terminal L-alanine residue occupies S_1, the penultimate residue S_2, the third residue S_3, and the other alanine residues are outside the region of the combining site.

carboxyl function of the peptides; (3) replacement of an L-alanine residue in the peptide by its D antipode; (4) replacement of one L-alanine residue by a glycine, L-phenylalanine or L-valine residue. The influence of these changes on inhibitory power is taken as evidence of interaction of the modified portion of the peptide with the combining site.

It is well known that antibodies even to a unique determinant are heterogeneous, but this work demonstrates that it is possible, nevertheless, to attribute specific properties to the various subsites of the combining site. The results therefore represent average properties of subsites in different antibody molecules. The detailed structure of the subsites in different molecules should vary and work is in progress to evaluate the degree of variation of these properties by studying the combining sites of subfractions of this antibody population.

Antibodies to poly-L-alanine chains were obtained from rabbits immunized with poly-L-alanyl–human serum albumin[5]. A molecule of antigen contained on average 25 chains of polyalanine, each composed of 4·8 L-alanine residues. Pooled antisera were absorbed on poly-L-alanyl–rabbit serum albumin–cellulose conjugate according to Robbins *et al.*[21]. The purified antibodies were eluted from the immunoadsorbant with 0·010 M tetra-L-alanine in phosphate-buffered saline (*p*H 7·3) and then dialysed against the solvent to remove the peptide. The amount of purified antibody was 36 per cent of the total present in the original serum, and 72 per cent of it was precipitated by poly-L-alanyl–rabbit serum albumin. Quantitative inhibition studies of the precipitin reaction were performed as described[5]. The synthesis of alanine peptide diastereoisomers used as inhibitors has been reported[22]. Other peptides were prepared by the hydroxysuccinimide method[23]. The purity of these peptides was higher than 99 per cent as checked by high voltage electrophoresis at *p*H 1·4 and by chromatography in butanol–acetic acid–water.

Table 1. INHIBITION OF THE PRECIPITIN REACTION OF ANTIBODIES TO POLY-L-ALANINE BY ALANINE PEPTIDES

	Peptide concentration (mM) at 50 per cent inhibition				
Ala_n	H-L$_n$-OH	H-L$_{n-1}$D-OH	H-DL$_{n-1}$-OH	H-L$_n$-NH$_2$	Ac-L$_n$-OH
Ala_1	> 8·5 (6%)			> 8·5 (42%)	
Ala_2	8·5	> 8·5 (25%)		0·32	> 3 (0%)
Ala_3	0·32	2·4	> 3 (13%)	0·08	> 3 (10%)
Ala_4	0·09	0·11	> 3 (31%)	0·07	> 3 (22%)
Ala_5	0·08	0·07	> 3 (30%)	0·07	

Reaction mixtures contained purified antibodies, poly-L-alanine–rabbit serum albumin (serving as precipitating antigen) and peptide. A number of concentrations of peptides were used to determine the point of 50 per cent inhibition. When 50 per cent inhibition was not achieved, the percentage inhibition obtained at the maximal peptide concentration used is given in parentheses. H-L$_n$-OH, free L-alanine peptide; H-L$_{n-1}$D-OH, free alanine peptide with a D residue at the C terminus; HDL$_{n-1}$-OH, free alanine peptide with a D residue at the N terminus; H-L$_n$-NH$_2$ amide of alanine peptide; Ac-L$_n$-OH, N-acetyl alanyl peptide.

The degree of inhibition of anti-poly-L-alanyl antibodies by various alanine peptides is given in Table 1. For the purpose of analysis of the data we define subsite S_1 as the one which interacts with the N-terminal L-alanine residue (which is the most exposed in the antigenic determinant), whereas the adjacent residues in the antigenic determinant (or hapten) occupy subsites S_2, and so on (Fig. 1). The inhibitory capacity of free L-alanine peptides increases with their size up to the tetrapeptide, Ala_5 being as good an inhibitor as Ala_4. The common interpretation of these results would be that the combining site can accommodate a tetrapeptide[2,5], and in terms of the subsite concept the conclusion would be drawn that it is composed of four subsites. As I shall show, however, a more rigorous procedure shows the presence of only three subsites.

Precise information on the properties of the combining site can be derived from comparing haptens of equal size which differ from one another in one particular feature, rather than from studying the effect of elongation in a homologous series of peptides. This is because the stronger binding caused by elongation does not necessarily arise from additional interaction by the extra piece, but can also be attributed to the abolition of unfavourable interactions in the smaller hapten. Thus the finding that Ala_4 is a better inhibitor than Ala_3 by a factor of 3 does not prove the existence of subsite S_4, for it may reflect a lack of interaction between the carboxylate of Ala_3 and subsite S_3. Indeed, the inhibitory capacity of the amide of Ala_3, which is equal in size to Ala_3 but without the carboxylate ion, is much better than that of Ala_3 and similar to that of Ala_4 and Ala_5 (see Table 1). Other erroneous conclusions could be drawn from the use of the free peptide series alone. For example, the contribution of the third residue is over-estimated by using data obtained with free peptides, for elongation from di to tripeptide increases inhibitory efficacy by a factor of 26. The data obtained with the corresponding amides give a factor of 4 (Table 1), which seems to be a better estimate for this elongation.

The effects of systematic variations in the structure of tetra-L-alanine are shown in Tables 2 and 3. Replacement of an L-alanine residue by D-alanine reduces binding when it occurs in the first three positions, but it is not effective in the fourth position (from the N-terminal end). The effect of diastereoisomeric replacement is stronger the closer it is to the N-terminal end (Table 2). Substitution of L-alanine by L-phenylalanine (or L-valine) in the N-terminal position reduces binding markedly. This effect diminishes gradually with distance from the N-terminal end, and disappears in the fourth position (the C-terminal end). A similar pattern is observed by substituting glycine for L-alanine (Table 3).

Table 2. THE EFFECT OF DIASTEREOISOMERIC REPLACEMENTS ON THE INHIBITORY CAPACITY OF TETRA-ALANINE PEPTIDES

H-Ala_4-OH configuration	Concentration (mM) at 50 per cent inhibition
LLLL	0·09
LLLD	0·11
LLDL	1·8
LDLL	> 3 (28%)
DLLL	> 3 (31%)

Reaction mixtures as in Table 1. When 50 per cent inhibition was not achieved, the percentage obtained at the maximal peptide concentration used is given in parentheses.

Because the peptide determinants in the antigen have no free carboxyl groups, more precise information on the combining site will be obtained by means of peptide amides than by the use of free peptides. A comparison between the amides and the free peptides shows that the binding of H-Ala_n-NH_2 is almost equal to that of H-Ala_{n+1}-OH (Table 1). This means that in free peptides either the carbon portion of the C-terminal residue does not interact with the combining site, or that interference caused by the carboxylate of H-Ala_n-OH is counterbalanced by the interaction of the carbon portion of the C-terminal alanine in H-Ala_{n+1}-OH. The latter conclusion is correct, for Ala_3(L$_3$) is a better inhibitor than Ala_3(L$_2$D). The finding that amidation improved the inhibitory capacity of alanine, Ala_2 and Ala_3 (but not of Ala_4 and Ala_5) shows that the carboxylate ion interferes with binding up to the third residue.

Thus, diastereoisomeric replacements, the presence of carboxylate ion and changes in bulkiness of the side chain (an increase Ala→Phe, or decrease Ala→Gly) are felt over three residues from the N-terminal end of an L-alanine peptide. The size of the combining site is therefore such as to accommodate three L-alanine residues; in other words, it is composed of three subsites (S_1, S_2 and S_3, Fig. 1). Stereospecificity is very strong in S_1 and S_2, and somewhat less in S_3 (Table 2). The structural requirements for the interaction of a ligand with S_1 are very stringent, less so in S_2 and even less in S_3. The strict requirements of S_1 are deduced from findings that N-acetyl-Ala_4(L$_4$) and Ala_5(DL$_4$) (which contain uninter-

Table 3. THE EFFECT OF SIDE CHAIN SUBSTITUTION ON THE INHIBITORY CAPACITY OF TETRAPEPTIDES

Phe Ala Ala Ala	> 3 (24%)	*Val* Ala Ala Ala	> 3 (24%)	*Gly* Ala Ala Ala	2·9

Reaction mixtures as in Table 1. C represents the concentration at 50 per cent inhibition. When 50 per cent inhibition was not achieved, the percentage inhibition obtained at the maximal peptide concentration used is given in parentheses. All amino-acids are L.

rupted sequences of four L-alanine residues) are very poor inhibitors compared with Ala_4 (Table 1): a non-N-terminal L-alanine residue does not bind efficiently in S_1. Also, the highest degree of space limitation towards L-phenylalanine and L-valine residues is exhibited by subsite S_1 (Table 3).

Because a glycine residue occupies less space than an alanine residue the inhibition data can be used, by a first approximation, to calculate the binding energy of the methyl side chain of L-alanine ($-\Delta^2F$) in the various subsites. For this purpose the inhibitory capacity of pairs of peptides of equal size is compared, using the relation $-\Delta F = RT \ln(C_{Pep}/C_{Ala})$[24]. For example, the free energy of binding of the β methyl in S_2 is calculated by using the concentrations, at 50 per cent inhibition, of $AlaGlyAla_2(C_{Pep})$ and $Ala_4(C_{Ala})$. The $-\Delta^2F$ values so obtained are summarized in Table 4 and also show that in spite of the different inhibitory potencies of Ala_3 and Ala_4, the same $-\Delta^2F$ values for the binding of a methyl group in S_1 are obtained from the pairs $GlyAla_2$ and Ala_3 as well as $GlyAla_3$ and Ala_4. These findings strongly support our assumption that the peptides are lined up on the combining site in such a way that the free N-terminal residue always occupies the same subsite, that is, S_1. In all cases examined, the binding energies of the methyl groups in the various subsites were found to be independent and thus additive. The example given shows that the interaction of the methyl group in S_1 is independent of the presence of a charged carboxylate in S_3. In this connexion it can be mentioned that binding of a methyl in S_3 is independent of the presence of β-methyl in the fourth position (compare $Ala_2GlyAla$ and Ala_2Gly_2 with Ala_4). The additivity is demonstrated by the fact that in peptides in which two alanine residues were replaced by glycines the $-\Delta^2F$ values calculated were equal to the sum of the $-\Delta^2F$ values of the appropriate single replacements. For example, the change in binding energy between Gly_2Ala_2 and Ala_4 was found to be 3·38 kcalories mole^{-1}, which is the same as the sum of the $-\Delta^2F$ values determined separately for S_1 and S_2 (2·1 + 1·25 = 3·35 kcalories mole^{-1}; see Table 4 for other examples).

Table 4. BINDING ENERGY OF THE METHYL SIDE CHAIN OF L-ALANINE IN THE VARIOUS SUBSITES OF ANTIBODIES TO POLY-L-ALANINE CHAINS

Peptide	C (mM)	C_{rep}/C_{Ala}	$-\Delta^2F$ (kcalories mole^{-1})	Subsite explored
Ala Ala Ala Ala	0·09			
Gly Ala Ala Ala	2·9	32	2·1	S_1
Ala *Gly* Ala Ala	0·70	7·8	1·25	S_2
Ala Ala *Gly* Ala	0·18	2·0	0·42	S_3
Ala Ala Ala *Gly*	0·09	1·0	0	
Gly Gly Ala Ala	24	266	3·38	S_1+S_2
Ala Ala *Gly Gly*	0·17	1·9	0·39	S_3
Ala Ala Ala	0·32			
Gly Ala Ala	10	31	2·09	S_1
Ala *Gly Gly*	5·0	16	1·67	S_2+S_3

Reaction mixtures as in Table 1. C represents the concentration at 50 per cent inhibition. The free energy of binding of the methyl side chain (at 36° C) was calculated from the relation $-\Delta^2F = RT \ln(C_{rep}/C_{Ala})$, using peptides of equal size. All alanine residues are L.

The finding that the methyl groups of an alanine peptide are bound in the three subsites with different energies (2·1 kcalories mole^{-1} in S_1, 1·2 kcalories mole^{-1} in S_2 and 0·4 kcalories mole^{-1} in S_3) may give an important clue to the architecture of the binding site. Because it is reasonable to assume that hydrophobic interaction is the main source of binding energy, the differences observed seem to reflect differences in the degree of contact. In other words, one might say that in S_1 a methyl group of the hapten fits into a depression which completely surrounds it, in S_2 the depression is either shallower or wider, producing less contact, whereas in S_3 contact is still weaker. This would also account for the fact that S_1 cannot contain a phenyl group, S_2 accommodates it with difficulty, and in S_3 the interference is rather slight. The varying degrees of stereospecificity of the three subsites also fall into the same pattern.

A similar situation was found to exist in the binding of peptide inhibitors at the active site of papain which specifically binds aromatic residues in S_2 (refs. 14, 15). Binding energies of various amino-acid side chains in two subsites (S_1 and S_2) were determined and correlated with preliminary X-ray diffraction data of an enzyme-inhibitor complex[16]. The methyl side chain of alanine was found to be bound in S_1 with 0·85 kcalories mole^{-1}. The model showed that only about half of it is in hydrophobic contact with the enzyme surface. The phenyl group of phenylalanine was bound with 0·85 kcalories mole^{-1} in S_1 but with 3 kcalories mole^{-1} in S_1. Moreover, in S_1 contact is rather slight whereas in S_2 hydrophobic contact is extensive. It is also of interest that a binding energy of 4 kcalories mole^{-1} for a phenyl group was determined by Karush in the anti-L (or D)-phenyl-(*p*-azobenzoyl-amino) acetate system[25]. In terms of the lock and key theory one may say that a given key (methyl or phenyl group) may fit one lock better than another.

I thank Professor A. Berger and Professor M. Sela for discussion and Mrs Etti Zazepizki for technical assistance.

The imidazole C2-H resonances in the 220 MHz proton magnetic resonance spectra of staphylococcal nuclease have been identified with the aid of computer curve-fitting. Spectra were fitted to Lorentzian curves for the measurement of peak area, and chemical shifts were fitted to theoretical *p*H titration curves for the precise determination of *pK* values. Such a high resolution analysis makes a conformational equilibrium hypothesis involving histidine unlikely in the case of nuclease.

HIGH resolution proton magnetic resonance (PMR) spectroscopy can potentially resolve signals from one kind of amino-acid located in different chemical environments within the three dimensional structure of a protein. At a resonance frequency of 100 MHz, however, only the C2 protons of the imidazole groups of histidine residues have been fully resolved in unmodified proteins[1,2]. Imidazole protons are known to absorb in the low field portion of the spectrum and to have a large *p*H dependent change in chemical shift[3]. It is for these reasons that PMR has been useful in obtaining the microscopic *pK* values of individual histidine residues in proteins[4,5] and in studying their interactions with substrate analogues[6] Because of the low signal strength, however, the crossing of peaks as the *p*H is changed and the presence of other resonances in this region of the spectrum, ambiguities occur which may make identification of resonances equivocal. We present here a computer-assisted study of the low field region of the PMR spectrum of nuclease, using the greater sensitivity and resolution obtainable at 220 MHz[7].

Computer curve fitting[8] was carried out with a least squares program (MODELAIDE)[9], using an IBM 360/50 computer with the IBM 2250 display. The computations were done in two stages. First, the PMR data were fitted to a sum of Lorentzian curves[10], in order to determine peak area (a), chemical shift (δ) and width (σ), even where resonances overlap. Then, the midpoints δ were fitted to theoretical titration curves derived from the Henderson–Hasselbach equation[11]

$$pH = pK + \log [B]/[HB] = pK + \log (\delta_{max} - \delta)/(\delta - \delta_{min}) \quad (1)$$

so that

$$\delta = (\delta_{max} + 10^{(pH - pk)}\, \delta_{min})/1 + 10^{(pH - pK)} \quad (2)$$

where chemical shift is considered a linear function of concentration. This computer analysis facilitates the construction of complete histidine titration curves and the determination of precise *pK* values. To be identified with imidazole C2 protons, resonances must satisfy two criteria: they should have equal area (because each arises from a single proton) and they should titrate between *p*H 5 and *p*H 8 (ref. 3).

The low field portions of 220 MHz PMR spectra of nuclease at various *p*H values are shown in Fig. 1. Although nuclease has only four histidine residues[12] five peaks are clearly visible in many spectra (see, for example, Fig. 1*b*). An example of computer curve fitting of the spectrum in Fig. 1*b* is shown in Fig. 2. This spectrum was fitted with six Lorentzian curves, the baseline being approximated by a single large upfield Lorentzian peak. Initial values of a, δ and σ were estimated; the program then altered these parameters until convergence was achieved. The relative areas of the peaks in this spectrum are indicated in Fig. 2. (No experimental accuracy for area measurements can be quoted in view of different signal/noise ratios in individual spectra and the potential degeneracy of solutions where two or more Lorentzian peaks overlap.)

With increase in *p*H, peaks H-1 to H-4 are observed to shift upfield while the peak labelled X-1 undergoes little change in chemical shift. (X-1 broadens and is difficult to resolve above *p*H 6.) The chemical shifts of these resonances as a function of *p*H are shown in Fig. 3, at two

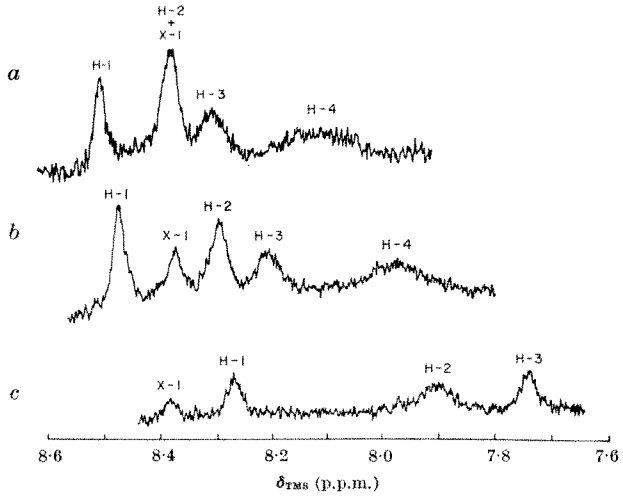

Fig. 1. Spectra were recorded on a Varian Associates 'HR-220' spectrometer at the ambient probe temperature of 22 ± 1° C. Each spectrum was calibrated with the same 6 per cent TMS in CCl_4 sample using the sideband technique, and chemical shift values are in p.p.m. downfield from this standard. Values of *p*H are uncorrected meter readings. All other experimental details are as reported previously[4]. 220 MHz time-averaged PMR spectra of staphylococcal nuclease at 100 mg/ml. in 0·1 M NaCl-^2H_2O (100 per cent). *a*, *p*H 4·56; *b*, *p*H 4·97; *c*, *p*H 6·00. The four peaks H-1 to H-4 are identified as the four C2 imidazole resonances; the peak X-1 does not shift with *p*H. H-3 and H-4 are broader than usual in this sample, but sharpen with increase in *p*H, while H-2 broadens as normal.

concentrations of NaCl. The computer-drawn plots of the Henderson–Hasselbach relationship which gives the best fit in each case and the computed apparent pK values are also shown.

Fig. 3 demonstrates that the titration curves of H-1 and H-2 cross each other. Such chiasmata are fairly common where there are multiple histidine resonances. We have examined both possible continuities after the point of superposition, and find much poorer fits to the theoretical Henderson–Hasselbach relationship in the case where no crossover is assumed. This is indicated by the computer fit in which the relative value of the residual sum of squares without crossover is thirty times greater than with crossover. Thus the computer assisted analysis aids determination of the true continuity.

The different histidine pK values indicate differences in the microscopic environment of each of the imidazole side chains. Ease of protonation is determined by the local dielectric constant and the proximity of positive and negative charges[13]. Attempts to quantitate these effects, as in the Linderstrøm–Lang model of spherically symmetrical charges[14], are inadequate at the molecular level. We have therefore left the results as individual apparent pK values. The effect of increasing salt concentration on these microscopic pK values is difficult to predict because it depends on the sign of charges near the imidazole ring, binding of the cations and anions and possible changes in protein conformation. The major effect of high salt concentration, however, would probably be to shield the imidazole from the increasing number of positive charges on the molecule as pH is lowered. This would explain the rise in the apparent pK.

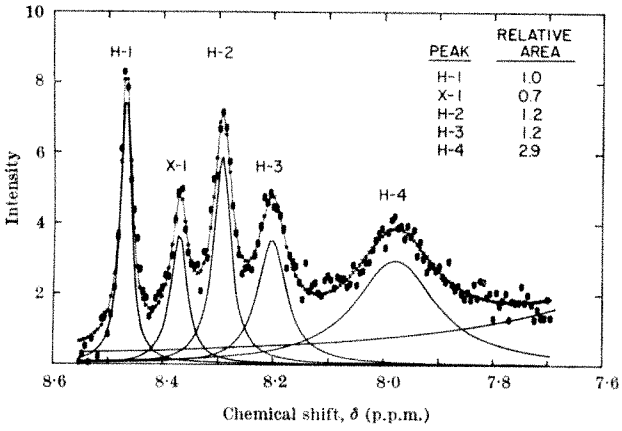

Fig. 2. CALCOMP plot of 220 MHz nuclease spectrum 1*b* fitted with Lorentzian curves. ●, Observed; ★, calculated; ———, components. The computer calculated the areas of the component peaks which gave the best fit to the data; these areas are indicated by their ratio to the area of H-1 (taken as 1·0). The area of peak H-4 is increased because of the presence of several smaller broad resonances absorbing in the same region.

The net result of the curve fitting process applied to many spectra shows that the four peaks H-1 to H-4 are all of essentially equal area (see also ref. 8). When a histidine peak is in the region of the spectrum from 7·8 to 8·1 p.p.m., however, its area is increased (as for H-4 in Fig. 2) by superposition on several smaller resonances in this region. The X-1 resonance characteristically has an area about half that of peaks H-1 to H-4. Further, the peaks H-1 to H-4 titrate as expected, and are therefore identified as the four imidazole C2-H resonances. The peak X-1 and other smaller resonances seem to be of non-histidine origin.

In previous PMR studies at 100 MHz of the same low field region of the nuclease spectrum, Jardetzky and his co-workers[15–18] observed the resonances described here. But they interpreted[17] their data as indicating that one

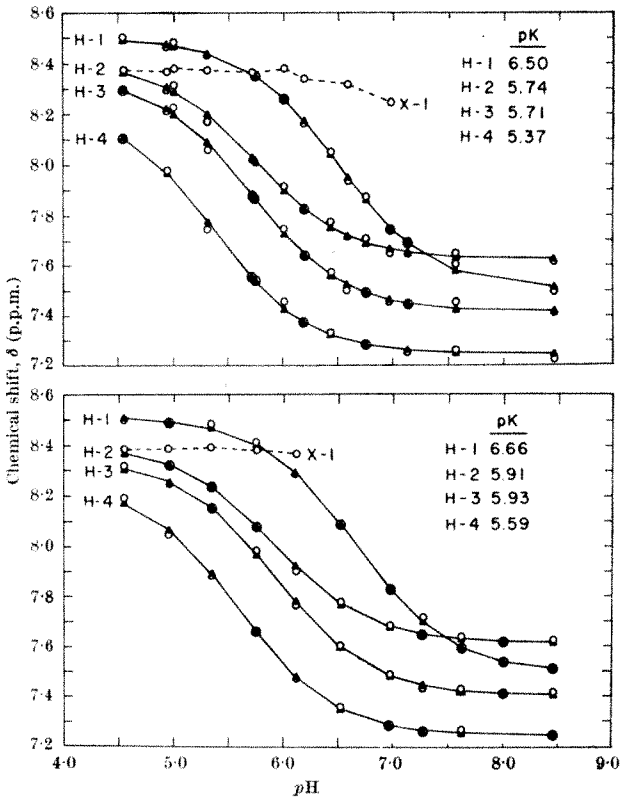

Fig. 3. Titration curves of the imidazole C2-H resonances of nuclease in 0·1 M NaCl (upper) and 0·3 M NaCl (lower). ○, Observed points; ▲, computer calculated points for the best fit to equation 2. The lines connect the calculated points. The separate curves have been traced from CALCOMP plots on the composite figure.

histidine residue is located in two different, slowly exchanging conformational environments. Their interpretation asserts (*a*) that two peaks (which they call H2*a* and H2*b*) have partial proton areas, and sum to unity relative to the other discrete C2-H resonances; (*b*) that the two titration curves* of H2a and H2b are related by the exchange phenomenon, and that neither curve can be described by a single Henderson–Hasselbach equation[8,19]. We correlate their H2a resonance with X-1 and their H2b resonance with H-2. (A number of spectra were also run at 32° C, the temperature used in the 100 MHz study[17], with no alteration in the findings.) We have found that the sum of the areas of these resonances is significantly greater than unity (Fig. 2). This can also be seen in Fig. 1*a*, where the superposition of peaks H-2 and X-1 results in a relative area (2·2) significantly larger than those of H-1 and H-3 (both 1·0). The computer fitted results indicate no significant deviation from the theoretical titration relationship for H-2 (Fig. 3).

A conformational equilibrium in ribonuclease involving a histidine residue has been postulated[8]. The demonstration of such equilibria in several proteins would be important in the interpretation of protein structure in solution. We believe, however, that the higher resolution at 220 MHz, together with the computer assisted analysis of the data, has yielded a more complete understanding of this region of the PMR spectrum which makes this conformational equilibrium hypothesis involving histidine unlikely in the case of nuclease. Other spectroscopic studies show evidence of structural transitions only below pH 5 and above pH 10 for this protein[20,21].

The ability to measure areas of peaks has enabled us to follow the process of denaturation in some detail. The

* In addition to X-1, another resonance of partial proton area was seen with some samples. This corresponds in chemical shift to the chemically equivalent C2 protons of denatured nuclease, and titrates with pH. This peak can be a source of ambiguity in the identification of resonances.

capability of fitting titration data, ascertaining continuity, and determining apparent pK values with precision[8] should extend the usefulness of PMR in studying histidine residues of small proteins and their interactions with substrate analogues.

We thank Dr C. B. Anfinsen for his interest, Mr I. Gillespie for digitizing the spectra, and Mr R. Bradley and Mr R. Tschuden for aid with the spectrometer.

Stability of Binuclear Complexes

by
R. D. CANNON
School of Chemical Sciences,
University of East Anglia,
Norwich NOR 88C,
Norfolk

Empirical arguments lead to a relationship between the stability constant for the formation of a binuclear complex $MXM^{(2m-x)+}$, and that for the corresponding mononuclear complex $MX^{(m-x)+}$. As K_{MX} increases along a series of metal ions M^{m+}, with a given ligand X^{x-}, it is predicted that K_{MXM} will pass through a maximum value, in agreement with available data.

BINUCLEAR complexes are frequently postulated as intermediates in reactions between metal ions in aqueous solution, especially redox reactions. Stabilities of such complexes are clearly important in the discussion of reaction rates[1] and they can also be relevant to the assignment of mechanisms. In reaction 1, for example, a binuclear intermediate is assumed but its lifetime is not known; only the second-order rate constant, K_1k_1, can be measured. By analogy with complexes of other metals, however, K_1 has been estimated[29] to be of the order of $10^{0\pm1}$ M^{-1} (at 25° C), whence $k_1 = 10^{6\pm1}$ s^{-1}. This shows that the redox process, although rapid, is not as fast as the rate of replacement

$$Co^{III}[NH_2(CH_2)_2NH_2](H_2O)OH^{2+} + Cr^{2+} \overset{K_1}{\rightleftharpoons} \{Co^{III}[NH_2(CH_2)_2NH_2](H_2O)OHCr^{II}\}^{4+} \xrightarrow{k_1} Co^{II} + Cr^{III} \quad (1)$$

of water molecules in the coordination sphere of the Cr^{2+} ion. If it had been otherwise, the suggested mechanism would have been untenable. In reaction 2 the binuclear intermediate was observed directly[2] but the valency states had still to be determined

$$cis\text{-}Ru^{III}(NH_3)_4Cl_2^+ + Cr^{2+} \overset{K_2}{\rightleftharpoons} [(NH_3)_4RuCl_2Cr]^{3+} \rightarrow Ru^{II} + Cr^{III} \quad (2)$$

It was argued that the observed value of K_2 (460 M^{-1} at 25° C) was too large for an Ru^{III}–Cr^{II} binuclear species and the assignment Ru^{II}–Cr^{III} was preferred.

Many other cases could be cited where a knowledge (or even a rough estimate) of the tendency to form binuclear species would be of value, but the data are still comparatively sparse. The aim of this article is to propose a general relationship by which stabilities of certain types of binuclear complex may be estimated from those of the corresponding mononuclear species.

Order of Stabilities

Consider two metal ions M^{m+} joined by a ligand X^{x-}; suppose that X^{x-} is a sufficiently strong base to give two conjugate acids $HX^{(x-1)-}$ and $H_2X^{(x-2)-}$, and further

* Coordinated water molecules not shown.
† Where different values are quoted for the same constant, they refer to different ionic media.

that the complex $MX^{(m-x)+}$ can be protonated to yield $MXH^{(m+1-x)+}$. Species of this kind are occasionally found where X^{x-} is a multidentate or highly charged anion[3]; they have also been recognized as intermediates in acid catalysed aquation reactions[4], and a fair number of pK_a values are available. Taking the proton as central ion there is a series of three complexes, $H^+ X^{x-}$, $H^+XM^{(x-m)-}$, $H^+XH^{(x-1)-}$, with stability constants defined by

$$K_{HX} = [HX^{(x-1)-}]/[H^+][X^{x-}] \quad (3a)$$

$$K_{H,XM} = [HXM^{(x-m-1)-}]/[H^+][XM^{(x-m)-}] \quad (3b)$$

$$K_{HXM} = [HXH^{(x-2)-}]/[H^+][XH^{(x-1)-}] \quad (3c)$$

It turns out that in most cases stabilities decrease in the order $K_{HX} > K_{H,XM} > K_{HXH}$ (that is, the hydrogen ion which is to be attached to X is repelled either by an existing metal ion, or by a hydrogen ion, but more so by the latter). Table 1, section *a*, gives some idea of the variety of metals and ligands which obey this rule, and section *b* of the Table shows that the same holds good (with one exception) in complexes with negative ligands already attached to the metal.

It might be expected that a small and highly charged metal ion would have a greater repulsive effect than the proton, but although this can happen it is quite rare. Examples (Table 1, section *c*) include manganese(IV) in certain complexes with tellurate ion, and the alkyl carbon atom when considered as a solvated "metal" in ions of the type $CH_3OH_2^+$ (the latter expressing the familiar fact that alcohols are less basic than water).

Similar comparisons can be made taking M^{m+} itself as central ion. The complexes are $M^{m+}{\cdot}X^{x-}$, $M^{m+}{\cdot}XM^{(x-m)-}$, $M^{m+}{\cdot}XH^{(x-1)-}$, with stability constants defined as

$$K_{MX} = [MX^{(m-x)+}]/[M^{m+}][X^{x-}] \quad (4a)$$

$$K_{MXM} = [MXM^{(2m-x)+}]/[M^{m+}][XM^{(x-m)-}] \quad (4b)$$

$$K_{M,XH} = [MXH^{(m+1-x)+}]/[M^{m+}][XH^{(m-1)-}] \quad (4c)$$

and by analogy with the previous results, the stability sequence is expected to be $K_{MX} > K_{MXM} > K_{M,XH}$, though again, with small and highly charged metal ions, the order might change to $K_{MX} > K_{M,XH} > K_{MXM}$.

Free Energies

The assumption now proposed is that in both series the repulsive effects of M^{m+} and H^+, expressed as free energies, are in the same ratio. In other words, the value of log K_{MXM} divides the interval (log K_{MX}–log $K_{M,XH}$) in the same ratio that log $K_{H,XM}$ divides the interval (log K_{HX} − log K_{HXH}).

$$\frac{\log K_{HX} - \log K_{H,XM}}{\log K_{HX} - \log K_{HXH}} = \frac{\log K_{MX} - \log K_{MXM}}{\log K_{MX} - \log K_{M,XH}} \quad (5)$$

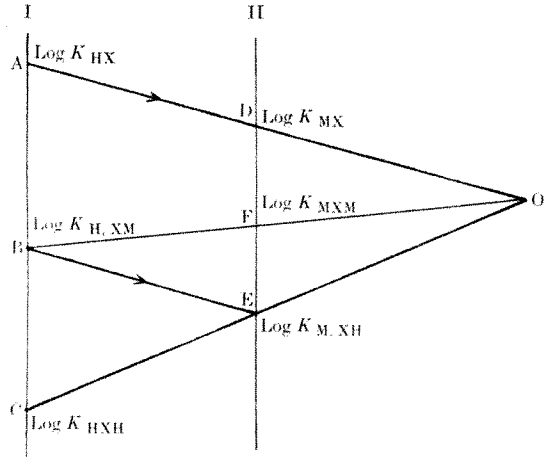

Fig. 1

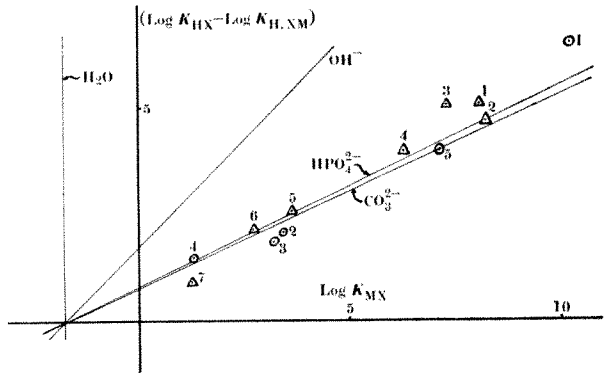

Fig. 2. Effect of coordinated metal ions M on the proton affinity of ligands X. △, Complexes of HPO_4^{2-}: 1, Al^{3+}; 2, Fe^{3+}; 3, $Al(H_2PO_4)_2^{2+}$; 4, $Al(H_2PO_4)^{2+}$; 5, $Co(NH_3)_5^{3+}$; 6, Ca^{2+}; 7, Sr^{2+}. ⊙, Complexes of CO_3^{2-}: 1, H^+; 2, Mg^{2+}; 3, Ca^{2+}; 4, Na^+; 5, $Co(NH_3)_5^{3+}$. Data from ref. 3.

and because, by definition,

$$K_{HX} \cdot K_{M,XH} = K_{MX} \cdot K_{H,XM} \quad (6)$$

this gives

$$\log K_{MXM} = \log K_{MX} - \frac{(\log K_{HX} - \log K_{H,XM})^2}{(\log K_{HX} - \log K_{HXH})} \quad (7)$$

Fig. 1 shows that the basic assumption is reasonable. On a vertical axis I, values of log K_{HX}, log $K_{H,XM}$ and log K_{HXH} are plotted as points A, B, C and on an adjacent parallel axis II, log K_{MX} is plotted as point D. From equation 6, a line through B parallel to AD gives E, corresponding to log $K_{M,XH}$. Let AD and CE meet at O. Then, if equation 5 is valid, joining OB gives F on line II corresponding to log K_{MXM}. The assumption is thus equivalent to saying that $MX^{(m-x)+}$ can be treated as a ligand and that there are linear free energy relationships between the stabilities of its complexes and those of the other ligands X^{x-} and $XH^{(x-1)-}$.

Equation 7 contains two independent variables, K_{MX} and $K_{H,XM}$, but in certain cases one of them can be eliminated. For a given ligand X^{x-} with a series of metals M^{m+}, it is suggested that the acidity of the H in $MXH^{(m+1-x)+}$ will be related to the stability of $MX^{(m-x)+}$. This is clearly to be expected if the bonding is predominantly electrostatic; but, if not, it can still be argued that a highly polarizing metal M^{m+} will take a disproportionate share of electrons and so weaken the X-H bond. Fig. 2 appears to support this assumption, and in the special case $X = OH^-$ we obtain a straight line relationship by definition. Taking

$$K_{MX} = [MOH^{(m-1)+}]/[M^{m+}][OH^-] \quad (8a)$$

and

$$K_{MXM} = [MOHM^{(2m-1)+}]/[MOH^{(m-1)+}][M^{m+}] \quad (8b)$$

the other equilibrium constants become

$$K_{M,XH} = a^{-1} \quad (9a)$$

$$K_{HX} = a/K_w \quad (9b)$$

$$K_{H,XM} = (K_w K_{MX})^{-1} \quad (9c)$$

$$K_{HXH} = a^{-1} \quad (9d)$$

where $K_w = [H^+][OH^-]$ and $a = [H_2O]$; and therefore

$$\log K_{HX} - \log K_{H,XM} = \log K_{MX} + \log a \quad (10)$$

which corresponds in Fig. 2 to a line of unit slope cutting the horizontal axis at log $K_{MX} = -\log a$. The further special case $X = H_2O$ gives a vertical line cutting the horizontal axis at the same point (that is, species $MOH_3^{(m+1)+}$ are expected to have varying acidities depending on the nature of M, but K_{MX} is always equal to a^{-1}). For complexes with monohydrogen phosphate ion the data are sufficient to suggest a linear relationship; for carbonate ion there are fewer points, but it is notice-

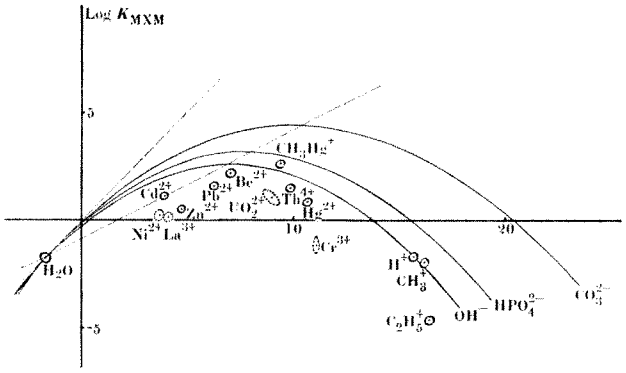

Fig. 3. Stabilities of complexes $M_2X^{(2m-x)+}$. The points are data for $X^{x-}\equiv OH^-$. A dotted line surrounding a point indicates approximate limits of error; a full line indicates that the limits of error are too small to be shown clearly. The curves are calculated from equation 13 and the straight lines have slopes 1 and ½.

able that in both cases the best straight line through the available points gives a negative intercept on the log K_{MX} axis. This suggests the general relationship,

$$\log K_{HX} - \log K_{H,XM} = \alpha(\log K_{MX} + \log a) \qquad (11)$$

where α is a constant depending only on the nature of X. In particular

$$\log K_{HX} - \log K_{HXH} = \alpha(\log K_{HX} + \log a) \qquad (12)$$

so that equation 7 becomes

$$\log K_{MXM} = \log K_{MX} - \alpha \frac{(\log K_{MX} + \log a)^2}{(\log K_{HX} + \log a)} \qquad (13)$$

Thus, as K_{MX} varies over a series of metals, K_{MXM} will pass through a maximum value

$$\log K_{MXM} = \left(\frac{1}{4\alpha}\right)(\log K_{HX} + \log a) - \log a = \log K_{MXM}^{max} \qquad (14a)$$

say at

$$\log K_{MX} = \left(\frac{1}{2\alpha}\right)(\log K_{HX} + \log a) - \log a = \log K_{MX}^{max} \qquad (14b)$$

then

$$(\log K_{MXM}^{max} + \log a) = \tfrac{1}{2}(\log K_{MX}^{max} + \log a) \qquad (15)$$

independently of the nature of the ligand.

Using these equations, curves predicting log K_{MXM} for different metals and ligands are shown in Fig. 3. Geometrical features of the diagram are that all maxima fall on the line defined by equation 15, and all curves pass through a common point with unit slope. The common point can be assigned to the "metal" H_2O, with log K_{MX} = log K_{MXM} = − log a. With carbonate ion as ligand, maximum stability of the bridged binuclear complex is expected to occur when K_{MX} is of the order of 10^{11} M^{-1}, but unfortunately most of the stability constants so far reported[3] are considerably less than this and it seems doubtful whether the predicted turnover in log K_{MXM} will be verified experimentally. A similar difficulty arises with the monohydrogen phosphate ion, though log K_{MX}^{max} is appreciably lower and given a sufficient number of experimental results some curvature might become apparent. For hydroxide ion, however, there is a fairly extensive series of data, and with the special values (equations 9) of the equilibrium constants, equation 7 becomes

$$\log K_{MXM} = \log K_{MX} - (\log K_{MX} + \log a)^2 / (2 \log a - \log K_w) \qquad (16)$$

predicting a maximum log k_{MXM} at log $K_{MX} = \frac{1}{2}\, pK_w \cong 7{\cdot}0$, well within the range of reported values.

The hydroxide data are entered in Fig. 3. Wherever possible, values of K_{MX} and K_{MXM} are taken from studies[3,5] in which both MOH and M_2OH were detected in the same medium, and limits of error are those suggested by the authors. The data for Be^{2+} are probably the most reliable of any. At least seven independent studies[6–12] confirm the existence of Be_2OH^{3+} and all but one[11] are agreed on the absence of $Be_2(OH)_2^{2+}$ under the conditions of the experiments. The difficulty at first was to establish the stability of the mononuclear species. Mattock[6] postulated $BeOH^+$ with log $K_{MX} = 7{\cdot}3$ in 1 M $NaClO_4$, and Kakihana and Sillén[7] invoked $Be(OH)_2$ with log $\beta_2 = 17{\cdot}5$ in 3 M $NaClO_4$, but Mesmer and Baes[12] have shown that species of this basicity are more probably polymeric. Schwarzenbach, however, had obtained log $K_{MX} = 8{\cdot}2$ in 0·1 M $NaClO_4$, in rapid reaction conditions and free from polymerization[13], and recalculation of the original data of Kakihana and Sillén has also given[14] the upper limit log $K_{MX} \leqslant 8{\cdot}1$ which (allowing for the different ionic media) is consistent with Schwarzenbach's value. The converse situation arose with chromium(III). The monomer $CrOH^{2+}$ has been studied many times[3] by conventional methods, but the singly bridged dimer is always metastable towards other species. It has now been prepared separately, however, and its stability obtained from kinetic studies[15]. Data[16,17] for $PbOH^+$ and Pb_2OH^{3+}, and[18,19] for $ThOH^{3+}$ and Th_2OH^{7+}, also came from different sets of experiments, but only because stabilities of monomer and dimer necessitated different concentration ranges of total metal ion. With UO_2^{2+}, polynuclear complexes, and $(UO_2)_2OH^{3+}$ in particular, are well established, but mononuclear $(UO_2)OH^+$ is a very minor constituent and its stability has only been roughly estimated[20]. Because the authors report an overall formation constant for the binuclear ion, log K_{MXM} depends partly on log K_{MX} and the "point" for UO_2^{2+} in Fig. 3 is a straight line of slope minus one.

The point for $C_2H_5^+$ refers to equation 17*c*, calculated as follows:

$$2C_2H_5OH(g) \rightleftharpoons (C_2H_5)_2O(g) + H_2O(g) \qquad (17a)$$

$$2C_2H_5OH(aq) \rightleftharpoons (C_2H_5)_2O(aq) + H_2O(aq) \qquad (17b)$$

$$C_2H_5OH_2^+(aq) + C_2H_5OH(aq) \rightleftharpoons (C_2H_5)_2OH^+(aq) + H_2O(aq) \qquad (17c)$$

Kabel and Johanson[21] determined the thermodynamic equilibrium constant of reaction 17*a* in the gas phase at 120·8° C (compare with ref. 22). Heats of combustion of ethanol[23] and diethyl ether[24] give $\Delta H^\circ = -5{\cdot}55$ kcalorie mole^{-1} at 25° C, and from the variation of C_p with temperature for gaseous ethanol[25], ether[26] and water[25], $\Delta G^\circ = -2{\cdot}68$ kcalorie mole^{-1} in the gaseous phase at 25° C. Equilibria of ethanol and ether between the gaseous and dilute aqueous phases were measured by Butler[27] and together with the free energy of evaporation of liquid water[25], these data yield $\Delta G^\circ = +2{\cdot}84$ kcalorie mole^{-1}, or log $K = -2{\cdot}08$ for equation 17*b*. The thermodynamic pK_a of protonated diethyl ether is reported as $-3{\cdot}59$[28]; for protonated ethanol no value is available, but for protonated methanol and *n*-butanol $pK_a = -2{\cdot}5$ and $-2{\cdot}3$ respectively[28]. These values seem typical of the respective functional groups, and there is little doubt that ethers are less basic than the corresponding alcohols by about one pK unit. Log $K \cong -3$ for equation 17*c*, and log $K_{MXM} \cong -4{\cdot}7$.

Diethyl ether is apparently the only ether for which this calculation can be carried out in full, but a fairly confident estimate can be made for dimethyl ether. Published free energy data[25] yield $\Delta G^\circ = -4{\cdot}21$ kcalorie mole^{-1} for the reaction corresponding to equation 17*a*. The free energy of hydration is not known, but for diethyl, di-*n*-propyl, and ethyl-*n*-propyl ethers, Butler[27] found it to be almost the sum of those for the two corresponding alcohols (actually less, by $0{\cdot}17 \pm 0{\cdot}04$ kcalorie mole^{-1}).

Assuming that the same is true for dimethyl ether, we obtain log $K = +1{\cdot}0$ for the reaction corresponding to equation 17*b*, so that[28] log $K_{MXM} \simeq -2{\cdot}0$.

All the data (except for $C_2H_5^+$, CH_3^+ and H^+) relate to high ionic strengths, and the appropriate values of log K_w vary from $-13{\cdot}7$ to $-14{\cdot}2$; the concentration of water also varies, but for convenience the curve in Fig. 3 is calculated from equation 16, using log $K_w = -14{\cdot}0$, and $a = 55{\cdot}5$ M.

It was stated previously[29] that, with the exception of Be^{2+}, values of K_{MXM} do not vary greatly from one metal to another even though K_{MX} varies over eight orders of magnitude, and that a value of log $K_{MXM} = 0{\cdot}0 \pm 1$ would cover most M_2OH complexes. This is still true, but it also seems that there is a relationship between K_{MXM} and K_{MX}, and that a maximum in log K_{MXM} occurs somewhere near the middle of the series. (Although the scatter is large, it can be pointed out that the points which for various reasons can be considered most reliable are by themselves sufficient to indicate a strongly curved dependence of log K_{MXM} on log K_{MX}. These are the reference point (H_2O) and the data for Cd^{2+}, Be^{2+}, CH_3Hg^+, Hg^{2+}, Cr^{3+}, H^+ and $C_2H_5^+$.)

Although the points follow the shape of the calculated curve fairly well, most of them lie significantly below it. Neglect of ionic strength effects may be one reason for this, but other correlations can also be pointed out. For example, the ions closest to the curve include those with the smallest radii (or alternatively those with lowest coordination number with respect to the solvent). Schwarzenbach[5] has particularly emphasized the analogy between CH^3Hg^+ and H^+, both having a coordination number of 1.

A non-linear relationship between the stability of mono and binuclear complexes was predicted by Martell[30] for dihydroxodimers of the form $LM(OH)_2ML$, where L is a non-bridging polydentate ligand. Martell pointed out that up to a certain point, increasing the nuclear charge of M would increase the stability of the dimer, but beyond that point repulsion between the two metal ions would become more important.

Simple Ionic Model

It is interesting to note that a simple ionic model leads to a relationship of the same form as equation 13. Assigning radii r_m and r_x, and effective charges $+z_m e$ and $-z_x e$ to metal and ligand respectively, the coulombic interaction energy in the mononuclear complex MX is given by

$$U_{MX} = -z_m z_x e^2/(r_m + r_x) \qquad (18)$$

Introducing a second metal ion M, with bond distances unchanged, and M-X-M bond angle 2θ, the additional coulombic terms are given by

$$U_{MXM} = z_m^2 e^2/2(r_m + r_x) \sin\theta - z_m z_x e^2/(r_m + r_x) \qquad (19)$$

$$= U_{MX} + (r_m + r_x) U_{MX}^2/2 z_x^2 e^2 \sin\theta \qquad (20)$$

For a series of complexes with constant r_m, variation in stability can be attributed to variation of z_m, and there is a maximum U_{MXM} when

$$z_m/z_x = \sin\theta \qquad (21)$$

$$U_{MXM} = -z_x^2 e^2 \sin\theta/2(r_m + r_x) \qquad (22)$$

$$= \tfrac{1}{2} U_{MX} \text{ (compare equation 15)} \qquad (23)$$

On the other hand, for a series of complexes in which r_m and z_m both vary, but U_{MX} remains constant, U_{MXM} is expected to become less negative with increasing r_m:

$$U_{MXM} = U_{MXM}^{\circ} + (U_{MXM}^{\circ} - U_{MX}) \frac{r_m}{r_x} \qquad (24)$$

where U_{MXM}° is the value of U_{MXM} corresponding to $r_m = 0$. Similar considerations apply when the ligand X is polyatomic, and the two metal ions are attached at different points. Thus the gaseous ionic model correctly predicts both the occurrence of the maximum stability, and the scatter of points according to ionic radii. On the other hand, it is certainly not realistic, for it predicts $z_m/z_x = 0{\cdot}87$ to $1{\cdot}0$ (taking θ from 60° to 90°), and total energies in the gas phase bear little relation to free energies in solution; a more detailed treatment would involve consideration of ion-solvent interactions.

Another factor is repulsion between non-bridging ligands[32,33]. This may be important with ions such as La^{3+}, if the positive charge is effectively delocalized on to the coordinated water molecules, or with Cr^{3+} in view of the well known rigidity of the octahedral structure. The difference in stability between methyl and ethyl ethers can also be attributed to steric effects, because it is equally pronounced in both gaseous and aqueous phases.

It must be emphasized that these arguments apply only when all four species MX, MXM, MXH, HXH have analogous structures. For instance, if X is a multidentate ligand giving a chelate MX, a relationship of the type of Fig. 3 may exist, but it can be shown that K_{MXM} will always be lower than the prediction of equation 13 by a factor depending on the magnitude of the chelate effect for the ligand in question. In a number of cases the acid H_2X is known or believed to have both protons attached to the same atom of X, whereas in M_2X this is precluded by steric factors. In such cases, only an upper limit can be obtained for the value of log K_{HXH}, and equation 5 can no longer be used.

Crystal Structures of $[(CO)_3OsO]_4$ and $[(C_2H_5)_3PtCl]_4$ and a Discussion of Known and Possible Related Tetrameric Compounds

Compounds with a cubane skeleton are found in nearly every group of the periodic table. The structure of two of these compounds has been determined.

RECENT X-ray diffraction studies in these laboratories have enabled us to determine the structure of the two compounds $[(CO)_3OsO]_4$ (ref. 1), Fig. 1, and $[(C_2H_5)_3PtCl]_4$ (ref. 2), Fig. 2; both of these are similar to the tetrameric "cubane—Type I" structure of Fig. 3 with an octahedrally coordinated metal atom and a trigonal ligand. ("Cubane", C_8H_8, has a structure in which there are eight C–H groups at the corners of a cube, Fig. 4 (ref. 3).)

The osmium compound is obtained in small yield in the preparation of $Os_3(CO)_{12}$ from OsO_4 and carbon monoxide in xylene[4,5]. The platinum compound was synthesized by Kettle[6]. Both structures are similar to that of $[(CH_3)_3PtCl]_4$ (Fig. 3, Type I, M=Pt, X=Cl, L=Me) reported some years ago[7]. This similarity and the fact that Os(II) and Pt(IV) are isoelectronic caused us to consider whether this structure is widespread for the other isoelectronic metals (W(0), Re(I) and Ir(III)) in the sequence. In fact, the compound $[(CO)_2(NO)Mo(OH)]_4$ (ref. 8) is formally of this type if one assumes that the NO group acts as a uni-positive radical with OH being the negative radical; this is of Type I with one NO and two CO groups on each metal atom.

Re(I) and Mn(I) of group VII form compounds $[(CO)_3M(I)SR]_4$ which were shown[9] by infrared spectroscopy to have structures with cubic symmetry. So far, no compounds of this type have been reported for the triad Co^{III}, Rh^{III} and Ir^{III}; in Table 1 we summarize examples of known compounds with the skeleton depicted schematically in Fig. 3. The metal may be 3, 4 or 6-coordinated.

In the transition metal series considered so far the metal has a d^6 configuration with low spin. Some of the compounds crystallize with $\bar{4}3m$ symmetry for the molecule while in others it approximates to this symmetry, although this is not a crystallographic requirement. For these compounds the general formula may be written $[L_3MX]_4$. For non-transition elements, however, the same MX skeleton with the same symmetry is found, although the general formulae correspond to $[MX]_4$ or $[LMX]_4$. A particularly interesting example is the non-metal compound "cubane" itself. The geometrical similarity between "cubane" and alkoxides and alkyl-amides such as MeZnOMe[10] (Fig. 5), TlOMe[11] (Fig. 6) and PhAlNPh[12] was pointed out by Tzschach and Balszuweit[13].

In Table 1, X covers a wide range of entities. It may be uni-negative Cl^-, I^-, OH^-, OR^-, SR^- or bi-negative O^{2-}, S^{2-}, NR^{2-}; it is even possible to describe $[PhSnP]_4$ formally in terms of a tri-negative P^{3-} and tri-positive $PhSn^{3+}$ but the ionic picture is no longer applicable to cubane itself (Fig. 4) in which each CH group forms three single bonds to other groups. In his review of polymers formed by alkoxo and alkyl-amido bridges, Bradley[14] considered that the number of bonds possible

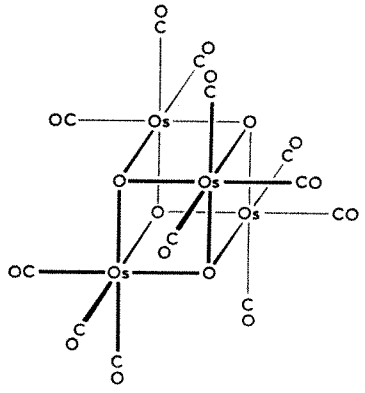

Fig. 1. The structure of $[(CO)_3OsO]_4$, tetra-μ_3-oxotetrakis[tricarbonylosmium (II)]. In this, as in most of the diagrams, the structure shown is idealized. As discussed in the text, the angles at the corners of the "cube" are not necessarily 90°.

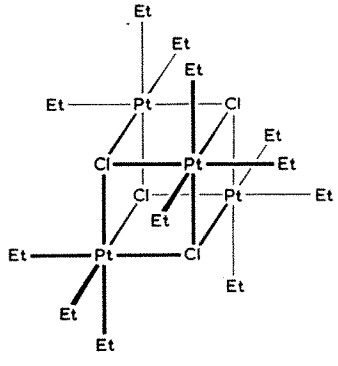

Fig. 2. The structure of $[Et_3PtCl]_4$, tetra-μ_3-chlorotetrakis[triethylplatinum (IV)].

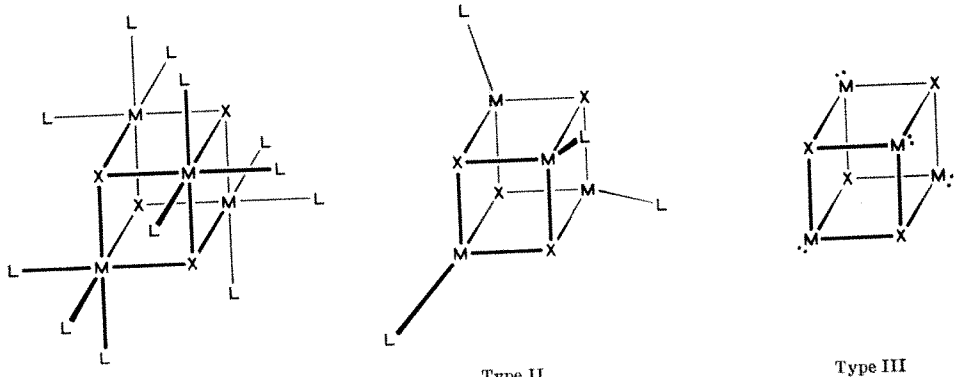

Fig. 3. Cubane-like structures. Type I, L_3MX, metal atom M, octahedral. Type II, LMX, metal atom M, tetrahedral. Type III, MX, metal atom M, trigonal. (In all cases X may be tetrahedral, for example, CH_3O^-; or pyramidal, for example, I^-.)

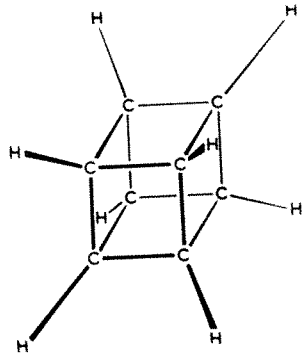

Fig. 4. The molecule of "cubane", C_8H_8.

was equal to the number of lone pairs available, that is, three in the uni-negative ions. Our description of L_3M, LM or M in Table 1 in terms of the number of electrons is based implicitly on an ionic model for alkali metals, for aluminium, and for the transition metals where the anionic entity is uni- or bi-negative. For the elements with d^{10} electron shells there are $[Me_3AsCu^+I^-]_4$ (ref. 15) (Fig. 7) in group IB and many examples of $[LMX]_4$ for group IIB where M is Zn, Cd or Hg (ref. 14), all of which may be reasonably written in the ionic form. For the compounds of Tl(I) and Pb(II), the neutral thallium alkoxides and the charged $[PbOH]_4^{4+}$, one may postulate a cation with a lone pair of electrons occupying the corner, as shown in Fig. 6. Recent calculations[16] indicate that less than 0·1 of an electron is involved in the metal–metal bonding postulated to explain the high intensity of the low-frequency Raman bands.

There is a lack of X-ray diffraction measurements on these interesting heavy metal compounds. In the only one studied in the crystalline form with the empirical formula TlOMe, a tetrahedron of thallium atoms was found[11] although no atoms of the methoxyl groups were located. Similar tetrahedra of metal atoms have been found in solutions of other thallium alkoxides[17] and of $[PbOH]_4^{4+}$ (ref. 18). For PhSnP the bonding is presumably covalent with sp^3 hybridized tin being bound to one phenyl group and three trivalent phosphorus atoms. The dimensions of this molecule are not known, the evidence[19] in support of the proposed tetrameric structure being the cryoscopic molecular weight and the infrared spectrum which is consistent with high symmetry. In addition to the possible electrostatic, covalent and metal–metal bonding mentioned, the "cubane" structure is also found with electron deficient bonding in lithium methyl[20]. Here X ($=CH_3^-$) has only one lone pair of electrons so it must form three electron-deficient bonds. Ironically the first reported compound with a methyl group acting in this way, $[(CH_3)_3PtCH_3]_4$, which led to the late R. E. Rundle's excellent work on electron-deficient compounds, has since been shown to be $[(CH_3)_3PtOH]_4$ (ref. 21).

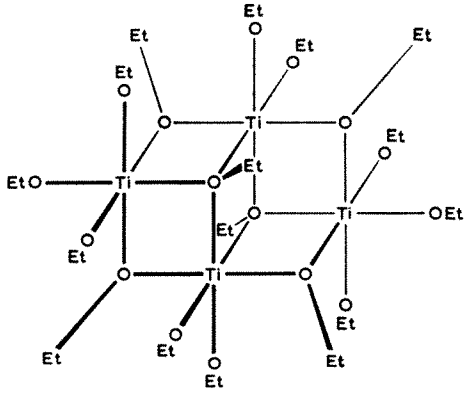

Fig. 8. Titanium ethoxide tetramer.

The compounds can be considered as tetrahedra of four M atoms with X in a position along the normal at the centre of a face of the tetrahedron. If X were at zero distance along the normal it would lie in the face and M–X–M would be 120°. If the distance along the normal is 0·409 times the metal–metal distance the angles M–X–M and X–M–X would both be 90°, that is, the ideal "cube". Greater distances can lead to a description in terms of X being "above the faces of the tetrahedron". If the distance along the normal is very long there is presumptive evidence of metal–metal bonding. Comparison of M–X with M–M gives the simplest criterion, M–X = 0·433 × M–M for X in the face of the tetrahedron; MX = 0·707 M–M for the ideal cube, and M–X > 0·707 M–M for a tetrahedron with X above the faces.

For the d^6 metals M–X ≈ 0·65 M–M in trialkyl platinum compounds[2,7] this corresponds to angles of 80° at Pt and 100° at X, in both cases 10° smaller than the ideal octahedral and tetrahedral angles respectively. Potassium tertiary butoxide (K–O = 0·707 × K–K) is described as having an "only slightly distorted cubic" structure[22,23]; PhAlNPh is similar[12] but the Li–C distance[20] is 0·89 × Li–Li in the electron-deficient $LiCH_3$ and this may indicate some Li–Li bonding. Similar evidence, that is, Cu-I = 1·02 × Cu-Cu, giving an acute angle at iodide[15], suggests metal–metal bonding in the d^{10} compound. In the Zn(II) compound[10], MeZnOme, however, Zn-O = 0·66 × Zn-Zn so that the acute angle is at the metal. This is distorted more from a tetrahedron than is the oxygen.

We should point out that there are compounds which might be expected to have this structure but do not; for example, titanium ethoxide could be written $[(EtO)_3TiOEt]_4$ but actually has the arrangement[24] shown in Fig. 8. There are also compounds which have the MX skeleton without forming part of our series, for example, [salicylaldehydato(ethanol)nickel(II)OMe]$_4$ (ref. 25) (Fig. 9).

Another series of compounds containing one set of atoms, M, at the corners of a tetrahedron have six, not four, groups joining them so that the bridging groups occupy the edges of the tetrahedron. For group IV these include the covalent compound adamantane $(CH)_4(CH_2)_6$ and compounds which may have some ionic character for d^0, $(MeSi)_4S_6$ (Fig. 10) and for d^{10}, $(MeSn)_4S_6$ (ref. 26). In group V compounds of this shape correspond to M(III) and may have a lone pair of electrons in the fourth position, for example, hexamethylenetetramine and $As_4(NMe)_6$ (Fig. 11)[27]. In the transition metal series a compound $(R_3PNi)_4(CO)_6$, where $R = C_2H_4CN$, has been found[28] with this geometry; the >C=O groups are bridging and Ni–Ni bonding is also postulated to complete a close-shell configuration.

Finally, we consider extending the series of compounds for transition metals. The simplest method is a small change from a known one, for example, $[(CO)_3OsNR]_4$ prepared with NR^{2-} instead of O^{2-}. Next we try to find isoelectronic metals; for Co, Rh, and Ir the d^6 configura-

tion is obtained for the oxidation state III; if L is neutral as in CO, then X must be N or P. Reduction of symmetry requirements by allowing, as in the Mo compound, for different L groups gives greater flexibility. We can, for example, postulate $[Cl_2COIrCl]_4$, $[Cl(CO)_2IrO]_4$ or $[(CH_3)_2COIrI]_4$.

The Earliest Known Record of a Solar Eclipse

by
F. R. STEPHENSON
Department of Geophysics and Planetary Physics,
University of Newcastle upon Tyne

One of the Ugaritic texts of the Second Millennium BC describes a total eclipse of the Sun. The date is established as 1375 BC, May 3.

THE excavations of ancient Ugarit, begun in 1928, have revealed numerous clay tablets of great literary interest. Their discovery has been as revolutionary in the field of biblical studies as the discovery of the Dead Sea Scrolls. From archaeological evidence the texts date from the period 1450–1200 BC. They are written in a cuneiform script which is the earliest alphabetic script as yet deciphered.

Only one of the texts so far published is of an astronomical nature; this describes a solar phenomenon. A photograph of one side of the tablet, called side *A*, is shown in Fig. 1. A recent translation of the inscription on both sides of the tablet is given by Sawyer[1] as follows:

Side A: The day of the new Moon in the month of Hiyar was put to shame. The Sun went down (in the daytime) with Rashap in attendance.

Side B: (This means that) the overlord will be attacked by his vassals.

The absence of any parallel to this text in the Ugaritic literature suggests that the phenomenon was rare and spectacular, and the description can hardly refer to anything other than a total eclipse of the Sun. Numerous accounts of total solar eclipses are to be found in mediaeval European and Far Eastern literature. These leave no doubt that the sudden and intense darkness, appearance of stars, and other phenomena which accompany the complete disappearance of the Sun produced a profound impression on the observers. In contrast, annular and large partial eclipses attracted little interest. Few descriptions of total eclipses survive from before the Christian era, but we should expect such records to be found in areas where a sufficiently representative bloc of literature is extant.

The archaeological evidence allows the date of the event (hereafter regarded as a solar eclipse) to be fixed only between about 1450 and 1200 BC. It cannot have occurred later than this, for the city was destroyed by invaders about the year 1200 and was never rebuilt. The inscription states that the phenomenon occurred on the day of the new Moon in the month of Hiyar. Hiyar, the second month of the year, corresponds to about April–May. Total eclipses of the Sun are rare at a given place, occurring on average about three times in a millennium; this suggests that a definite date for the event can probably be established.

Accurate computation of an ancient solar eclipse for a given place is limited by the non-uniformity of the Earth's rotation and the tidal recession of the Moon from the Earth. Irregularities in the Earth's rotation are chiefly the result of tides, but other causes are changes in sea level and electromagnetic coupling between the core and mantle of the Earth. A computation of a solar eclipse which ignores these effects may be in error by up to about 4 h in time and 50 per cent in phase near 1300 BC. The most convenient method of analysis is to assume that the Earth rotates uniformly and to make corrections to the mean longitudes of the Sun and Moon from a study of

reliable records of astronomical events in history. These observations are themselves mainly of total eclipses of the Sun, for which the production of an accurate record makes the minimum of demands on the observer. The earliest of these records dates from 709 BC (China). By extrapolation, it is expected that errors in the computation of the Ugaritic eclipse do not exceed 1 per cent in the magnitude and 5 min in the time of occurrence.

The four dates in the table were selected from a computer analysis of about 500 solar eclipses which occurred on the Earth's surface during the period covered by the texts. The program required only the input of the geographical coordinates of the city of Ugarit (35° 37′ N, 35° 47′ E) and the Julian day number for each eclipse. Apart from the four eclipses in the table, no generally total eclipse reached a phase of greater than 88 per cent at the capital. The few annular eclipses during this time would not produce appreciable darkening of the daylight.

It is clear that only the eclipse of 1375 BC May 3 could have occurred in the month of Ḫiyar. This was total near the northern boundary of the Kingdom of Ugarit (see Fig. 2). There appear to be no records of the other eclipses in the table. The loss of daylight in 1340 BC and 1223 BC would probably be too small in Ugarit to attract attention there, but the eclipse of 1406 BC must have been very spectacular. Much of Ugarit has still be excavated, and it seems possible that a reference to this may yet turn up.

The period close to 1375 BC was one of great literary activity in Ugarit and it is not surprising to find a description of the eclipse of 1375 BC. Although the estimated uncertainty in the position of the belt of totality (about 30 km) does not make the eclipse quite complete at the capital, it would have been extremely striking in the northern part of the kingdom and may well have been total there. The reference to Rashap (= Mars) is interesting. Calculation shows that on the morning of May 3, 1375, Mars was below the horizon. Both Aldebaran and Capella, however (the latter of which was called "red" by Ptolemy and other early astronomers), were near the darkened Sun and either star may have been mistaken for Mars.

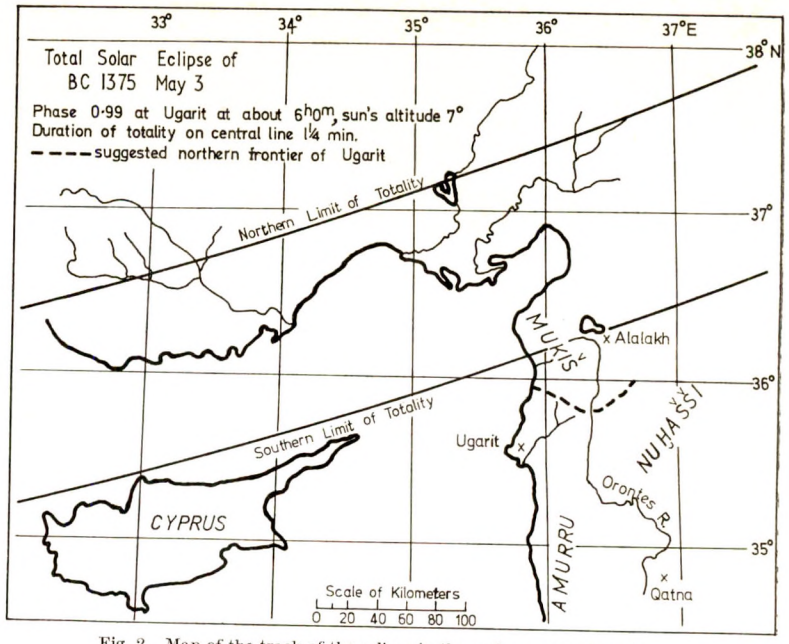

Fig. 2. Map of the track of the eclipse in the region around Ugarit.

Table 1. COMPUTED CIRCUMSTANCES FOR THE TOTAL SOLAR ECLIPSES VISIBLE NEAR UGARIT FROM 1450 TO 1200 BC

Date BC	Magnitude at Ugarit	Local time h	Local time min	Sun's altitude degrees	Zone width km	Total time min	Total time s	Position of central zone
1406 July 14	>100	15	30	43	180	3	30	Total at Ugarit
1375 May 3	99	6	00	7	130	1	15	55 km N of Ugarit
1340 Jan. 8	96·5	11	05	29	320	3	30	240 km N of Ugarit
1223 Mar. 5	96	13	25	40	170	3	30	165 km N of Ugarit

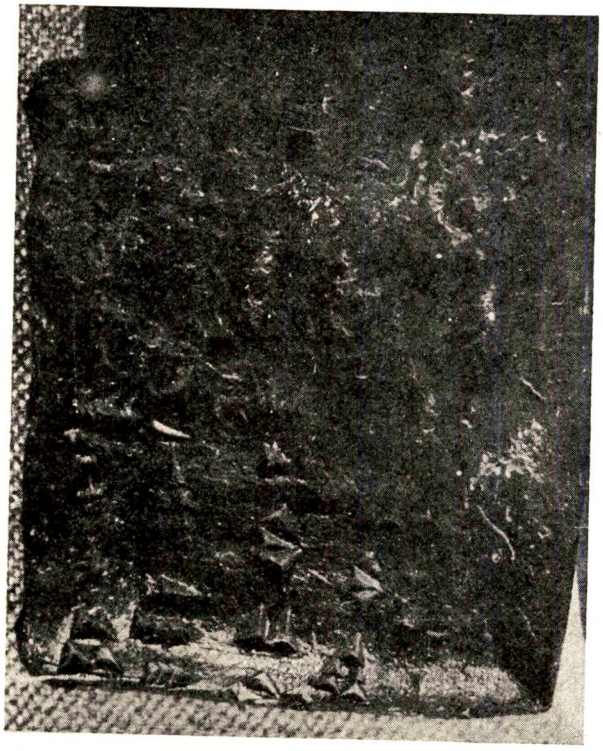

Fig. 1. One side of the tablet with text describing a solar phenomenon.

The importance of the eclipse of 1375 BC is two-fold. It is of considerable value in Ugaritic chronology, for its date is the first definite date to be established. The record probably implies that the eclipse was total within the boundaries of the Kingdom of Ugarit. As these can be fixed with a fair degree of confidence, the eclipse could prove useful in the study of the Earth's rotation.

The only known observation of a solar eclipse of comparable age to that made in Ugarit is the one recorded on one of the oracle bones found in Anyang, N. China[2,3]. It has been deciphered as reading: "Three flames ate the Sun and a great star was seen". Liu Chao-yang has put the date of the event as the late fourteenth or early thirteenth century BC. Computation shows that between 1400 BC and 1200 solar eclipses were total near Anyang only in 1370, 1330, 1304, 1250 and 1230. If the record is authentic, and indeed describes a complete eclipse of the Sun, the observation should have been made in one of these years. Precise identification of the eclipse, however, must await further work on Shang dynasty chronology. The solar eclipse observed in Ugarit on the morning of May 3, 1375 BC, would appear to be the earliest for which there is a record.

Ionospheric Electron Concentration Enhancement during a Solar Flare

DURING solar flares, sudden increases of extreme ultraviolet (EUV) and X-ray flux produce abrupt increases of electron concentration (N_e) in the sunlit part of the ionosphere. Because of their relatively short duration and the accompanying blackout in h.f. propagation, these enhancements of N_e have hitherto been difficult to investigate, especially in the E region. We report here some results of applying a new technique, incoherent scatter radar, to this problem. The observations were made at Malvern (52·1° N, 2·3° W) during a solar flare on February 20, 1970.

The equipment used was a pulsed vertically pointing radar operating at a frequency of 400·5 MHz, with a transmitted pulse length of 33 μs (5 km radar length). Scattered signal power was measured in ninety consecutive range sampling intervals, each 3 km wide, spanning the altitude range from 50 km upwards. Adequate precision was achieved by integrating the signals for periods of 5 min. The measurements were converted from scattered power to profiles of N_e against height by normalizing at a height of 110 km to N_mE measured at Slough (130 km from Malvern). The assumption that the scattering cross-section per electron is independent of height is valid except below 95 km, where corrections for a finite plasma Debye length have been applied, and above 140 km, where the cross-section becomes a function of τ, the electron to ion temperature ratio. Because the mode of operation does not allow τ to be measured, the latter correction has not been applied; this does not, however, affect the conclusions of this communication. Below 90 km, the signals are contaminated with intermittent coherent echoes from aircraft in the aerial sidelobes; only uncontaminated data have been used, but the results are less reliable than at greater heights. Further details of the equipment and data processing are given in refs. 1–3.

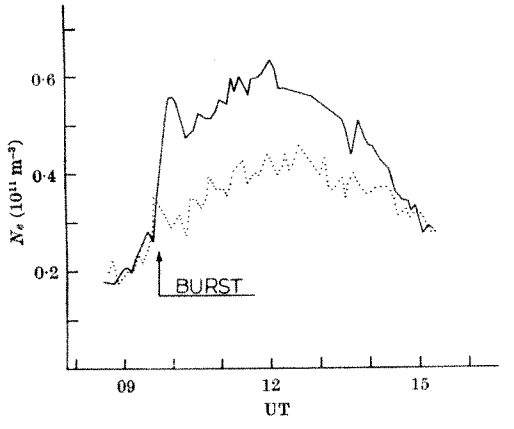

Fig. 1. Variations of Ne with time at height 96 km, on February 19 and 20, 1970. Time of start of radio burst is shown. · · · · , February 19; ———, February 20.

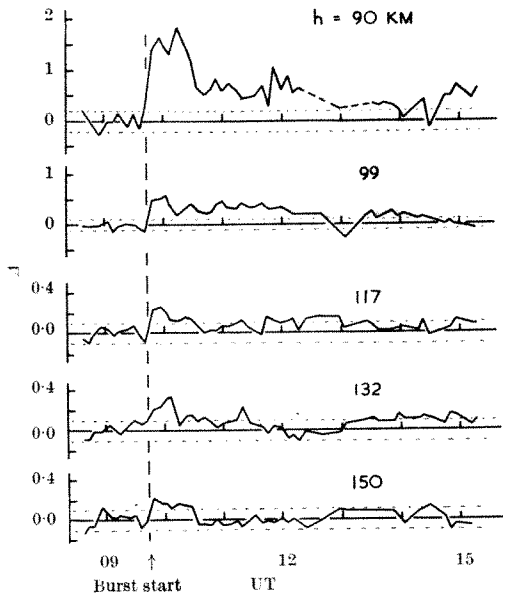

Fig. 2. Temporal variations of enhancement in N_e at five heights on February 20. Dashed lines are a conservative estimate of the baseline uncertainty.

The Hα flare on February 20, 1970, had an importance of at least 1*b*, with heliographic coordinates about 18° S, 32° E (McMath plage region 10584) and lasted at least 1 h[4]. The associated 10·7 cm radio burst observed at Slough[6] started at 0943 UT and peaked at 0944 UT. It was classified as a "great" burst, having a peak flux density of more than 500 flux units. There was an increase of flux density after the burst lasting about 3 h. A strong increase of X-ray flux was observed by the Explorer 37 satellite[5], which peaked in the 50–300 pm band at about the same time as the radio burst, and somewhat later at longer wavelengths. The X-ray flux was above normal until at least 1320 UT. The resulting sudden ionospheric disturbance, which was rated with importance 2+, was most intense at 1000 UT and ended at 1350 UT[5].

At all heights up to 150 km, the incoherent scatter measurements showed a rapid increase of N_e at the start of the disturbance, reaching a maximum between 0950 and 1000 UT. The magnitude and duration of the enhancement varied with height. As an example, plots of N_e against time for a height of 96 km on the flare day, February 20, and the previous day, February 19, are shown in Fig. 1. The problem of measuring the magnitude of a change in N_e is basically that of knowing what N_e would have been in the absence of the flare. On February 19, N_e at 96 km shows a regular diurnal variation with quasiperiodic fluctuations superimposed. The regular variation repeats well from one undisturbed day to the next, but the fluctuations are unpredictable. We have calculated the fractional deviation, Δ, of N_e on February 20, where

$$\Delta = (N_e - N_{eo})/N_{eo}$$

and N_{eo} is a smoothed reference value measured at the same time on February 19. Thus plots of Δ against time show the effects of irregular variations on both days, and also systematic changes due to the flare.

Fig. 2 shows the variations of Δ at five different heights ranging from 90 to 150 km. Dashed lines indicate a

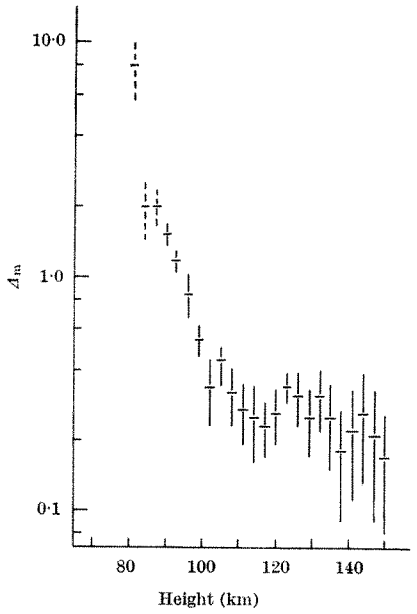

Fig. 3. Variation of the peak enhancement, Δ_m, with height. Values at the lowest heights are somewhat less reliable than the remainder. Baseline uncertainties are included in the error bars.

conservative estimate of the maximum uncertainty in the zero level obtained from measurements taken on two other consecutive pairs of undisturbed days in winter. At 90 km there is a large enhancement of N_e, lasting for at least 3 h, whereas at 132 and 150 km there are only marginally significant enhancements, which probably do not last longer than about an hour. It should be noted that the measurements are effectively 5 min running averages, so that variations on a time scale of a minute or so, such as may have occurred at the start of the disturbance, are inadequately depicted.

Fig. 3 shows the variation with height of the maximum enhancement, Δ_m, measured about 10 min after the start of the event. Values of Δ_m below 90 km are somewhat uncertain, partly because of the coherent echo problem, and partly because N_e on the control day was near the noise level. It is probable that enhancements approaching an order of magnitude are found at the bottom of the E region, and thus large increases in nondeviative absorption of h.f. waves must occur.

Somewhere below 100 km, solar X-rays become the chief source of photoionization in quiet conditions, with an uncertain contribution from HLyα[7]. It is thus significant that both the agreement between the time histories of the ionospheric and X-ray events and the height variation of the N_e enhancement point to X-rays as the main cause of the terrestrial flare effects. It is also interesting to see that the decimetric radio flux was a better indicator of the magnitude and duration of the ionospheric effects than were the Hα flare data.

Six Minute Periodicity during X-ray Flares

The satellite OSO-IV, launched on October 18, 1967, carried a group of detectors to observe the soft X-ray emission from the Sun[1], Fig. 1 shows sample time profiles of the emission during flares as observed with a detector sensitive in the wavelength band 0·1 to 0·3 nm. In each case the time scale is the same but the intensity scale has been adjusted to show the full range of values during each event. During the visible class 1N flare represented in Fig. 1*a*, the X-radiation reached two peaks, the maxima being 6 min apart. Further evidence of such a time period is shown in Fig. 1*b* where the initial activity is considerably smaller than the second peak of the flare. Flares of this type have been noted by Teske[2] and by Culhane and Phillips[3]; the initial event has been called the precursor to the main event. It is suggested here that the precursor is really a part of the main flare activity, but that unlike the increase in Fig 1*a* the initial development is relatively small compared with the second increase. Indeed, further evidence that this is the case seems to be provided by Fig. 1*c*. In this case there is a minor increase in X-ray flux about 6 min after the main increase. If the relative intensities of the two increases had been different, the first peak might have been called the precursor.

Because the X-ray detector monitored the flux from the whole solar disk, there was no indication of the location of each flare event. Information has been obtained from solar geophysical data on the location of

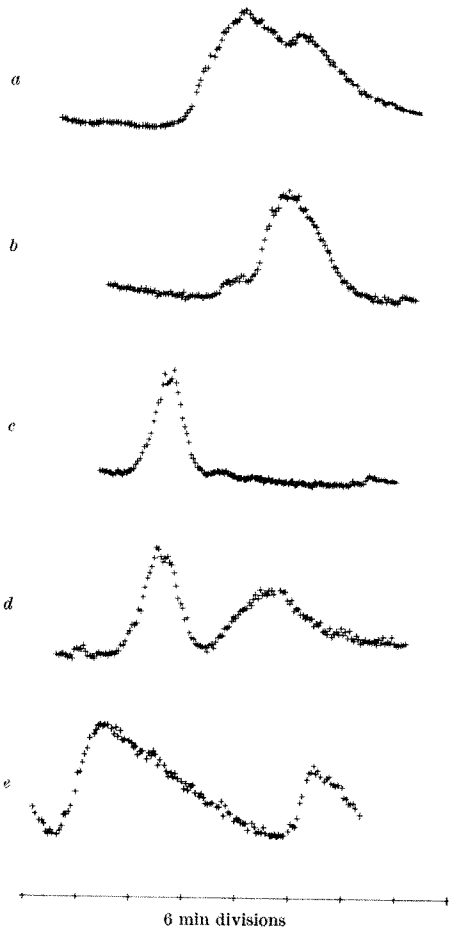

Fig. 1. Time profiles of X-radiation (0·1–0·3 nm) observed during selected flares. The linear intensity scale in each case has been chosen so that the complete profile can be presented. The time scale intervals are 6 min. (Time periods should be measured between points at which the rate of flux increase becomes relatively small.)

activity, and it seems fairly certain that increases shown in Figs. 1*a*, *b* and *c* came from the same active regions. It is uncertain whether the pairs of increases in Figs. 1*d* and *e* are associated in the same way, but the time separations between the peaks are very close to 12 and 24 min respectively. There is also a small increase 6 min after the first main peak in Fig. 1*e*.

An examination has been carried out of the time profiles of a number of flares which have more than one peak in intensity. Fig. 2 is a histogram showing the time period between peaks. (Because these maxima are often broad, timing has generally been carried out from the points where the rate of flux increase becomes relatively insignificant. In a preliminary study the timing was taken between the points at which the flare increases commenced, but there appeared to be no marked periodicity.) There is strong evidence that the time separations between related peaks are multiples of about 6 min.

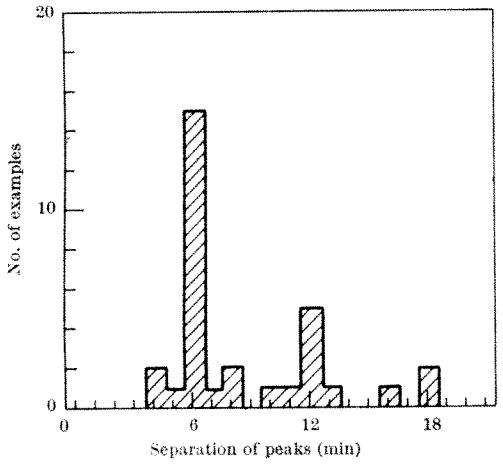

Fig. 2. Histogram of time separation between peaks of X-ray intensity. The data were collected over an observing period of about two weeks.

A possible explanation of the periodicity is that an oscillation of the X-ray emitting plasma volume occurs. There are, however, two reasons why this explanation does not seem satisfactory. (1) There seem to be examples of flare peaks 12 min apart with no intermediate large X-ray increases. If an oscillation of the flare volume occurred, each cycle would be expected to be observed until damping became significant. (2) An examination of Hα spectroheliograms has shown brightness changes at the times of precursor and main X-ray events which are up to one arc minute apart. If these separate Hα regions are indeed the ones corresponding to the individual X-ray peaks, then there is no single volume associated with the periodicity.

Because the 6 min time period is not greatly different from the 300 s oscillation observed at lower levels, it is worth speculating that the longer period arises as a result of the differences of height and magnetic field. In that case the flare increases would seem to be triggered by the arrival of energy in the solar atmosphere from the photosphere. I have already suggested (manuscript in preparation) that it is necessary to consider the plasma to be low in the chromosphere before the flare erupts. The material is then heated as it rises through the chromosphere in the vicinity of a magnetic instability or other heating mechanism. If this is the case it seems possible that the way in which the quiet corona is heated differs from the manner in which hot material is produced in flares only in the intensity of the event. Thus during times when no flare is observed, material rising from the photosphere is heated by hydromagnetic interaction with the magnetic field. If the magnetic field configuration is suitable, a magnetic instability might be produced and the material will be heated more effectively as a result. Unless this magnetic field configuration changes drastically during a flare it should be suitable to produce further heating of material rising about 6 min later. If, on the other hand, a change of field takes place so that no such heating can occur 6 min after the initial instability, it might still be possible for the field to have reverted to a suitable flare configuration by some multiple of 6 min later and further flare heating might occur.

I thank Professor R. L. F. Boyd and members of his group at the Mullard Space Science Laboratory.

Gravitational Radiation and the Oblique Rotator Model

It has been known for some time that gravitational radiation can play an important part in the energetic consideration of neutron stars[1,2] and its effects have been included in some of the recent investigations of pulsar models[3–5]. In all of this, however, only the energy loss has been considered, and the angular momentum loss has been completely ignored. We have recently looked into the problem for the case of an oblique rotator, and we obtained expressions for both of these losses. We have also listed out clearly the conditions when all these become comparable with effects from the magnetic dipole mechanism, and a comparison with conclusions reported by others[3,5] is also made.

Following Melosh[5] and Pacini[6], we take the oblique rotator model to be one in which pulsars are rotating neutron stars with a frozen in magnetic field, the axis of which is inclined at an angle with the rotation axis. We assume furthermore that the mass distribution is not spherically symmetric and we describe the distortion by a flattening of the star in the region of the magnetic poles. The flattening is thus also asymmetric with respect to the axis of rotation, and we therefore have a time dependent mass quadrupole moment which leads to gravitational radiation.

The energy loss in the weak field approximation to general relativity is given by[7]:

$$P_G = \frac{dE}{dt} = \frac{-G}{45c^5}\left(\frac{\partial^3 D_{ij}}{\partial t^3}\right)^2 = \frac{-G}{45c^5}(\dddot{D}_{ij})^2 \qquad (1)$$

say, where D_{ij} is the quadrupole moment tensor.

Angular momentum can also be lost through gravitational radiation at a rate given by[8]:

$$N_i = \frac{dL_i}{dt} = \frac{-2G}{45c^5}\,\varepsilon_{ijk}\,\dddot{D}_{jm}\,\dddot{D}_{km} \qquad (2)$$

where L_i is the ith component of the angular momentum vector **L** and ε_{ijk} is a completely antisymmetric unit pseudotensor (repeated indices are summed).

We take the pulsar to be a spheroid of mass M and semiaxes (a_1, a_2, a_3) with $a_1 = a_2$ and the axis of mass symmetry **m** (taken to be the same as the magnetic axis in our model) making an angle θ with the direction of

angular velocity $\boldsymbol{\Omega}$. In a reference coordinate system with the z axis along $\boldsymbol{\Omega}$ and the x–z plane containing $\mathbf{m}$, D_{ij} can be easily calculated and we then obtain the following for the energy and angular momentum loss:

$$P_G = \frac{-2G}{5c^5} I^2 \Omega^6 \varepsilon^2 \sin^2\theta (1+15\sin^2\theta) \quad (3)$$

$$N_x = \frac{12G}{5c^5} I^2 \Omega^5 \varepsilon^2 \sin^3\theta \cos\theta \quad (4a)$$

$$N_y = 0 \quad (4b)$$

$$N_z = \frac{-2G}{5c^5} I^2 \Omega^5 \varepsilon^2 \sin^2\theta (1+15\sin^2\theta) \quad (4c)$$

Chau[2] and Chin[9] have considered special cases of the problem.

In the above equations, ε is the ellipticity defined to be

$$\varepsilon = \tfrac{1}{2} e^2 \quad (5)$$

where the eccentricity e^2 is given by:

$$e^2 = 1 - \frac{a_3^2}{a_1^2} \quad (6)$$

and I is the moment of inertia:

$$I = \frac{2}{5} Ma^2 \quad (7)$$

with $a = (a_1 a_2 a_3)^{1/3}$.

The corresponding effects arising from the magnetic dipole mechanism are now familiar and one can readily obtain from Pacini[6] the energy loss expressions P_{EM} and from Michel[10] the radiation torques. Thus, for example:

$$P_{EM} = \frac{-2\pi}{3c^3} \Omega^4 H_s^2 a^6 \sin^2\theta \quad (8)$$

The ratio of P_G to P_{EM} can then be written as:

$$\frac{P_G}{P_{EM}} = \frac{3GI^2\Omega^2\varepsilon^2(1+15\sin^2\theta)}{5\pi c^2 H_s^2 a^6} \quad (9)$$

where H_s is the surface value of the magnetic field. For an order of magnitude estimate, we can take $\theta = \pi/2$ and the following data for a typical neutron star[3]:

$$M = 1{\cdot}4\ M_\odot = 2{\cdot}8\times10^{33}\ \text{g}$$
$$a = 1{\cdot}2\times10^6\ \text{cm}$$

With this, equation 9 becomes:

$$\frac{P_G}{P_{EM}} \sim 1{\cdot}5\times10^{26}\frac{\Omega^2\varepsilon^2}{H_s^2} \quad (10)$$

We see that with sufficiently high rotation frequency ($\Omega\sim10^4$ Hz) and an $H_s\sim10^{12}$ G, P_G would become comparable with P_{EM} for an ε as small as $\sim10^{-5}$.

If we now assume that the ellipticity is caused only by the presence of the magnetic field, then from Ferraro[11]:

$$e^2 = 2\varepsilon = \frac{H_i^2 a^8}{GI^2} \sim 3\times10^{-35} H_i^2 \quad (11)$$

where H_i is the interior field responsible for the distortion. Equation 11 can now be written as:

$$\frac{P_G}{P_{EM}} \sim 3\times10^{-44}\,\Omega^2\left(\frac{H_i}{H_s}\right)^2 H_i^2 \quad (12)$$

With the help of equations 10–12, we can therefore see clearly the effects of rotation and field strength on the relative importance of the gravitational and magnetic mechanisms. The conclusions reached are consistent with those of Ostriker and Gunn[3], but they differ substantially from Melosh's[5], where the result is

$$\left(\frac{P_G}{P_{EM}}\right) \sim 3\left(\frac{\Omega a}{c}\right)^2$$

The difference arises, we believe, from the fact that the energy loss expression in the latter's work contains an e^2 whereas it should be $\varepsilon^2(=\frac{1}{4}e^4)$ as shown in equation 4. Our main result then is that the angular momentum loss and the torques arising would become comparable with those from magnetic dipole radiation under conditions discussed above. They should therefore be taken into consideration in the alignment calculations recently reported[10,12,13]. This calculation will be reported in a separate communication.

I thank Professor R. N. Henriksen for help. This research is partially supported by a Canadian National Research Council grant.

Convection Currents and the Constant Q-Mechanism

Jeffreys has raised an interesting objection[1] to the possibility of convection or steady-state creep occurring in the upper mantle. Lomnitz has shown[2] that the logarithmic stress–strain relationship observed in igneous rocks in the laboratory may be used to derive an attenuation coefficient for stress waves that is directly proportional to frequency (constant-Q) over a limited range of frequency. Jeffreys argues that as the logarithmic creep behaviour is associated with the constant Q behaviour of stress waves, and experimental data indicate that stress waves in the mantle exhibit constant Q, the mantle material cannot undergo steady state creep under a constant stress.

Press[3] and Anderson and Kovach[4] have established that Q is constant, over the period range 11 to 25 s, as an average for the mantle as a whole. Calculations of the detailed variation of Q with depth from surface wave studies[5] assume, however, that Q is constant with frequency. If this assumption is accepted, does it necessarily preclude steady state creep ?

The logarithmic stress–strain relationship for igneous rocks is

$$\varepsilon = \frac{P}{\mu}[1 + q\log(1 + at)] \quad (1)$$

where ε is the strain, P the stress, μ the rigidity, q and a are experimentally determined constants, a being of the order of 10^3 s^{-1}. The wave equation based on (1) (ref. 2) gives a constant value of Q in the frequency range $10^{-8} < f < 1$Hz, provided that Q (which is proportional to q^{-1}) is greater than 600.

It has been established experimentally[6] that the values of Q for most rocks are constant over the frequency range $10^{-4} < f < 10^6$ Hz, the absolute values being about 200. Thus Q is constant over a range of frequencies which is not explicable in terms of the logarithmic stress–strain relationship and it must therefore be presumed that there are other mechanisms that can give rise to this behaviour.

Futterman has shown[7] that the constant Q behaviour cannot extend to zero frequency if the causative mechanism is linear. Experimental evidence for this linearity has been provided for metals by Savage and Hasegawa[8] and for sediments by myself[9] and shows that the superposition theorem is valid for stress waves showing constant Q propagation in these materials. Hence the constant Q mechanism cannot manifest itself at zero frequency as a particular stress–strain relationship and its presence cannot be taken as evidence for or against such a relationship.

An analogous situation arises in the study of the damping of electromagnetic waves in dielectrics. The values of Q of many dielectrics are independent of frequency[10] and cannot be derived from the d.c. conductivities. But the presence of the constant Q mechanism cannot be taken as evidence that a steady state, unidirectional flow of charge cannot occur through dielectrics, because it is known experimentally that they have measurable d.c. conductivities.

If the material of the mantle can undergo steady state creep it would be expected that a "viscous" attenuation mechanism with a characteristic relaxation time would be observed. McConnell has estimated[11] the viscosity of the upper mantle as 10^{20} to 10^{22} poise from the rate of uplift of Fennoscandia. The implied relaxation time is between 5×10^7 and 5×10^9 s. Bhatia shows[12] that stress waves with periods considerably less than the relaxation time are not attenuated or dispersed by the viscous mechanism. Thus there will be no evidence for this damping mechanism from stress waves of "ordinary" seismic periods. Jeffreys indicates[1] that the free nutation of the Earth's axis (an oscillation with a period of about 4×10^7 s) shows a viscous damping with a time constant of about 10^8 s. The agreement between the two relaxation times lends support to the idea that the upper mantle material can exhibit steady state creep.

Plate-tectonic Regulation of Faunal Diversity and Sea Level: a Model

A growing body of evidence and theory supports the idea that processes of plate tectonics have been operating for the past 3×10^9 years[1]. The hypothesis of ocean-driven plates implies that certain mountain systems represent the remains of former large ocean basins. An important corollary of this notion is that the history of continental assembly and fragmentation can be inferred from the geological record of the various mountain systems. We show here how the diversity of marine fauna and fluctuations in sea level can be related to patterns of continental fragmentation and reassembly. It seems that changes in the diversity of fauna predicted from these patterns can account for a great deal of the variation in the diversification and extinction of marine biota that has long puzzled palaeontologists. The timing of major transgressions and regressions predicted from these patterns also agrees well with the observed record.

Among the factors that regulate species diversity are environmental stability[2,3], food supply[2,4,5] and provinciality[6,7]. Consider a large land mass composed of an assembly of all the presently dispersed continents. Such a continental state favours great seasonality of marine climate, partly as a result of excess summer heating and winter cooling of the interior compared with the surrounding oceans. Off-shore winter and spring winds cause upwelling which results in relatively low surface temperatures and high supplies of nutrients in coastal waters; on-shore summer and autumn winds favour the on-shore drift of relatively warm surface waters and low levels of nutrients in coastal waters. Barriers to migration are few, and although some endemism would occur in epicontinental oceanic arms and along topographically distinctive coastal stretches, species would tend to be widespread, especially if climatic differences around the continental margin were not too extreme.

If such a supercontinent were to fragment, the marine climates around the small daughter continents would have a different character. In general, the climates of these smaller land masses would be more equable, with less distinct seasonality arising from monsoon effects and with less vertical mixing and therefore fewer nutrients in shelf waters. In this more stable, more "oligotrophic" environment, increasing species diversity within communities is favoured[2,5,8]. Furthermore, there is now growing isolation of the biotas of the daughter continents, leading to growing endemism and the eventual appearance of distinctive biotas on each continent, increasing the total biotic diversity. Total species diversity has thus increased as a result of the increased stabilization of the shelf environment and the accompanying oligotrophic tendency, and the increased provincialization.

Subsequent reassembly of smaller continents into larger ones leads to an increase in seasonality in shelf waters and to increased supplies of nutrients, and also eventually brings endemic biotas into association. A significant reduction in diversity would thus occur. Extinction would be greatest among groups that were least pre-adapted to fluctuating conditions (usually the deeper shelf forms[9,10] and very specialized forms in general), and among groups that were unable to meet the competition or to withstand the predation pressures from invading members of the other biotas. Diversity would tend to be lowest when all continental fragments were reassembled into a single supercontinent, and highest when continents are most fragmented. Climatic zonation is, however, another major cause of provincialization; if continental configurations are such that latitudinal temperature gradients are high, then the biota of each north–south continental coast will be subdivided into climatic provinces and diversity levels will be multiplied by this factor. This situation partly accounts for the unusually high number of species at present[11,12].

A model of continental breakup and reassembly can be inferred from existing mountain chains[1]. Phanerozoic events were probably directly affected by the breakup of an early supercontinent (Pangaea I, Fig. 1, event *A*) which by the time of the upper Cambrian had given rise to a pre-Appalachian and pre-Hercynian and pre-Uralian ocean[13–17] (Fig. 1, event *B*). Judging from the emplacement of ophiolites[18,19], the pre-Caledonide–Acadian ocean began closing by the mid-Ordovician and was sutured in the late Silurian to late Devonian (Fig. 1, event *C*). The pre-Hercynian and pre-Appalachian oceans closed in the late Pennsylvanian or early Permian (Fig. 1, event *D*). Finally, the closing of the pre-Uralian ocean near the end of Permian time completed the reconstruction of a supercontinent (Pangaea II, Fig. 1, event *E*).

seem to correlate well with the events described. The correspondence seems close enough to support one of our principal theses, that a major part of the regulation of species diversity on continental shelves has been accomplished through changes in environmental stability, nutrient supply and provinciality which act in concert and are correlated with changes in continental configurations. The continuing rediversification during the Mesozoic and Cainozoic is partly the result of the widening latitudinal spread of continents and of the development of latitudinal chains of provinces as shelf waters have cooled in high latitudes[9,10].

The patterns of continental assembly and fragmentation inferred earlier also suggest a model which may explain a long standing enigma: the timing and correla-

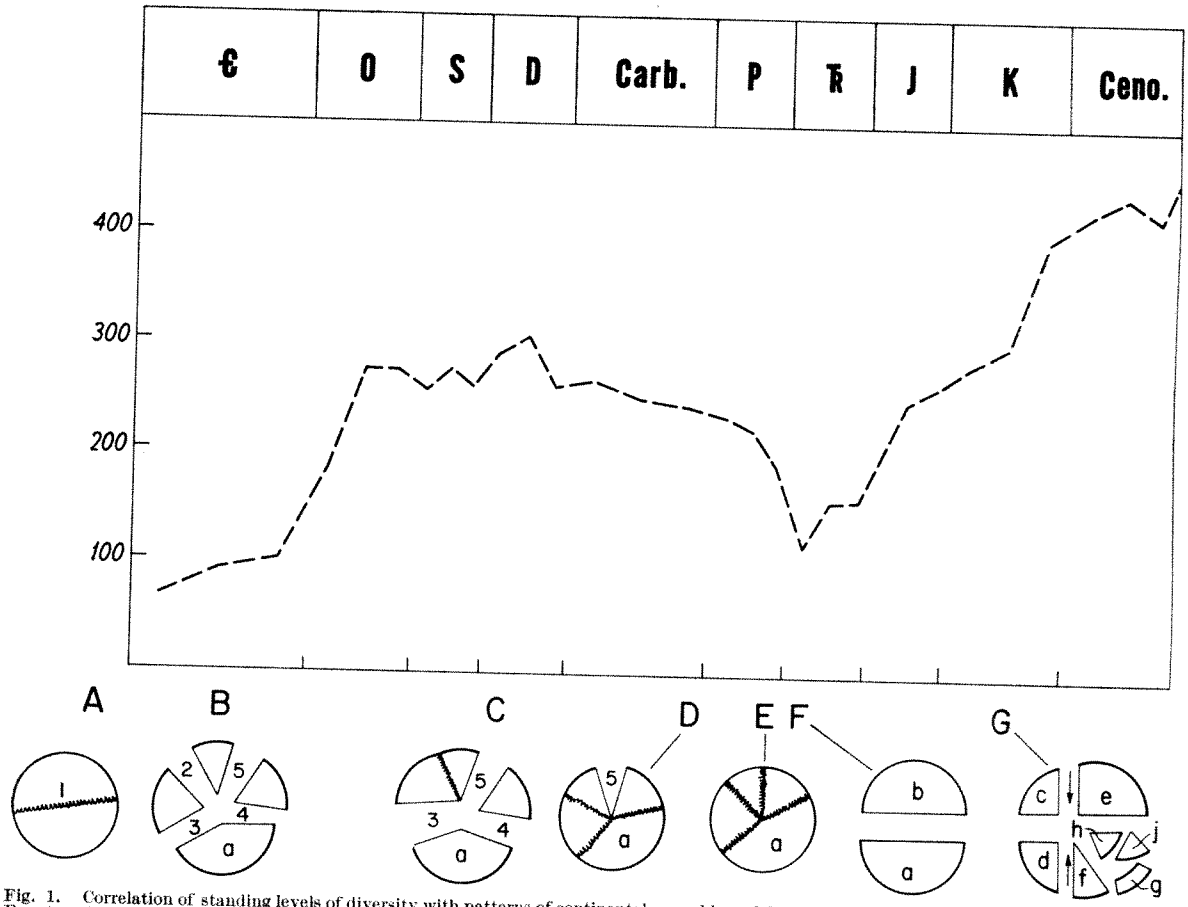

Fig. 1. Correlation of standing levels of diversity with patterns of continental assembly and fragmentation. Broken line is number of families. Events: *A*, Eocambrian suturing of Pan-African-Baikalian (1) system—formation of Pangaea 1; *B*, fragmentation of *A* in Cambro-Ordovician time to give pre-Caledonian–Acadian (2), pre-Appalachian (3), pre-Hercynian (4), and pre-Uralian (5) oceans; *C*, Siluro-Devonian suturing of Caledonian–Acadian orogenic system; *D*, Pennsylvanian–Permian suturing of Appalachian–Hercynian orogenic system; *E*, Permian–Triassic suturing of Urals—formation of Pangaea II; *F*, Triassic–lower Jurassic extension of Tethyan seaway; *G*, Cretaceous–Recent closing of Tethys, opening of Atlantic, fragmentation of Gondwana. *a*, Gondwana; *b*, Laurasia; *c*, North America; *d*, South America; *e*, Eurasia; *f*, Africa; *g*, Antarctica; *h*, India; *j*, Australia.

This Permo-Triassic supercontinent was short-lived, however, and separated into Laurasia and Gondwana as a result of the extension of the Tethyan ocean (Fig. 1, event *F*). Subsequent breakup of both these continental masses has been accompanied by a partial closure of Tethys, probably commencing in the late Jurassic to early Cretaceous (judging by the emplacement of ophiolites[20–23]) and may have been accelerated by the opening of the North Atlantic and fragmentation of Gondwana in mid-Cretaceous times (Fig. 1, event *G*).

The diversity of skeletonized benthonic shelf families of nine major invertebrate phyla is shown in Fig. 1[11,12]. The number of families present (family diversity) is represented by epoch; the major trends in standing diversity tion of major transgressions and regressions on presently separated continents.

Our model involves an expansion and application of a principle suggested by Russell[24]. Continental fragmentation occurs at ridges where ocean floor spreading is in progress. These ridges stand above the general abyssal plains to form broad topographic highs which, even on the scale of the world ocean, contain significant volume. A rough calculation based on published data[25–28] indicates that the volume of present ridges is about $2{\cdot}5 \times 10^8$ km^3, which would be sufficient to lower the ocean level by about 0·5 km across the entire surface of the Earth, or by about 0·65 km over the present ocean basins, were they to subside.

The lateral displacement of continents involves at least partial destruction in subduction zones[23] of either the plate on which they are borne or of another plate; these zones are expressed as topographic lows. As the continents move apart they displace ocean water from deeper regions bordering their outer edges, while the sea floor appearing between them, partly composed as it is of a ridge, stands relatively high. The total volume of the ocean basins is therefore reduced and water tends to rise relative to the continental platforms, which undergo transgressions.

If, on the other hand, continents are being joined, their suturing prevents further relative motion between the plates on which they ride. In this event, the component sea floor spreading of the world rift system which accounted for the relative motion between the now-sutured plates must eventually decay or new subduction zones must develop. There is evidence that if the spreading stops, the ridges subside[30–33], perhaps resulting from cooling and downward growth of the lithosphere. If new subduction zones develop, they would be associated with trenches. In either case, there would be an increase in volume of the ocean basins, and therefore an epicontinental regression.

According to this model, assembly of continents should be accompanied by regressions, and fragmentation by transgressions. In so far as the record is amenable to interpretation in these terms, these relations seem to hold. The emergent Eocambrian supercontinent (or continents; Fig. 1, event *A*) fragmented and was then transgressed during Cambrian time (Fig. 1, event *B*). Caledonian–Acadian, Hercynian and Appalachian suturings (Fig. 1, events *C*, *D*) were accompanied by regressions. Permo-Triassic continental assembly (Fig. 1, event *E*) was accompanied by a profound regression. Subsequent transgressions may mark episodes of fragmentation (Fig. 1, events *F*, *G*), as is suggested by the correlation of major continental breakup near the mid-Cretaceous with a widespread transgression. Post-Cretaceous sea level changes may have involved such events as movements on the "Darwin Rise"[27], suturing and continental underthrusting in the Alpine–Himalayan belt, and the well known eustatic effect of ice and snow storage.

The expected effects of transgressions and regressions tend to reinforce the effects of the ecological regulators of diversity. Widespread transgressions would tend to moderate the seasonal climates, while widespread regressions would tend to enhance continentality. Furthermore, the species-area effects of expanding and shrinking of the epicontinental seas, which may have less influence on marine biotic diversity than these other factors[5], would nevertheless be of some significance. According to the present hypothesis, all these factors operate in concert.

Molecular and Crystal Structure of Nonachloroclovononaborane, B_9Cl_9

In a recent publication[1] we described the isolation and characterization of a yellow–orange boron subchloride, B_9Cl_9. The structure of this compound has now been determined from three-dimensional X-ray data collected by counter methods.

Attempts to grow single crystals by sublimation were unsuccessful, but well formed orange rhombs were obtained by crystallization from methylene chloride in high vacuum conditions. The compound crystallizes with four molecular units in the space group A2/m of the monoclinic system. Crystal data: $a = 9{\cdot}25$ Å, $b = 12{\cdot}66$ Å, $c = 13{\cdot}50$ Å; $\beta = 95{\cdot}1°$. Volume of unit cell = 1549 Å^3. Measured density (flotation in mixtures of organic solvents) was 1·7 g/cm^3, calculated density 1·78 g/cm^3.

Diffraction data to $2\theta = 50°$ (Mo-K_α radiation) were collected on a manual General Electric XRD-6 diffractometer. The structure was solved by Patterson, Fourier and least-squares refinement techniques. The coordinates and anisotropic thermal parameters of all atoms were refined to the present discrepancy factor of $R = 6{\cdot}5$ per cent using 1,305 independent reflexions above background. The relevant details of the parameters of the molecule are summarized in Table 1.

Table 1. Interatomic distances in (Å)

Atoms		Distances	Standard deviation
B_1	B_4	1·729	0·009
B_1	B_5	1·733	0·010
B_2	B_5	1·806	0·009
B_2	B_6	1·751	0·009
B_3	B_4	1·812	0·009
B_3	B_6	0·739	0·009
B_4	B_6	1·735	0·009
B_5	B_6	1·766	0·009
B_1	Cl_1	1·729	0·008
B_2	Cl_2	1·748	0·008
B_3	Cl_3	1·738	0·008
B_4	Cl_4	1·741	0·006
B_5	Cl_5	1·746	0·006
B_6	Cl_6	1·721	0·007

As shown in Fig. 1, B_9Cl_9 has a boron-cage structure with terminal chlorine atoms on each boron. The cage has the shape of a tri-capped trigonal prism with three boron atoms and their associated chlorines sitting on the crystallographic mirror plane; within experimental error the molecule has a three-fold axis although this is not a space group requirement. The B–B and B–Cl bond lengths are in close agreement with those found by Lipscomb for the related compound[2,3], B_8Cl_8. Both B_8Cl_8 (G. F.

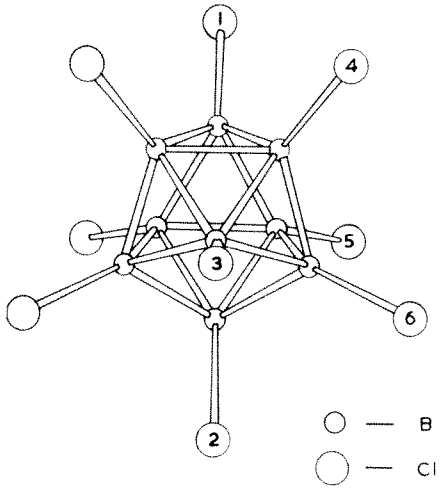

Fig. 1.

Lanthier, J. K., and A. G. M., to be published) and B_9Cl_9[1] are formed during the thermal decomposition of diboron tetrachloride.

Plastic Deformation and Anisotropy in the Hardness of Diamond

A number of methods may be used to determine the hardness of solids. The most reproducible and most widely used for crystalline solids are those in which the size of an indentation is measured after the surface of the specimen has been subjected to deformation by an indenter under a known normal load. Ideally, the indenter material should be considerably harder than the specimen in order to avoid inaccuracies due to deformation of the indenter tip, but this implies that the hardness of diamond cannot be measured, for it is the hardest indenter material available. A limited amount of data concerning the hardness of diamond, using the static indentation technique, has nevertheless been published. More than thirty years ago the Knoop indenter was developed and used to measure the hardness of a wide range of ductile and brittle materials. This indenter produces an indentation in the form of a parallelogram with one diagonal at least seven times longer than the shorter diagonal. In that early work, the hardness of diamond was quoted as 8,000–8,500 kg mm^{-2} (ref. 1). No details were given concerning the normal load used, the type of deformation associated with the indentation or the crystallographic relationships between the indenter and the indented diamond surface. It was reported subsequently that the hardness of a (001) diamond surface, again using the Knoop indenter and a normal load of 500 g, was 6,000–6,500 kg mm^{-2}. Apparently, anisotropy in the hardness could not be detected at that time[2]. Bernhardt[3] gave a limiting value of 10,000 kg mm^{-2} on the (111) surface. He used a conventional square based pyramidal indenter and a normal load of 200 g. Kruschov and Berkovich[4], using an indenter in the form of a three sided pyramid with an angle of 65° between its geometrical axis and the side faces, derived a hardness of 10,060 kg mm^{-2} from one indentation also on a (111) plane and with a load of 200 g. On the basis of a very limited number of indentations, therefore, it seems that the hardness of diamond lies between 6,000 and 10,400 kg mm^{-2} with no evidence of anisotropy. On the other hand, studies of abrasion on diamond surfaces have established marked anisotropy in wear resistance. These observations have been used to suggest that the directions of high and low wear resistance represent the hard and soft directions respectively on a given diamond surface. For example, it has been proposed[5] that, on the (001) plane of diamond, the hard directions are ⟨110⟩ and the soft directions are ⟨100⟩. It is now clear that directions of high wear resistance, on a given crystal plane, are not necessarily the hard directions[6].

Table 1. KNOOP HARDNESS MEASUREMENTS ON A (001) DIAMOND SURFACE

Chronological order of indentation	Direction	Hardness (kg mm^{-2})	Deformation
1	[010]	9,400	No cracking
4	[100]	9,400	No cracking
6	[010]	9,600	No cracking
10	[100]	10,400	No cracking
12	[010]	9,400	No cracking
14	[100]	9,400	No cracking
16	[010]	8,900	No cracking
2	[110]	7,700	No cracking
3	[1$\bar{1}$0]	6,600	No cracking
5	[110]	7,000	No cracking
7	[110]	5,700	Cracking
8	[110]	7,600	Slight cracking
9	[110]	6,400	Slight cracking
11	[1$\bar{1}$0]	7,700	No cracking
13	[110]	—	Extensive cracking
15	[1$\bar{1}$0]	7,000	No cracking
17	[110]	6,000	No cracking

Anisotropy in the hardness of crystals can be most effectively studied by Knoop indentation measurements where the indenter is aligned so that the long diagonal in the indentation corresponds to a specific crystallographic direction on a crystal plane. The length of the longer diagonal is then used to calculate the hardness. The purpose of the present work was to use the Knoop indenter to investigate anisotropy in the hardness of diamond. The indentations were made on the same (001) diamond surface as that used in earlier work on the frictional anisotropy of diamond by Bowden *et al.*[7] and Bowden and Brookes[8]. Measurements were carried out on this (100) surface in ⟨100⟩ and ⟨110⟩ directions using normal loads of 500 g, 1 kg and 2 kg. There is a good deal of elastic recovery in diamond and the indentations at 500 g were difficult to measure with sufficient accuracy to establish anisotropy effects. Also a significant amount of fracture was observed around the indentation at 2 kg in the ⟨110⟩ directions although this was never observed in the ⟨100⟩ directions at any load. Most of the measurements were therefore made with a normal load of 1 kg. Hardness values are given in Table 1 for all these measurements and typical indentations produced by a 1 kg load for the two principal directions on the (001) plane are shown in Fig. 1. A further single indentation in the [120] direction gave a hardness value of 8,900 kg mm^{-2}.

For such a hard material, there is surprisingly little scatter in the hardness for the ⟨100⟩ directions, and the average value is 9,600 kg mm^{-2}. The scatter is greater for the indentations in ⟨110⟩ directions, but the average value is approximately 6,900 kg mm^{-2} whether based on all the measurements or just on those where cracking was not observed. Clearly the hard directions on a cube diamond surface are ⟨100⟩ and the soft directions are ⟨110⟩. This is in direct contradiction to the earlier conclusions based on abrasion resistance and confirms the suggestion that different mechanisms control the two processes[6].

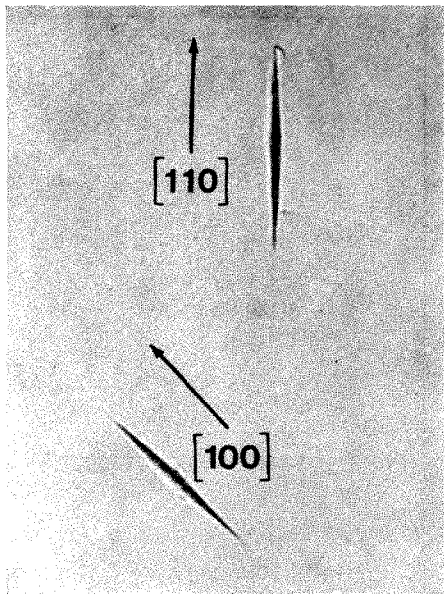

Fig. 1. Knoop indentations in the [$\bar{1}$10] and [$\bar{1}$00] directions on the (001) plane of diamond. (×750.)

The observations made in this study also serve to resolve the controversy concerning the possibility of plastic flow in diamond at room temperature. Recently, Gane and Cox[9] used a scanning electron microscope to observe the mutual indentation of crossed diamond knife edges. They concluded that plastic deformation in diamond was not possible at room temperature except perhaps in very small amounts not resolvable in the scanning electron microscope. There can be very little doubt, however, that the indentations obtained in this work, such as those shown in Fig. 1, were formed by plastic flow. Furthermore, the observed anisotropy was predictable on the basis of a study by C. A. B., J. B. O'Neill and B. R. W. Redfern on anisotropy in the hardness of crystals using the Knoop indenter (to be published). They have established a clear relationship between the effective resolved shear stresses developed in the bulk of the crystal beneath the indenter and the primary slip system in a given crystal structure. Their analysis was shown to be equally applicable to a wide range of metallic and nonmetallic crystals, covering hardness values from 13 to 3,000 kg mm^{-2}, but is valid only when dislocations are mobile in the given experimental conditions. When this analysis is applied to the diamond cubic structure, assuming slip is possible on {111} ⟨1$\bar{1}$0⟩ systems[10], the effective resolved shear stress calculations confirm that the hard and soft directions should be ⟨100⟩ and ⟨110⟩ respectively on low index planes. It has also been shown that cracking is most likely in the softer directions on such crystals as magnesium oxide and aluminium oxide and does not significantly influence the hardness measurements (C. A. B., O'Neill and Redfern). The results obtained in this study are therefore entirely consistent with those in the earlier work with the Knoop indenter and confirm that plastic flow is possible in diamond at room temperature.

I thank Professor H. G. Edmunds and Dr H. Zienkiewicz for discussion, Miss Jill Kent for technical assistance and the SRC and UKAEA for grants.

BIOLOGICAL SCIENCES

Tissue-specific Factor required for the Translation of a Mammalian Viral RNA

RNA from several mammalian viruses promotes protein synthesis in cell-free systems from certain mammalian and avian cells[1–5]. We have recently investigated a cell-free preparation derived from mouse Krebs II ascites cells which responds to RNA from encephalomyocarditis virus (EMC) (M. B. M. and A. Korner, unpublished). The EMC RNA-directed product is virus-specific, which confirms that the viral RNA is acting as a messenger RNA. We have found that cell-free systems prepared from certain other mammalian cells fail to respond with amino-acid incorporation, and that the unfractionated rabbit reticulocyte system evinces an inhibitory response. This inhibition is caused by an interference with the normal process of globin chain initiation (M. B. M. and A. Korner, manuscript in preparation), comparable with that produced by the synthetic polynucleotides poly U and poly A in this system[7,8]. No detectable amino-acid incorporation, however, is directed by the viral RNA. We show here that reticulocyte ribosomes can translate EMC RNA but that reticulocytes lack at least two soluble components necessary for the response.

Viral RNA and protein-synthesizing extracts were prepared from rabbit reticulocytes and mouse Krebs II ascites cells by the methods previously described (unpublished results of M. B. M. and A. Korner). Where applicable, the unfractionated systems were preincubated for 40 min at 37° C with the cofactors of protein synthesis to reduce the endogenous incorporation. Ribosomes and cell sap were separated by centrifugation for 2·5 h at 165,000*g* (average). Ribosomes were spun through 1 M sucrose in incubation medium. Incubations were carried out in a medium containing 5 mM magnesium acetate, 125 mM KCl, 30 mM Tris-HCl (*p*H 7·5) and 6 mM 2-mercaptoethanol.

To clarify the difference between the reticulocyte and ascites cell systems in their response to EMC RNA, ribosomes and cell sap were exchanged between the systems. A preliminary experiment (Table 1) indicated that the endogenous incorporation of non-preincubated ribosomes could be maintained by heterologous sap. This

Table 1. ENDOGENOUS AND POLY U-PRIMED SYNTHESIS IN MIXED SYSTEMS

Ribosomes	Sap	^{14}C-Phenylalanine incorporation (c.p.m.) Control	+Poly U	Relative stimulation
Reticulocyte	Reticulocyte	5,160	35,584	7·0
Reticulocyte	Ascites	5,076	10,516	2·1
Ascites	Reticulocyte	2,109	27,176	13·3
Ascites	Ascites	1,921	4,389	2·3

Reactions (0·3 ml.) contained 0·15 ml. sap, 100 μg reticulocyte or 140 μg ascites ribosomes (non-preincubated), 1 mM ATP, 0·1 mM creatine phosphate, creatine phosphokinase 0·2 mg/ml., naturally occurring amino-acids except phenylalanine 20 μM each, 0·5 μCi/ml. ^{14}C-phenylalanine (450 mCi/mmole), 100 μg poly U where indicated, and salts as in the text. After 45 min at 37° C, 0·5 ml. 1 M NaOH containing 2 per cent casamino acids was added and incubation was continued for 15 min. Protein was precipitated with 2 ml. 20 per cent trichloroacetic acid, collected on glass-fibre filters and washed. Radioactivity was estimated with a Nuclear-Chicago gas-flow counter at an efficiency of 25 per cent.

Table 2. RESPONSE OF MIXED SYSTEMS TO EMC RNA

Ribosomes	^{14}C-Phenylalanine incorporation (c.p.m.) Ascites sap		Reticulocyte sap	
	Control	+EMC RNA	Control	+EMC RNA
Ascites	86	1,475	96	14
Reticulocyte	200	1,619	188	203

Reactions (0·1 ml.) contained 0·03 ml. sap, 25 μg preincubated ribosomes and, where indicated, 2 μg EMC RNA. Other conditions were similar to those of Table 1. Identical observations have been made with non-preincubated ribosomes. The absence of an inhibitory response in the homologous reticulocyte system is probably due to the decreased extent of globin chain initiation after fractionation of the S-10 into ribosomes and sap[6].

shows that the supernatant factors—sRNA and transfer enzymes—are compatible. The heterologous systems also responded to poly U, though ascites cell sap permits less stimulation—possibly because it contains ribonuclease (unpublished results of M. B. M. and A. Korner). Stimulation by EMC RNA unequivocally requires ascites cell sap, reticulocyte sap being totally ineffective (Table 2), even when its concentration is increased (data not shown). The viral RNA can stimulate protein synthesis from ribosomes of either source in the presence of ascites cell sap. To characterize the products of the cell-free incorporations, incubations were carried out in the presence of ascites cell sap and ^{35}S-methionine and the proteins were digested with trypsin and subjected to electrophoresis. The peptide patterns obtained from preincubated reticulocyte and ascites cell ribosomes

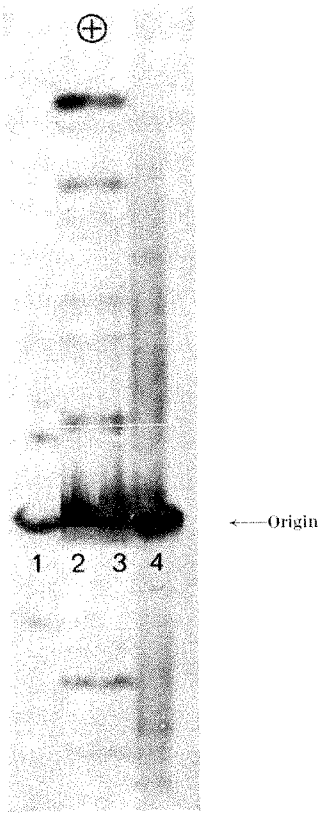

Fig. 1. Tryptic digestion of ^{35}S-methionine labelled cell-free products. (1) Reticulocyte ribosomes, endogenous; (2) reticulocyte ribosomes, EMC RNA-directed; (3) ascites ribosomes, EMC RNA-directed; (4) ascites ribosomes, endogenous. Incubations (50 μl.) contained 30 μl. ascites sap, 25 μg ribosomes, 1 μCi ^{35}S-methionine (20 Ci/mmole), nineteen labelled amino-acids, except methionine, 20 μM each, and other components as detailed in Table 1. Reactions 1 and 2 contained reticulocyte ribosomes and 3 and 4 ascites ribosomes; reactions 1 and 4 used non-preincubated ribosomes, and 2 and 3 preincubated ribosomes + 3 μg EMC RNA. After 45 min, EDTA was added to 50 mM and incubation was continued for 5 min with 1 μg pancreatic ribonuclease. Proteins were precipitated with 5 per cent trichloroacetic acid containing 2 per cent casamino acids, washed three times with trichloroacetic acid and then with ethanol, ethanol: ether and ether. The dried precipitate was oxidized with performic acid, dissolved in 1 per cent ammonium bicarbonate and digested with trypsin for 4 h at 37°. After lyophilization, the digest was applied to Whatman '3MM' paper and electrophoresed at pH 6·5 for 75 min at 3 kV. The dried paper was autoradiographed for 10 days. Material remaining at the origin is attributable to underdigestion.

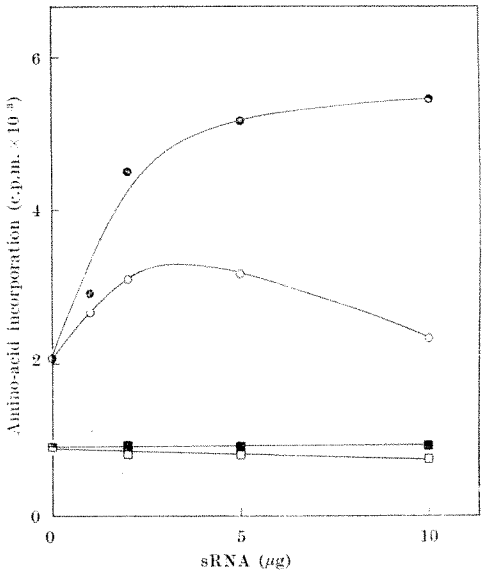

Fig. 2. Dependence of response to EMC RNA on added sRNA. Reactions (50 μl.) contained 10 μg preincubated ascites ribosomes, 25 μl. reticulocyte sap, 15 μl. DEAE-cellulose treated ascites sap and sRNA and EMC RNA (2 μg) where indicated; ●, ascites sRNA + EMC RNA; ○, reticulocyte sRNA + EMC RNA; ■, ascites sRNA, no EMC RNA; □, reticulocyte sRNA, no EMC RNA. The small stimulation obtained in the absence of added sRNA is attributable to slight contamination of the ascites ribosomes with sap, and is not seen if reticulocyte ribosomes are used. A similar partial replacement of the requirement for ascites sRNA by reticulocyte sRNA is observed in the reticulocyte S-10 supplemented with treated ascites sap.

under the influence of EMC RNA are identical (Fig. 1), and similar to those previously demonstrated to be virus specific[6]. Reticulocyte ribosomes therefore translate the viral RNA faithfully in the presence of ascites cell sap. The EMC RNA-directed peptides are quite distinct from those produced by non-preincubated ribosomes from either source.

The addition of reticulocyte sap to incubations containing ribosomes and ascites cell sap does not suppress the stimulation of protein synthesis by EMC RNA (Table 3). Furthermore, supplementation of the reticulocyte S-10 (the unfractionated 10,000g supernatant) with ascites sap dramatically transforms its inhibitory response to the viral RNA into a stimulation (Table 3). This shows that the reticulocyte sap does not contain components which inhibit the translation of EMC RNA, and implies that the ascites sap contains factors, absent from reticulocyte sap, which are necessary for the translation of the viral RNA. Fractions of ascites sap were therefore added to incubations containing preincubated ribosomes and reticulocyte sap in the presence and absence of EMC RNA. If ascites sap is warmed to 55° C for 2 min, it no longer permits the stimulation, suggesting that a protein is involved. Treating the ascites sap with DEAE-cellulose at 0·125 M KCl, which removes the sRNA and some of the proteins, virtually abolishes its activity (Table 4). Raising the KCl concentration to 0·3 M to prevent the adsorption by DEAE-cellulose of almost all the proteins does not restore the activity. If, however,

Table 3. EFFECT OF EXTRA SAP ON THE RESPONSE TO EMC RNA

Experiment	Ribosomes	Reticulocyte sap	Ascites sap	Incorporation (c.p.m.) Control	+EMC RNA
1	Ascites	30	0	96	14
	Ascites	0	30	86	1,475
	Ascites	30	30	50	1,770
	Ascites	60	30	79	1,464
2	Reticulocyte S-10		0	11,653	6,142
	Reticulocyte S-10		10	10,518	47,407

The conditions for experiment 1 were identical to those of Table 2. In experiment 2, reactions (25 μl.) contained 10 μl. reticulocyte S-10, 1 μCi ^{35}S-methionine (20 Ci/mmole), unlabelled amino-acids except methionine 20 μM each, and 5 μg EMC RNA where indicated. Other details are as under Table 1.

Table 4. EFFECT OF ASCITES SAP FRACTIONS ON THE RESPONSE TO EMC RNA

DEAE-cellulose treated ascites sap (μl.)	Ascites sRNA (μg)	Incorporation (c.p.m.) Control	+ EMC RNA
0	0	43	232
0	14	41	466
15	0	76	513
15	14	81	2,105
Unfractionated ascites sap (15 μl.)		114	2,773

Reactions (50 μl.) contained 25 μl. reticulocyte sap, 5 μg preincubated ascites ribosomes and ascites sap fractions and EMC RNA (2 μg) as indicated. Other details were similar to those of Table 1. Increasing the amounts of treated sap or sRNA did not increase the response observed. The ascites sRNA was prepared by phenol extraction of ascites cell sap, followed by alcohol precipitation and ether washing. It was discharged by incubation in 1·8 M Tris-HCl (*p*H 8·5) for 1 h. Ascites sap was treated with DEAE-cellulose by passing it through a column of Whatman 'DE 52' equilibrated with incubation medium. Treatment at 50 mM KCl resulted in complete loss of the stimulatory activity.

the treated sap is supplemented with ascites sRNA (obtained by phenol extraction of untreated sap) the activity returns: the sRNA alone is ineffective (Table 4). Likewise, both the protein and sRNA fractions are required to overcome the inhibitory action of EMC RNA in the reticulocyte S-10. Fig. 2 shows that reticulocyte sRNA can substitute for the ascites sRNA, but is less efficient.

The requirement for sRNA may signify that EMC RNA contains one or more codons which are rare in globin and for which the reticulocytes have little tRNA. They may also lack the cognate amino-acid activating enzyme, which would explain the need for a protein factor. In this case, charged ascites cell sRNA might be sufficient to permit stimulation by EMC RNA in the absence of the protein component, but experiments have not supported this hypothesis. Nor have any short EMC RNA induced peptides been found in the reticulocyte system, which indicates that the block in the translation of the viral RNA occurs at initiation rather than at an early step of chain elongation. The DEAE-cellulose treated sap, supplemented with ascites sRNA, can support the translation of poly U by ascites ribosomes, so it is unlikely that the protein factor is one of the transfer factors. These experiments are not conclusive and further fractionation of both the protein and RNA components is being undertaken.

The phenomenon described here may be general: mouse brain and mouse reticulocyte systems are also incapable of responding to EMC RNA because of sap inadequacy, although mouse liver systems can respond (unpublished results). These factors may perform a role similar to that of the messenger-specific initiation factors of bacteria[9–11], and are perhaps concerned in the regulation of protein synthesis *in vivo*.

I thank Dr A. T. H. Burness and Dr L. V. Crawford for help in growing the virus; Dr K. A. Marcker for his advice and suggestions; Professor A. Korner for his interest in the early part of this work; and several colleagues for reading the manuscript. I am a Beit Memorial Research fellow.

Absolute Stereochemistry of the Second Step of Ribonuclease Action

PANCREATIC ribonuclease catalyses the decomposition of a ribonucleic acid by a two-step mechanism: a transesterification followed by hydrolysis of the resulting cyclic phosphate[1]. The various mechanisms suggested can be classified as either "in-line" or "adjacent" depending on the relative geometry of the incoming and outgoing groups during the displacement reaction[2] (Fig. 1). In particular, any simple mechanism in which it is assumed that the same group acts first as a general base toward the attacking nucleophile, then as a general acid toward the leaving group, implies an adjacent geometry. The alternative, in which there is a considerable movement of either the catalytic group or the substrate, is unlikely. The two steps may, however, have different mechanisms according to this criterion without violating microscopic reversibility, for a nucleoside is obviously not necessarily equivalent to a water molecule[3].

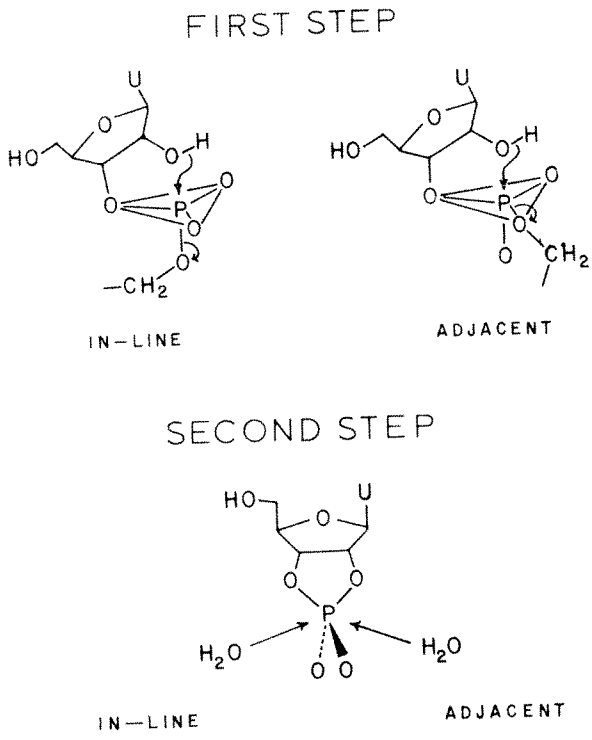

Fig. 1. The in-line and adjacent mechanisms for the two steps of ribonuclease action. In the adjacent mechanisms, the molecule would undergo a pseudorotation before product formation[2].

The earliest suggested mechanism was in-line[4], but it was later amended[5] to an adjacent form requiring the five-membered cyclic phosphorane intermediate or transition state to span two basal positions of a trigonal bipyramid, and therefore it is unlikely to be correct[3,6]. A number of other adjacent mechanisms have been suggested that use as a general base either a group on the enzyme[2,7,8], the 2-oxygen of the nucleoside[9], or both[10]. More recently, another in-line mechanism has been proposed[11], but although it is based on X-ray and NMR evidence of the mode of binding of dianionic inhibitors, the arguments, particularly for the second step, are not compelling. We report here an unambiguous determination of the geometry of the second step that enables us to identify the correct mechanism.

The key to the successful resolution of the geometry was the isolation by Eckstein[12,13] of the two diastereoisomers of uridine-2′,3′-cyclic phosphorothioate shown in Fig. 2. The cyclic thiophosphate (isomer a) was hydro-

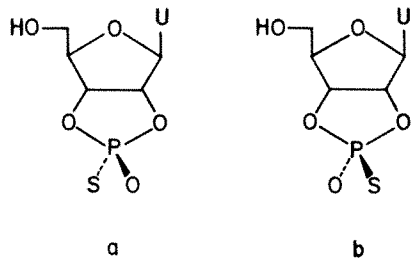

Fig. 2. Two diastereoisomers of uridine-2′,3′-cyclic phosphorothioate[12,13]. Isomer a shows[12,13] the same K_m towards ribonuclease as uridine cyclic phosphate, but v_{max} is lower by a factor of 5. We assume that enzymic hydrolysis gives only the 3′-monoester, as found for the related phosphate.

lysed at *p*H 7 by pancreatic ribonuclease A in water enriched in ^{18}O, and the resulting monoester was re-cyclized by treatment with diethyl phosphorochloridate in pyridine solution to give a mixture of the two isomers a and b (see Fig. 3). The preference rules predict[6] that the ring closure would be in-line, because in these basic conditions the relatively electropositive anionic groups would preferentially remain in basal positions (see Fig. 4) and pseudorotation would be inhibited[2]. If the geometry of the enzymic ring opening is also in-line, then the isomer a that is produced should contain no excess ^{18}O, while isomer b should show the incorporation of one equivalent of ^{18}O from the water. A detailed analysis of the possible effects of pseudorotation on the enzymic reaction reveals that scrambling of the isotopic purity can occur if both of the ring oxygens are allowed to occupy basal positions at the same time, or if free cyclic ester is reformed from pseudorotamers below the dotted line (see Fig. 5). Both possibilities are considered unlikely, the first on grounds of ring strain[6] and the second on the basis of the following argument. There are three pseudorotamers below the dotted line: loss of sulphur from A would not give starting material and does not occur[12,13]; loss of ^{18}O from B would be the reverse of an adjacent mechanism for the addition of water and yet this diagram is for an in-line mechanism; loss of ^{16}O from C would imply that more than one oxygen from the solvent could be incorporated into the ring opened material and this can be excluded[14]. It should be noted that product formation from any of the rotamers always gives the same geometry in the resulting 3′-monoester.

As a check on the arguments given above, a control

Table 1. HYDROLYSIS OF URIDINE-2′,3′-CYCLIC PHOSPHOROTHIOATE (ISOMER a) BY RIBONUCLEASE A

Isomer isolated after ring closure (and purity)	Percentage incorporation: Expected if ring opening was adjacent (per cent)	Expected if ring opening was in-line (per cent)	Found (per cent)
a (about 90 per cent)	86	14	6
b (about 75 per cent)	28	72	70

The isomeric purity of the starting material was assumed to be 95 per cent but may have been higher. Water used in the hydrolyses contained between 4 and 5 per cent ^{18}O; analysis of the thiophosphate for ^{18}O incorporation was carried out by pyrolysis with mercuric chloride and cyanide[15], followed by mass spectrometric determination of the carbon dioxide produced on an isotope ratio machine (Consolidated 401). The identity of the peaks was checked at high resolution on an MS-902 spectrometer.

experiment was done using hydroxide ion (enriched in ^{18}O) for the initial ring opening. (The probable formation of a mixture of 2′ and 3′-monoesters does not invalidate the arguments presented here.) In this case the ring opening and ring closure should both be in-line, and the incorporation of ^{18}O in the product was indeed near zero for isomer a and about 85 per cent of the theoretical value for isomer b. Allowance was made for the presence of about 10 per cent isomer b in the starting material and in the isomer a isolated after ring closure.

The results, given in Table 1, show that for this compound the enzymic hydrolysis and the ring closure proceed with the same geometry. We conclude that the second step in the action of ribonuclease A is in-line, and that all mechanisms so far proposed for the ring opening that require one group to act first as a general base toward

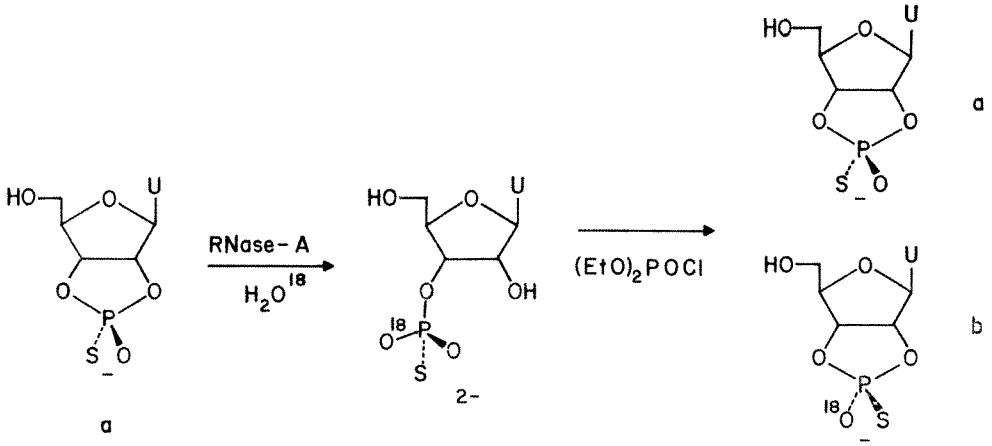

Fig. 3. The method used to determine the geometry of the ring opening step. This diagram shows an in-line mechanism.

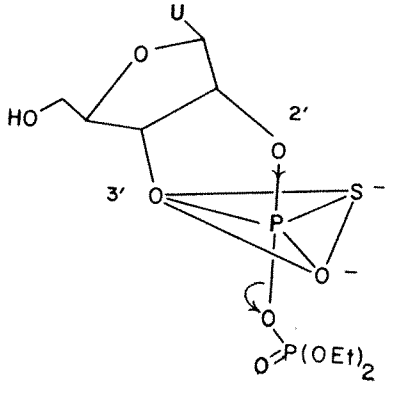

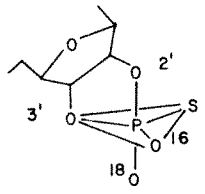

Fig. 4. Loss of diethyl phosphate gives uridine cyclic phosphorothioate by an in-line meachnism[2,6]. Pseudorotation is inhibited.

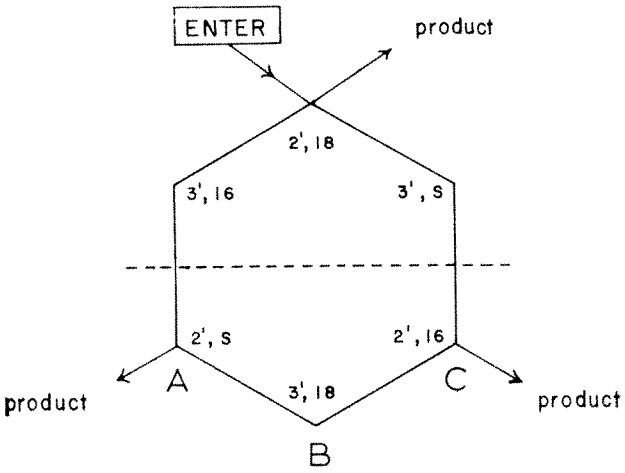

Fig. 5. A pseudorotation diagram[16] for the enzymic hydrolysis of uridine cyclic phosphorothioate. This diagram assumes an in-line mechanism, but a similar diagram can be drawn for an adjacent geometry. The apices of the hexagon represent individual pseudorotamers, the structures of which are denoted by the apical groups[16]. The structure shown is thus (2',18).

the attacking water molecule and then as a general acid toward the 2'-oxygen are unlikely to be correct.

We thank Drs D. B. Denney and D. Z. Denney and Drs G. Dudek and J. Wright for running ^{31}P NMR spectra, and we also thank the US National Institutes of Health for partial support of this research.

In vivo Cortisol Action on RNA Synthesis in Rat Liver Nuclei and Mitochondria

Various mechanisms have been proposed for the action of hormones in cells. One is a cytoplasmic mechanism involving mitochondria[1,2]; a second implies that cytoplasmic protein receptors act as sites[3] for the hormone action; a third proposes that the nuclei act as a primary site for hormone action[4,5]. We now demonstrate that cortisol, when used for brief periods and in physiological doses, increased the RNA polymerase activity of rat liver mitochondria. In these conditions nuclear RNA synthesis was not affected. Hormone treatment for longer periods or treatment with large doses for short time periods increased the nuclear RNA polymerase activity and suppressed the mitochondrial enzyme.

Charles River female rats (140–160 g) were bilaterally adrenalectomized and ovariectomized and will be referred to in the text as adrenalectomized rats. Animals were kept on 1 per cent NaCl and fox chow *ad libitum* in a light and temperature controlled room. All autopsies were performed at 0900 h. Livers were immediately excised and homogenized in cold 0·25 M sucrose.

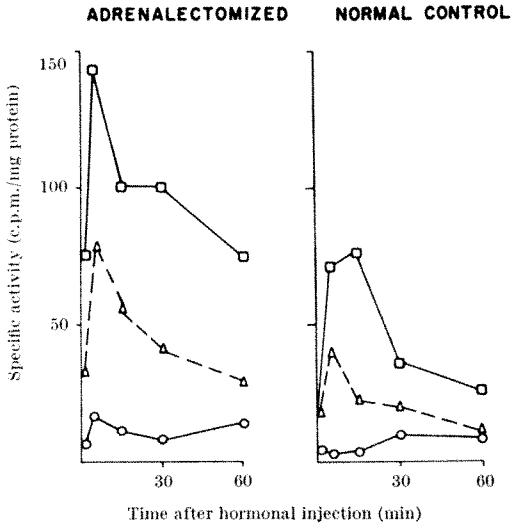

Fig. 1. 6 days after operation, rats were injected (0·25 mg/100 g with 1,2-^{3}H-hydrocortisone (specific activity 18·2 Ci/mmole, NEN, diluted with unlabelled cortisol to a final concentration of 1·25 mg/ml.) and autopsied at the indicated times. Nuclear mitochondrial and ribosomal pellets were extracted and counted as described[10]. Sham operated rats were used as controls. Measurements from at least two rats were made after each time interval. ○—○, Nuclear fraction (2,500*g*); △- - -△, mitochondrial fraction (9,000*g*); □—□, ribosomal fraction (105,000*g*).

1,2-^{3}H-Hydrocortisone (specific activity 18·2 Ci/mmole, New England Nuclear, diluted with unlabelled hydrocortisone to a final concentration of 1·25 mg/ml.) was used in the hormone incorporation experiments. Animals were injected once intraperitoneally with 0·5 μCi/100 g body weight with a hydrocortisone concentration of 0·25 mg/100 g. In all other experiments, cortisol (11β,17α,20-trihydroxypregn-4-ene-3,20-dione, Sigma) was dissolved in 95 per cent ethanol and diluted with an equal volume of distilled water. Animals were injected intraperitoneally with the specified dose or vehicle.

Mitochondria were separated by centrifugation[6] and washed three times with 0·25 M sucrose. The protein content of the various fractions was estimated[7] and adjusted to 2–4 mg protein/50 μl. *In vitro* RNA polymerase was assayed[8]. At various intervals aliquots were pipetted on disk filter paper (Whatman No. 3) and processed as described by Bollum[9].

Fig. 1 represents the specific activity (c.p.m./mg protein) of cortisol binding to the subcellular components.

A rapid incorporation is found in every fraction and this reached a peak at 5 min. The decline of incorporation after 5 min was rapid in the mitochondrial fraction and more gradual in the nuclear fraction. *In vitro* studies of the effect of cortisol on rat liver nuclei gave similar results[11]. Other studies have also shown an association of cortisol[2], as well as oestradiol[10,12], progesterone[13] and testosterone[14] with the mitochondria. There are reports, however, that show only a small degree of cortisol binding to the mitochondrial fraction[15,16]: data were reported as an absolute percentage of incorporation rather than on a protein or nucleic acid basis. Nevertheless, these differences might be due to various factors such as the dosage of hormone, the sex of the animals, or the time after hormone injection. Other reports have dealt with these variables[16–18]. For example, high hormone dosage has been shown to suppress steroidal incorporation into the mitochondrial fraction of guinea-pig liver and kidney[17]. The dosage used by us minimized this effect.

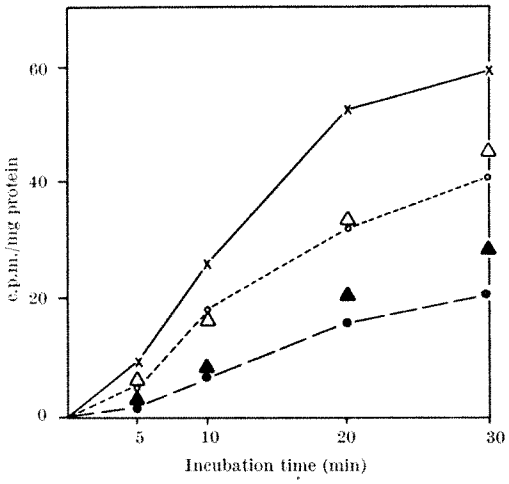

Fig. 2. Adrenalectomized ovariectomized rats were injected intraperitoneally 7 days after operation with 0·5 mg cortisol/100 g and autopsied 15 min, 1, 4 or 8 h later. The ability of nuclei and mitochondria to incorporate acid soluble ^{14}C-GTP into the insoluble fraction was tested *in vitro* at 37° C. Results are from mitochondrial fractions and are expressed as c.p.m./mg protein (2–4 mg mitochondrial protein per assay were used as the enzyme source). Each point represents the mean of two separately run assays. There was no significant difference between controls and the nuclear fractions. ● – – ●, RNA polymerase activity of liver mitochondria from non-treated controls; ▲ – – ▲, from rats 8 h after cortisol injection; △ - - - △, from rats 4 h after injection; × — ×, from rats 1 h after injection; ○ - - - ○, from rats 15 min after injection.

The *in vitro* RNA polymerase activity of the adrenalectomized rat liver mitochondria was studied after a single injection of 0·5 mg cortisol/100 g body weight. Fig. 2 represents a time course study of animals killed at various times after injection. After an incubation of 30 min, the increase in activity ranged from 40 to 200 per cent depending on the length of the initial hormone treatment. Mitochondrial RNA polymerase activity increased 200 per cent if the animals were injected with 0·5 mg cortisol 1 h before autopsy. The enzyme activity of mitochondria isolated from livers 15 min or 4 h after hormone injection was twice that of the controls, whereas 8 h after the hormone injection there was only a 40 per cent increase. At this dosage no effect on nuclear RNA polymerase activity was detected.

The effect of varying the dosage of cortisol while maintaining the time between injection and autopsy constant (at 60 min) on mitochondrial RNA polymerase activity from adrenalectomized rats is shown in Fig. 3. The activity was about twice that of the controls when 0·5 mg of cortisol was injected, whereas a 67 per cent increase was found after injection of 2 to 4 mg. Injection of 8 mg/100 g caused no significant increase in activity. By contrast,

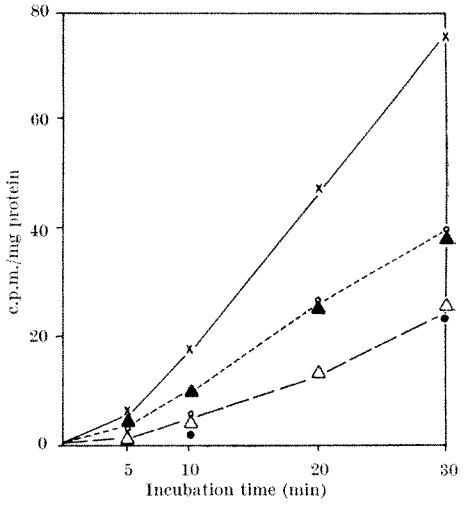

Fig. 3. 0·5, 2, 4 and 8 mg cortisol/100 g were injected intraperitoneally into adrenalectomized ovariectomized rats. Autopsy was performed 1 h after injection and RNA polymerase activity of liver nuclei and mitochondria was tested *in vitro* (see legend to Fig. 2). Results are from the mitochondrial fraction. There was no significant difference between the non-injected controls and the nuclear fraction. ● – – ●, Non-injected controls; △ – – △, 8 mg cortisol/100 g.; ○ - - - ○, 4 mg cortisol/100 g; ▲ - - - ▲, 2 mg cortisol/100 g; × — ×, 0·5 mg cortisol/100 g.

no dose in this range (0·5–8·0 mg/100 g) had any effect on nuclear RNA polymerase activity 60 min after injection of cortisol.

When cortisol (0·5 mg/100 g) was injected 4 h before autopsy (Fig. 4) a 50 per cent increase in the mitochondrial RNA polymerase activity was observed. Larger doses had no appreciable effect. On the other hand, Fig. 5 shows a 45 per cent increase in activity in nuclei isolated from adrenalectomized rat liver 4 h after injection of 4 mg cortisol/100 g, in agreement with the findings of Barnabei *et al.*[19]. Others[20] have reported a higher percentage increase in nuclear RNA polymerase activity, possibly because of the use of rats which had been both adrenalectomized and ovariectomized, rather than rats that were only adrenalectomized[20]. Another explanation is that we used whole nuclei in 0·25 M sucrose rather than the purer nuclear fraction that others have used[19,20].

Our previous work[21,22] has shown that mitochondrial DNA synthesis is stimulated earlier and to a greater

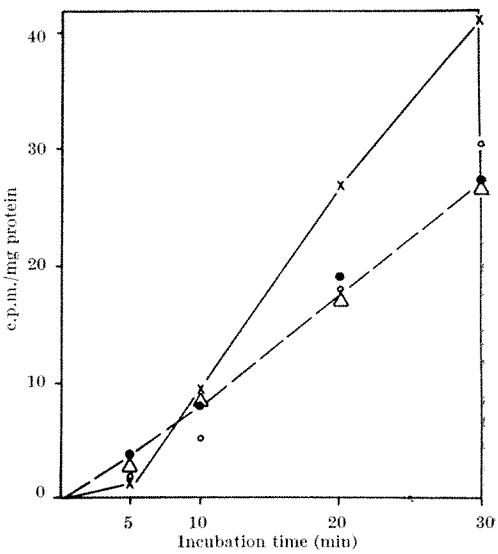

Fig. 4. 0·5, 4 and 8 mg cortisol/100 g were injected intraperitoneally into adrenalectomized ovariectomized rats. Autopsy was done 4 h after injection. Mitochondrial RNA polymerase activity, see legend to Fig. 2. ● - - - ●, Non-injected controls; △ - - - △, 8 mg cortisol/100 g; ○ - - - ○, 4 mg cortisol/100 g; × — ×, 0·5 mg cortisol/100 g.

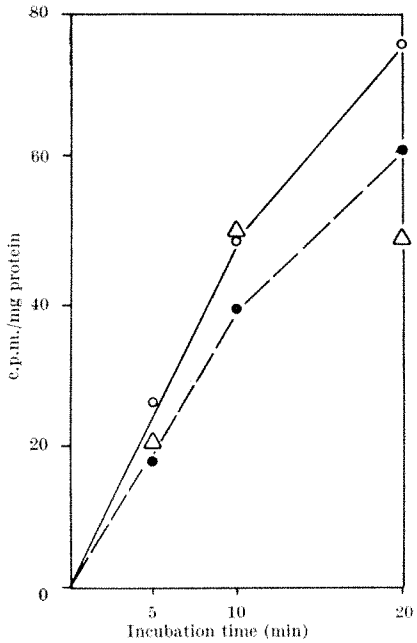

Fig. 5. RNA polymerase activity of rat liver nuclei 4 h after cortisol injection with 4 and 8 mg cortisol/100 g. ●- - -●, Non-treated controls; △, 8 mg cortisol/100 g; ○—○, 4 mg cortisol/100 g.

extent than is nuclear DNA synthesis after partial hepatectomy. This study indicates that mitochondrial RNA synthesis responds earlier and at lower doses of cortisol than does nuclear RNA synthesis. Consideration of these results in relation to specific structural changes in mitochondrial DNA of certain malignant cells[23] leads us to suggest that the study of mitochondrial nucleic acid metabolism will throw light on the regulation of nuclear nucleic acid metabolism[24].

Note added in proof. A recent report by Fu Li Yu and P. Feigelson (*Biochim. Biophys. Acta*, **213**, 134; 1970) confirms our results that, after hormone treatment, rat liver mitochondrial RNA synthesis increases at a faster rate than nuclear RNA synthesis.

Strontium-90 and Infant Mortality in Canada

Sternglass and his associates[1-4] have claimed that strontium-90 in fallout from atomic tests has produced and continues to produce great numbers of foetal and infant deaths. We have now tested on Canadian data the reported finding[5,6] that infant mortality in various states of the US closely paralleled the level of strontium-90 in cows' milk from that same state.

In this analysis, both strontium-90 level and infant mortality are expressed in a special way. Strontium-90 is given as a four year moving average. Why the basis of this should be four years is not clear, but if, as Sternglass believes, strontium-90 acts by producing lethal mutations in the germ line of parents some kind of moving average or cumulative dose is appropriate.

Infant mortality is expressed as "per cent excess infant mortality". This variable originates with an observation by Sternglass (and no doubt others) on the manner in which infant mortality has declined in the United States. When plotted on a logarithmic scale, infant mortality can be seen to have decreased in nearly linear fashion between 1935 and 1950 (see curve for US in Fig. 3). If a linear least-squares line is fitted to the data for this period and extrapolated to recent years, the observed mortality for every year since 1950 lies above the line. Percentage excess infant mortality is defined as the difference, expressed as percentage of total mortality, between the least-squares line calculated from 1935 to 1950 and the observed mortality.

Sternglass computed the percentage excess infant mortality for every state and year in which measurements of strontium-90 in milk are available. He gives plots for six states, said to be "typical", in which strontium-90 and excess mortality increase together in striking fashion.

We have retained Sternglass's definitions of both variables and have made a computer program to compute the 1935–50 least-squares line and from that percentage excess infant mortality. Another program calculates the four year moving average of strontium-90. The program for excess mortality was checked on a set of data supplied by Dr Sternglass and produced the same result as he had found.

In Canada, there are nine provinces for which adequate data on both infant mortality and strontium-90 are available. For each of these we have calculated the least-squares line best fitting the mortality from 1935 to 1950 and, from this, the percentage excess infant mortality. The percentage excess infant mortality, together with the four-year moving average of strontium-90, is shown for each province in Fig. 1.

The strontium-90 levels in Canada are somewhat higher than those in the US, yet it will be seen that strontium-90 appears to have had no effect on mortality. We have noticed that in Canada use of the period 1945–55 as the interval for which to calculate the least-squares line would give a result more in accord with the plots Sternglass has published. At the urging of Dr Sternglass, we have pursued this line of endeavour, and the conclusion is unfavourable to his hypothesis. He tells us that recently he has discovered that the base period 1946–55 is the most appropriate one, not only for Canada but for other countries, and he is re-doing many of his calculations and plots for various countries on this basis. We have, accordingly, recalculated our result.

When we re-do the calculation using 1946–55 as the base period, excess infant mortality in some provinces does appear to rise during the period of atomic testing. There is, however, no real association between the two variables (Fig. 2). There are six provinces for which data are available from 1960 to 1965, with 1965 corresponding roughly to the peak of strontium-90 level. It is evident from the plot that, among these provinces, a large rise in strontium-90 does not tend to go with a large rise in excess mortality.

If anything, the reverse is true. There is a slight negative association between the amount of change in the two variables over this period. That is, the provinces with the most fallout have the least increase in excess mortality.

Is there reason to think that the association asserted by Sternglass does, nevertheless, hold for the US? An analysis of the US data by the method just used for Canada is very much to be desired. Unfortunately, we have been unable to obtain a full set of data on strontium-90 of the sort necessary to make a plot like that in Fig. 2. The only material we have is a set of data sent to us by Dr Sternglass covering the years 1960–67. If we take 1966 as the peak year for strontium-90, we are able to calculate the four-year moving average of strontium-90 for only the years 1963–66. The result is nonetheless informative. The percentage excess mortality for these same years has been calculated using Sternglass's original period of 1935–50 as the basis for the least-squares line; and the result is as before. The strontium-90 and the mortality variables in the various States do not rise together. If anything they show a slight negative association (regression coefficient $b = -0{\cdot}81$).

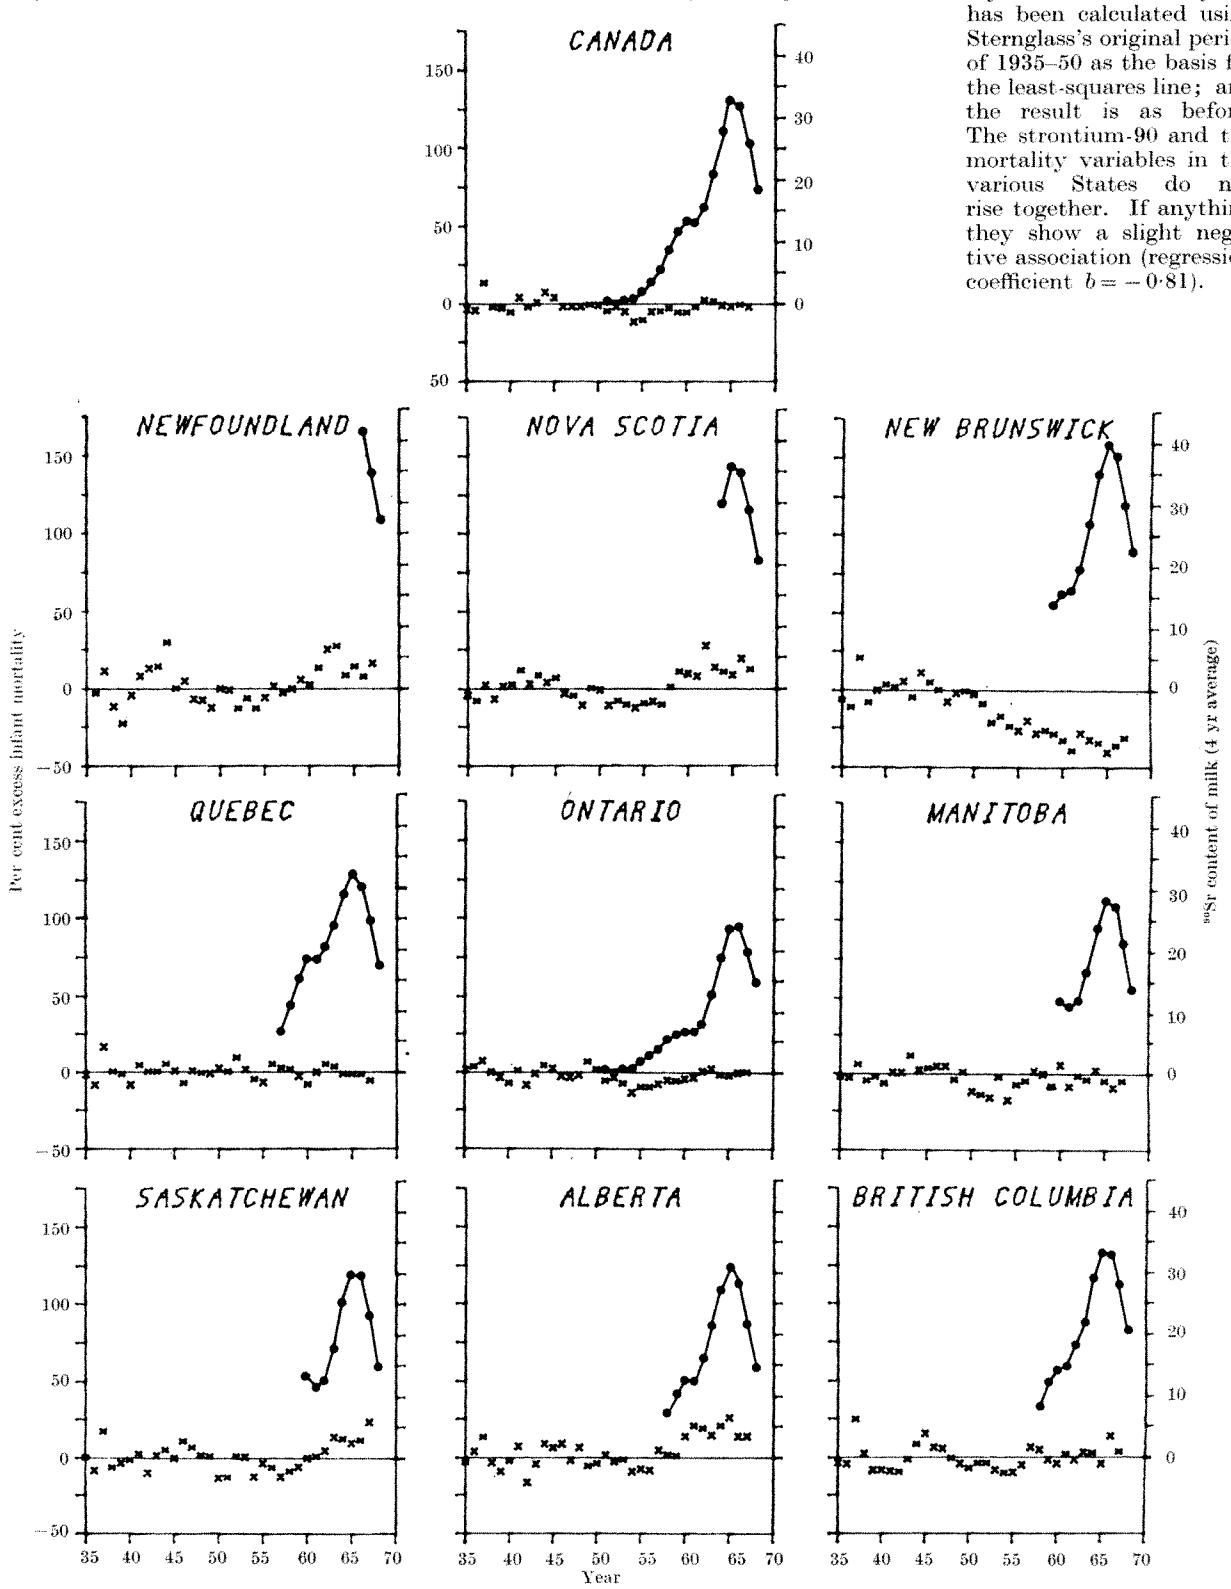

Fig. 1. Canadian infant mortality as related to strontium-90 in cows' milk. For definition of "per cent excess mortality" see text. Units of strontium-90 are picocuries per litre. ×, Excess infant mortality; ●, strontium-90 level in milk.

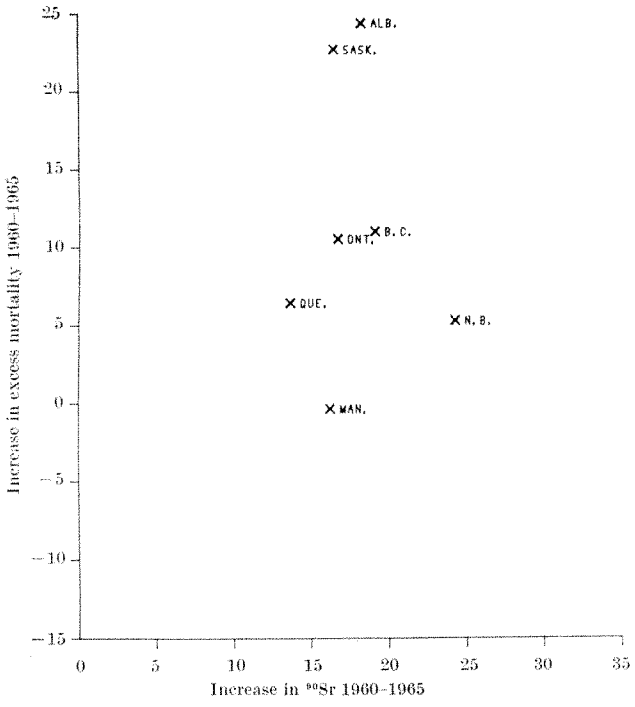

Fig. 2. Change in infant mortality and change in strontium-90 level, calculated using 1946–55 as the basis for the least-squares line. (Least-squares estimate of slope is $b = -0{\cdot}12$.)

Influence of Hydrostatic Pressure on the Reversible Polymerization of Fibrin Monomers

The conversion of fibrinogen to fibrin, which is the last stage of the complex process of blood coagulation, is composed of three successive reactions[1]: an enzymatic hydrolysis by thrombin of four arginyl-lysyl bonds per molecule of fibrinogen, yielding a fibrin monomer; a spontaneous polymerization of monomers to form a gel or fibrin clot; and an enzymatic transamidation by fibrin stabilizing factor (factor XIII or fibrinase) between ε-amino groups of lysyl and glutaminyl side chains. The mechanism of the reversible polymerization of fibrin monomers remains largely unknown, although it can be studied separately because fibrin monomers can be stabilized in acidic media of high ionic strength such as 1 M NaBr, *p*H 5·3[2].

The hypothesis of hydrogen bonding between ionizable groups, in which histidyl functions as acceptor and tyrosyl or lysyl as donors, as proposed by Sturtevant *et al.*[3], accounts for the depolymerizing effect of dilution, of slight temperature increase and of salts and urea. It also explains the *p*H range of polymerization (between 5·5 and 10·5), the *p*H evolution during the reaction (proton liberation below *p*H 7·5) and the inhibiting effect of chemical blocking of histidyl and tyrosyl residues. The only real shortcoming of this hypothesis is its failure to account for the magnitude of the heat evolution during polymerization[4]. It seems that additional heat evolving reactions such as hydrogen bonding between non-ionizable groups, ion pair bonding, hydrophobic bonds or conformational changes should also be involved. Up to now, however, no sufficient independent evidence for either of those additional reactions has been presented.

The origin of the heat evolution in reversible fibrin polymerization has become an interesting problem since a number of other cases of exothermic protein polymerizations, including flagellin, β-lactoglobulin and lactic dehydrogenase, have been discovered.

A study of the influence of hydrostatic pressure on the polymerization equilibria gives the sign and magnitude of the volume increment, which is dependent on the nature and the number of the interactions involved in polymerization. Volume changes during polymerization have been noted before, for example in tobacco mosaic virus protein[5] and in myosin[6].

Bovine fibrinogen was prepared according to the method of Blombäck and Blombäck[7]; fibrin monomers were prepared according to Donnelly[2] as modified by Endres[4].

A technique for observing association and aggregation reactions of proteins by means of light scattering measurements under high pressure has recently been developed by Putzeys and Vaneghem (unpublished thesis). We were able to use the apparatus and technique in the Laboratory of Biochemistry I. Light scattering measurements were taken at 90° and under pressure up to 3,200 kg/cm². Temperature variations resulting from application of pressure were prevented by a water jacket, maintained at 25° C.

Fibrinogen and fibrin monomer solutions showed no change in light scattering under pressure up to 3,200 kg/cm² except for a small stepwise change during the application of pressure, caused by deformation of the windows in the optical path (Fig. 1A).

Intermediately polymerized fibrin monomer solutions of 10 mg/ml. in 1 M NaBr, 0·05 M acetate buffer, with a *p*H varying from 5·75 to 6·15, showed a large decrease in light scattering under pressure (Fig. 1B–E) and were apparently already completely depolymerized under a pressure of 2,500 kg/cm², for after equilibration a further increase did not change the amount of scattered light. The polymerization–depolymerization reaction was always completely reversible. The influence of the concentration

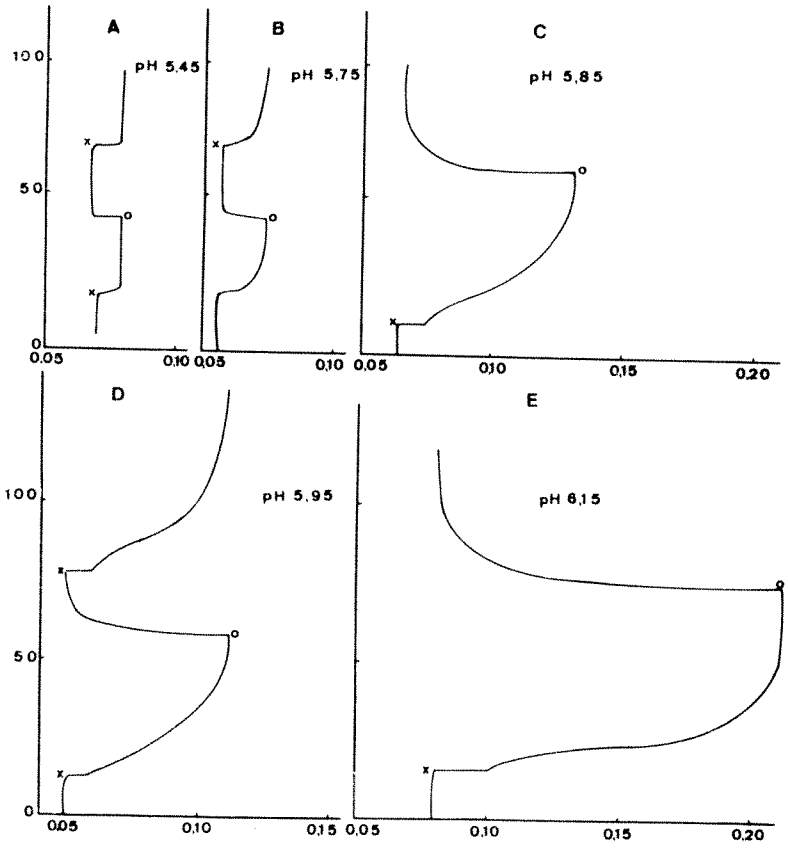

Fig. 1. Influence of pH on the polymerization of fibrin monomers in 1 M NaBr; abscissa, photomultiplier current in μA; ordinate, time in min; ○, application of pressure of 2,500 kg/cm²; ×, release of pressure. The solutions were initially depolymerized by application of pressure.

of protein on the light scattering changes under pressure is shown in Fig. 2. Turbid clots[8], prepared by 20 fold dilution of 10 mg/ml. fibrin monomer solutions in phosphate buffer ($I = 0{\cdot}2$, $p\mathrm{H} = 6{\cdot}0$), depolymerized equally well under a pressure of 2,500 kg/cm².

Because the polymerization is very pH sensitive and the pH of the acetate buffer decreases under pressure (about 0·4 pH units at 3,000 kg/cm²) it was tested whether the depolymerizing effect of pressure could be ascribed to pH changes. The experiments were therefore repeated in a 0·05 M ammonium acetate buffer (decrease of about 0·1 pH units at 3,000 kg/cm²) and in 0·05 M MES (N-morpholino - ethane - sulphonic acid) buffer (increase of about 0·25 pH units at 3,000 kg/cm²). In all cases an apparently complete depolymerization was obtained at 2,500 kg/cm².

Finally, it was tested whether the pressure effect could be ascribed to an alteration of the protein during the preparation of monomers. Native plasma, diluted with buffer to a concentration of 1 mg fibrinogen/ml. and clotted with thrombin, behaved identically under pressure.

On the basis of the complete reversibility of the depolymerization and polymerization reactions and in view of the fact that the phenomenon is the same in buffers with different pH dependence on pressure, we conclude that the polymerization is accompanied by an increase in volume. This volume increase is not explained by the hypothesis of hydrogen bonding between histidyl and tyrosyl or ε-amino groups as the only polymerization mechanism for this reaction in the pH range investigated should be accompanied by a volume decrease (resulting from hydrogen bonding and from electrostriction around the liberated protons).

In fact, our results indicate that during polymerization an additional interaction occurs with a significant volume increase sufficient to overcome the volume decrease due to hydrogen bonding and electrostriction. This seems to point in the direction of the existence of additional hydrophobic bonding or ion pair bonds (salt linkages)[9]. The role of hydrophobic bonding seems to be small in view of the depolymerizing effect of temperature and electrolyte concentration. Attempts to show the presence of hydrophobic sites on the surface by binding the ligand

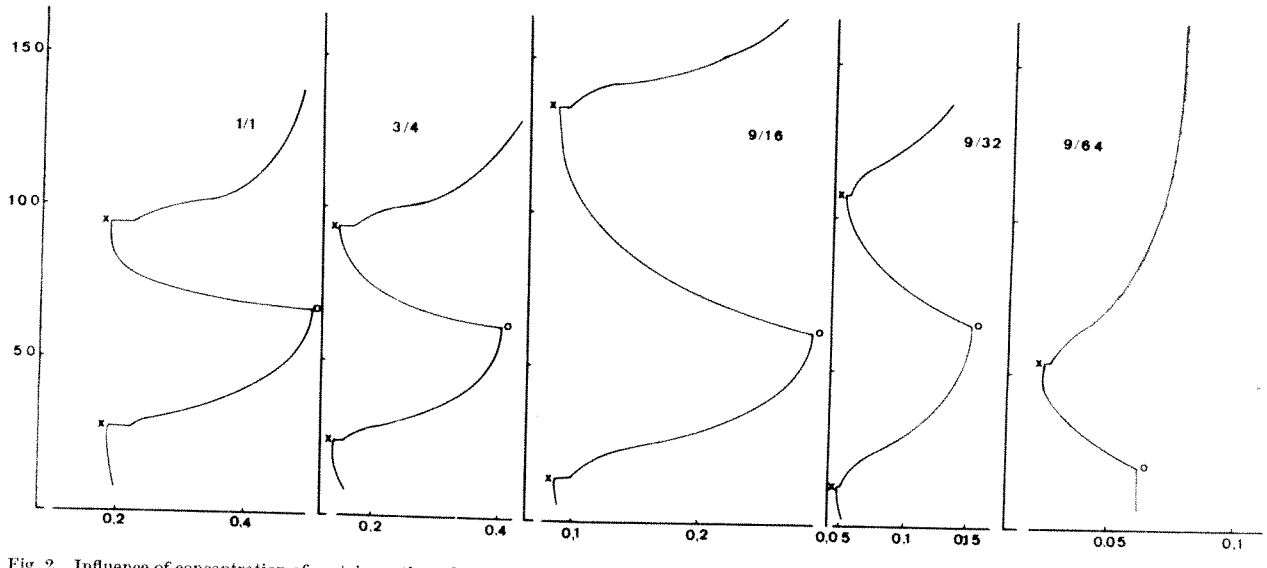

Fig. 2. Influence of concentration of protein on the polymerization in 1 M NaBr, pH 6·1. Abscissa, photomultiplier current in μA; ordinate, time in min; ○, application of pressure of 2,500 kg/cm²; ×, release of pressure. The solutions were initially depolarized by application of pressure. Dilution 1/1 = 10 mg fibrin monomers per ml.

ANS (1-anilo-8-naphthalene sulphonate)[10,11] were unsuccessful. Further studies to estimate the volume increase per link by quantitative determination of the effect of pressure on the successive polymerization constants will be undertaken.

We thank Professor P. Putzeys for the use of his special equipment and Dr A. Persoons and Dr K. Heremans for their advice. We also thank Mr F. Decock for his technical assistance.

In vitro Production of Nucleolar Channel System by Progesterone in Human Endometrium

Electron microscope examination of normal human endometrium during the midsecretory phase of the menstrual cycle demonstrates that the nucleolus of the epithelial cell differentiates into an organelle variously termed a nucleolar canalicular system[1], a nucleolar basket[2] or a nucleolar channel system[3]. Such a structure appears if ovulation has occurred. Nucleolar baskets have been seen as early as the sixteenth day of a normal 28 day cycle. After this they may increase in number, reaching a maximum around the twentieth day and then disappear, not being found later in the cycle. They have not been seen in the proliferative phase of the cycle or in early pregnancy.

This system seems to be a unique form of nucleolar differentiation having been observed in human glandular endometrial cells and in no other tissue. It consists of an involved labyrinth of channels coursing through a more dense homogeneous matrix (Fig. 1). Electron opaque 150 Å particles are arranged in a regular fashion around the periphery of the total channel mass but may also surround the individual channels (our unpublished results).

Previous attempts to demonstrate the specific physiological effect of progesterone by means of organ culture were frustrated by the induction of secretory changes in the endometrial cell in the control culture[4]. Electron microscope examination of such organ cultures failed to show nucleolar channel systems[5]. Using organ culture of proliferative human endometrium it has recently been shown[6,7] that progesterone does act directly on the epithelium to convert proliferative to secretory endometrium. Thus the effects observed *in vivo* could be mimicked *in vitro*. This conversion was specifically due to progesterone and was not produced in the control cultures, in cultures with oestrogen alone or with cortisol. We undertook this study to find out whether nucleolar differentiation can be induced by progesterone in organ cultures of proliferative endometrium.

Specimens were obtained aseptically from normal women by endometrial biopsy on the tenth day of the menstrual cycle. A small piece was processed for electron microscopy and another was examined histologically. The remainder of the endometrium was cut into pieces 1–2 mm³. Each of six pieces was placed on 'Millipore' filter paper resting on agar enriched with TC 199 medium to which 10 per cent calf serum and 10 μg/ml. insulin had been added. In addition to control cultures, cultures containing progesterone (1 μg/ml. and 10 μg/ml.), medroxyprogesterone acetate (1 μg/ml. and 10 μg/ml.), oestradiol (10 μg/ml.) or oestradiol (10 μg/ml.) plus progesterone (10 μg/ml.) were prepared. These were incubated at 37° C in a moist atmosphere of 95 per cent oxygen and 5 per cent CO_2. Specimens were examined both histologically and by electron microscopy after 48 and 96 h. For electron microscopy, a small portion of the tissue was fixed in 3 per cent glutaraldehyde in phosphate buffer (*p*H 7·0) at room temperature for 1 or 2 h. After re-fixation for 1 h in 1 per cent veronal buffered osmium tetroxide and subsequent dehydration, the specimens were embedded in 'Epon 812'. Thin sections were double stained with uranyl acetate and lead citrate and examined in an Hitachi HU-11B electron microscope. At least two tissue blocks containing representative samples of endometrium were examined from each specimen.

The histological appearance of the control cultures resembled that of the original proliferative endometrium. Oestrogen produced no significant change. The addition of progesterone produced the changes characteristic of secretory endometrium, first subnuclear deposition of glycogen, then secretion of the glycogen into the lumen of the glands.

Electron microscope examination of the original specimen showed the characteristic appearance of proliferative endometrium (ref. 8 and our unpublished data). No nucleolar channel systems were seen. Extensive search failed to reveal nucleolar channel systems in the control cultures and none were found in the cultures exposed to oestradiol. Characteristic nucleolar channel systems were produced in the cultures containing progesterone (Fig. 2). They were found after 48 and 96 h at both progesterone concentrations but it was not possible to quantitate the results in terms of length of exposure to, or concentration of, progesterone. Although our results suggest that differentiation may be accelerated *in vitro*, such a conclusion is not justified without further study. Nucleolar baskets were also produced in the culture

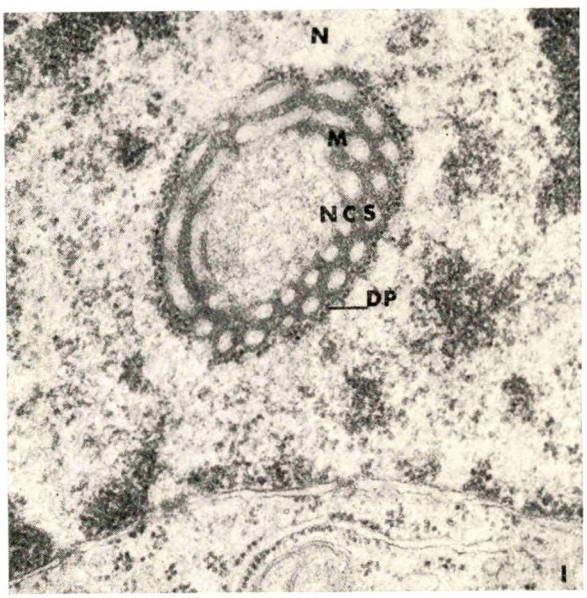

Fig. 1. Electron micrograph of endometrial epithelial cell from a biopsy specimen taken on the eighteenth day of a normal 28 day cycle. A nucleolar channel system (NCS), characteristic of secretory stage endometrium, is seen within the nucleus (N). The channels course through a dense matrix (M). Dense particles (DP) are seen at the periphery of the nucleolus. (×24,375.)

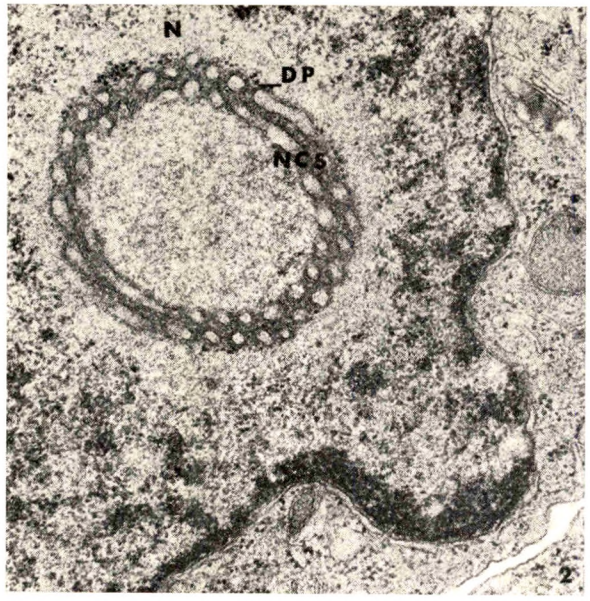

Fig. 2. Electron micrograph of epithelial cell from 10 day normal human endometrium cultured for 96 h in a medium containing 10 μg/ml. progesterone. Comparison with Fig. 1 demonstrates that a similar nucleolar channel system (NCS) is present within the nucleus (N) although the biopsy specimen was in the proliferative stage. Dense particles (DP) are at the periphery of the nucleolus. (×24,375.)

containing oestrogen and progesterone, demonstrating that oestrogen is not inhibitory to nucleolar differentiation. It would be of interest to determine whether greater concentrations of oestrogen would counteract the influence of progesterone. Cultures containing 1 μg/ml. medroxyprogesterone acetate also showed baskets, confirming the physiological action of this compound.

These results illustrate a close relationship between progesterone and the development of nucleolar channel systems in glandular cells of human endometrium. The combined technique of organ culture and electron microscopy offers a means of further exploring the effects of progestational steroids to help elucidate their mode of action more precisely.

This research was supported by the Connecticut Division of the American Cancer Society, the Anna Fuller Foundation and by the Ford Foundation. The medroxyprogesterone acetate was supplied by the Upjohn Company.

'Tuftsin': a Natural Phagocytosis Stimulating Peptide

WE have shown in this laboratory that a specific cell bound leucophilic γ-globulin fraction, leucokinin, is essential for maximal stimulation of the phagocytic activity of the blood neutrophilic leucocyte[1,2]. We now report that the whole stimulatory effect of leucokinin can be ascribed to a single peptide fragment liberated by a specific enzyme in the outer membrane of the neutrophile. We shall refer to this peptide as 'tuftsin' (after Tufts University) and to the enzyme as leucokininase. The peptide 'tuftsin' has been produced *in vitro* from a γ-globulin fraction, PC IV, by treatment with leucokininase. PC IV is prepared by chromatography on phosphocellulose columns[3] and contains all the leucokinin activity of serum γ-globulin[2].

To prepare leucokininase, polymorphonuclear leucocytes from 100 ml. of human or dog blood were isolated on glass columns[4]. These were lysed in 5 ml. of 0·34 M sucrose and the cytoplasmic granules separated out in the supernatant by centrifugation[5]. The sedimented membranes and nuclei, about 0·3 ml., were washed four times in 5 ml. of 0·1 M phosphate buffer (*p*H 6·7). This was followed by homogenization in a 'Teflon'–glass homogenizer, after which the membrane was floated in 2·1 M sucrose at 30,000 r.p.m. for 16 h in a Spinco 'SW39' rotor. The membrane portion so isolated was then washed in phosphate buffer and broken further by high frequency sound (Biosonic, microtip; setting 20; 2 min). The preparation of neutrophilic leucocytes should be practically free of erythrocytes. Red cell membranes similarly treated exhibit strong peptidase activity towards 'tuftsin', thereby destroying its biological effect.

The enzyme has a sharp *p*H optimum at about 6·7; its activity becomes negligible at *p*H 6 and 7·8 and its optimum temperature is around 37° C. At 22° C it has very low activity and at 45° C it is destroyed. Thoroughly washed membrane preparations retain full activity. It does not dissociate readily on standing at 4°–6° C for a week, but is partly solubilized after repeated freeze–thawing. It is presumably present on the outer surface of the membrane, for the intact thoroughly washed cell shows highly active leucokininase.

To prepare the peptide 2–4 μg of membrane protein (leucokininase), 1·0 mg (approximately 6·5 nmoles) of γ-globulin fraction PC IV, are mixed in a final volume of 0·5 ml. of 0·1 M phosphate buffer (*p*H 6·7). This is incubated at 37° C for 60 min. The reaction is stopped by the addition of 4 volumes of 95 per cent ethanol and placed in a water bath at 80° C for 8 min, after which it is cooled. The supernatant containing 'tuftsin' is separated from the precipitate and dried by an air stream. The residue is then washed twice with ethyl ether and dried *in vacuo*. 0·5 ml. of distilled deionized water is added and 0·05 ml., equivalent to 0·1 mg of the original protein, is used for each phagocytosis test. These determinations are carried out in Hanks medium or in buffered isotonic sucrose medium[2]. The stimulatory effect of 'tuftsin' is equivalent to the amount of PC IV from which it is derived. About 0·1 mg of PC IV and its 'tuftsin' equivalent constitute the minimal amounts necessary for maximal *in vitro* stimulation in a total volume of 0·4 ml.[2,6].

PC IV was prepared from commercially available Cohn fraction II γ-globulin and its leucokinin activity was completely precipitable with specific anti-γG serum[2]. PC IV shows only a γG band with immunoelectrophoresis and diffusion against anti-human serum[2,3]. It sediments as a 7S γ-globulin with a symmetrical peak. It shows one band in disc electrophoresis[3]. PC IV so purified was subjected to papain digestion and the Fc and Fab fragments were isolated[7] and tested directly *in vitro*[6]. The phagocyte activity usually expressed as percentage of cells containing bacteria[1,2] was shown to reside only in the Fab fragment. Representative values of several determinations (between three and ten) showed that with 0·1 mg equivalent of PC IV, Fab gave an average value of 48 per cent compared with 18 per cent obtained with Fc and control values of 20 per cent given by the standard reaction mixture alone. Similarly, the heavy and light chains of the parent molecule were studied. These were prepared by reduction and alkylation[8]. Following

leucokininase treatment, 'tuftsin' was extracted with ethanol and assayed for its phagocytic stimulation. All activity resided in the heavy chain which yielded a value of 50 per cent while the light chain gave values similar to the controls. Thus 'tuftsin' seems to be in the amino-terminal portion of the heavy chain in the Fd fragment; it is therefore unlikely that it contains carbohydrate moiety.

The stimulatory effect of 'tuftsin' on phagocytosis is destroyed by incubation for 3 h at 30° C with pronase, subtilisin, carboxypeptidase B and leucinaminopeptidase, using 10 μg protein/ml. in optimal conditions of enzyme action[10]. Similarly, it is destroyed by incubation with soluble supernatants of disrupted leucocytes and membrane preparations from human erythrocytes and rat liver at *p*H 7·0 in phosphate buffer. In all these, phagocytosis was at the level of the controls. 'Tuftsin' is not destroyed by exposure to aeration in the presence or absence of cysteine, treatment at 80° C for 10 min in 80 per cent ethanol, trypsin, chymotrypsin, clostridiopeptidase B, phosphatase, deoxyribonuclease. Phagocytosis values obtained after such treatment were 46 per cent to 50 per cent, about 2·5 times those of the controls. 'Tuftsin' is presumably present only in a small fraction of leucophilic γ-globulin and its *in vitro* activity can be elicited with hormone like quantities. The yield of biologically active alcohol extractable and ninhydrin positive material per mg of PC IV protein is very small. More than 1,000 phagocytosis determinations can be carried out on samples that yield a moderately detectable ninhydrin colour. Purification has therefore been cumbersome and simple contamination from glassware and chemicals makes analysis difficult. It seems likely, however, that 'tuftsin' does not contain cysteine, methionine, tyrosine, phenylalanine or tryptophan. Its great susceptibility to carboxypeptidase B indicates the presence of a basic amino-acid as the carboxyl-terminal residue. 'Tuftsin' has other characteristics in common with polypeptide hormones: it is a highly active and readily dialysable polypeptide; and it is a part of a larger carrier molecule.

'Tuftsin' has been found deficient or absent in one male and three female patients with recurring infections. No stimulation of phagocytosis above the usual control values could be elicited despite repeated testing. Should it turn out that 'tuftsin' can stimulate phagocytosis *in vivo* as it does *in vitro*, it might have some therapeutic application in diseases in which phagocytosis is important.

We thank Drs Michael Miller, A. Dwight Bramble and John W. Smith for supplying us with sera of the patients studied, and Miss Ella Stitt for technical assistance. This work was supported by a grant from the National Institutes of Health, US Public Health Service.

Interaction of Atropine with the Muscarinic Receptor

WE report here the crystal structures of two muscarinic antagonists of acetylcholine, (−)-(*S*)-hyoscine hydrobromide[1] and (−)-(*S*)-hyoscyamine hydrobromide (atropine). Correlation of these two structures and that of quinuclidinyl benzilate hydrobromide[2] shows marked similarities among the three molecules although they are subjected to very different crystal packing forces. This suggests that intramolecular forces impose a preferred conformation on many such antagonist molecules. The structural correlations may be used to derive a set of rules for predicting the conformation relevant to muscarinic antagonism of acetylcholine for many molecules which at first sight are rather dissimilar to atropine (T. J. P., in preparation).

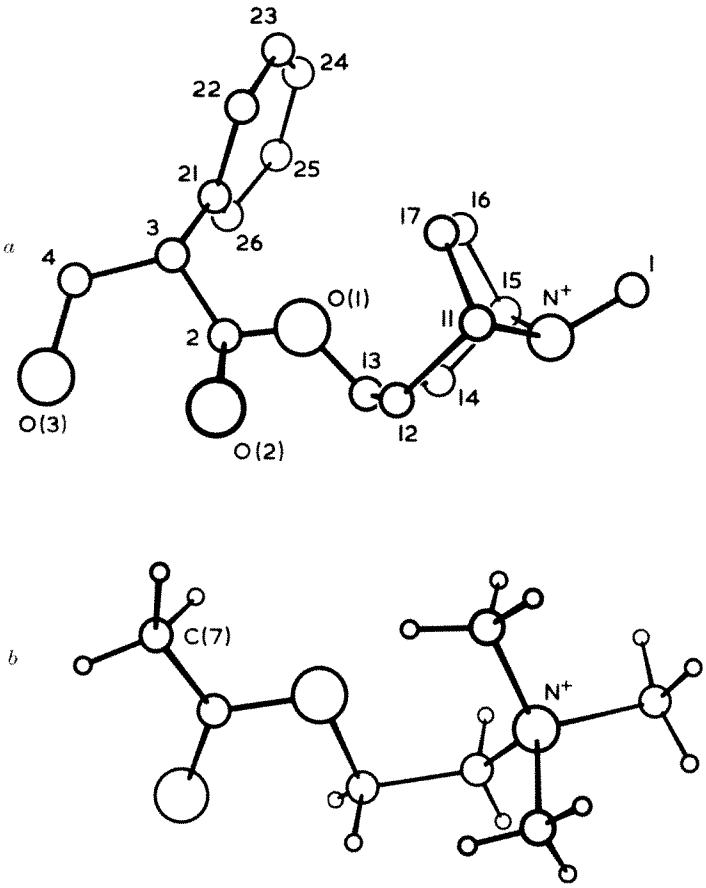

Fig. 1. Molecules of atropine (*a*) and acetylcholine (*b*) in the conformations relevant to interaction with the muscarinic receptor.

The crystal structure of (−)-(*S*)-hyoscyamine hydrobromide was determined by standard methods from diffractometer data and refined by full-matrix least-squares to a present *R* of 0·09. The molecule is shown (Fig. 1*a*) in the absolute configuration corresponding to that of the more potent enantiometer and with an intramolecular hydrogen bond O(3)–H . . . O(2). This bond is not present in the crystal, but the conformation shown is that which correlates best with the other crystal structures. The hydrogen bond has been shown by spectroscopic measurements[3] to exist in solution. This is the only change from the conformation observed in the crystal, which otherwise coincides exactly with the observed conformation of hyoscine and is very similar to that of quinuclidinyl benzilate. The molecule is best described by three planes: that of the benzene ring, of the planar acetoxy group, and of the mirror plane bisecting the tropane fused ring system through N^+ and C(13). The

angle between these last two planes is 35°, which is exactly the mean value found in a survey of secondary esters (P. J. P., in preparation) and the plane of the benzene ring makes an angle of 86° with the plane of the ester group. The corresponding angles in hyoscine are 45° and 89° respectively. The situation in quinuclidinyl benzilate is a little different, but the spatial arrangement of the nitrogen atom, one of the two benzene rings, and the hydroxy group is very similar to that in the other two molecules.

The acetylcholine molecule, in the preferred conformation relevant to interaction with the muscarinic receptor (C. H. Chothia, P. J. P., and T. J. P., in preparation), is shown (Fig. 1*b*) for comparison. The only groups believed to interact with the receptor are the $-N^+(CH_3)_3$ cationic head and the C(7) methyl group, the former by electrostatic and the latter by van der Waals forces. The relationship of the plane containing the C(7) hydrogen atoms to the cationic head is very similar to that of the benzene ring and the charged nitrogen atom in atropine (Fig. 1). The N^+-plane distances are, moreover, very similar (575 and 625 pm respectively). We therefore suggest that both atropine and acetylcholine interact with the muscarinic receptor in similar ways and at the same site. The van der Waals interaction of the C(7) methyl group in acetylcholine is paralleled by the rather stronger interaction of the flat benzene ring in atropine; the charged nitrogen atoms interact with the same anionic site. The criteria distinguishing antagonists from agonists, then, are (*a*) the presence of a lipophilic group capable of stronger van der Waals binding than a methyl group at a similar distance from a charged nitrogen atom, as is C(7) in acetylcholine (this explains the transition in properties from agonist to antagonist as acetylcholine is successively substituted at C(7) by larger alkyl groups); and (*b*) for efficient antagonism, the presence of an auxiliary electrophilic group, O(3)H in the case of atropine, in a suitable spatial relationship to the first two groups. Examination of space-filling models shows that practically all potent muscarinic antagonists satisfy these criteria.

We thank John Cresswell for the figures, Margaret Dellow for programming assistance and the MRC for financial support.

Bicuculline and Inhibition of Crayfish Stretch Receptor Neurones

THE recent reports[1,2] on the antagonistic effect of the alkaloid bicuculline both of the actions of γ-aminobutyric acid (GABA) electrophoretically applied to single neurones and of certain strychnine-resistant inhibitory mechanisms in the mammalian central nervous system have suggested that the effects of this substance should be examined in crustacea where GABA is likely to act as a transmitter of post-synaptic inhibition[3].

Action potentials developed by the slowly adapting stretch receptor neurones of the Murray River crayfish *Eustacus armatus* were recorded following the method of Florey[4]. When 10–30 μg/ml. of GABA (1×10^{-4}–3×10^{-4} M) was applied to these cells an immediate inhibition of the spike discharge was consistently produced followed by a slow recovery beginning 30–60 s after the application. Bicuculline in concentrations ranging from 3–30 μg/ml. had the effect either of reducing or of completely preventing the inhibitory action of GABA. The blocking effect was fully developed in 5–10 min and could be wholly reversed by washing the preparation for the same length of time. When comparisons were made on the same preparations, bicuculline was about ten times more potent as a GABA antagonist, weight for weight, than was picrotoxin, and three times more effective than picrotoxinin. These ratios are in accord with other reported actions of the substances: the convulsant dose of bicuculline in rabbits is 0·2 mg/kg (ref. 5); those for picrotoxin and picrotoxinin in mice 2·0 and 1·0 mg/kg respectively[6]. The inhibition of neurones of Deiters's nucleus following cerebellar stimulation is prevented by 0·2 mg/kg of bicuculline[2] and by 10 mg/kg of picrotoxin[7].

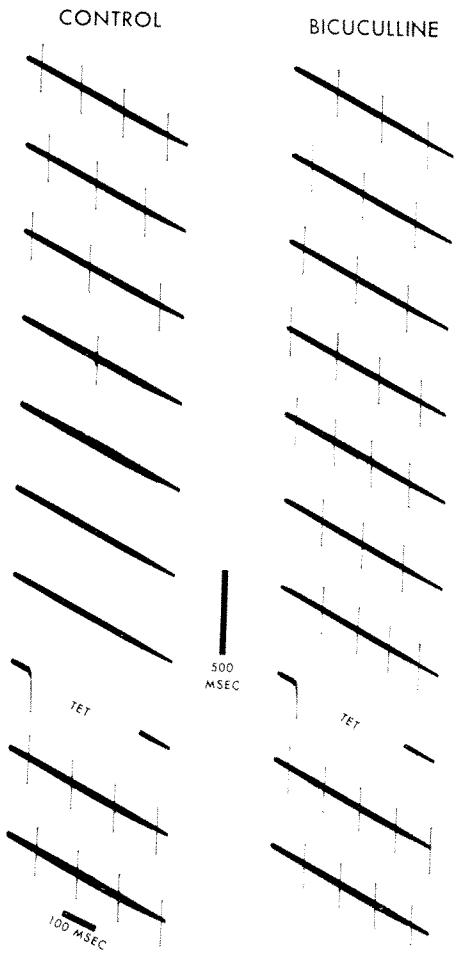

Fig. 1. The action of bicuculline (30 μg/ml.) on the inhibition of discharge of a crayfish stretch receptor neurone brought about by stimulation (TET) of its inhibitory nerve supply for 400 ms with 5 V, 0·1 ms pulses at 100/s. The traces in each column are continuous and read from below upwards; the 500 ms vertical bar indicates rate of film movement.

Bicuculline also antagonized the inhibition of discharge of the crayfish neurones which follows repetitive stimulation of their inhibitory nerve supply (Fig. 1); and again this substance was approximately 10 times more potent than picrotoxin. Because it is probable that this crustacean inhibitory mechanism is mediated through the release of GABA as a transmitter, it seems that in crustacea, as in the mammalian central nervous system, bicuculline is a powerful antagonist of the actions of GABA whether applied exogenously or released by some synaptic mecha-

nism; and that bicuculline is more potent as an antagonist than is picrotoxin.

Doubtful Value of Bicuculline as a Specific Antagonist of GABA

In view of the recent report that bicuculline[1–3] antagonizes the action of γ-aminobutyric acid (GABA) at various sites in the central nervous system[4] we have systematically tested this alkaloid, applied by microiontophoresis to neurones in the cerebral cortex of four cats under 'Dial' anaesthesia. Two samples of bicuculline were used: the first was obtained from Pierce Chemicals; it was prepared either as a 0·1 M solution in dioxane, or by dissolving at a concentration of 0·05–0·1 M in dilute HCl (final *p*H 3). The second sample (bicuculline hydrochloride) was kindly given to us by Dr R. Manske (University of Waterloo): this was prepared as in the experiments of Curtis *et al.*[4] at a concentration of 10 mM in 165 mM NaCl (*p*H 4). One barrel of the multi-barrelled glass micropipettes was filled with these solutions 2–3 days before the experiments. The 0·1 M solutions did not readily pass iontophoretic currents > 30–50 nA (see ref. 4), but very large currents (≫100 nA) could be passed through the 10 mM solutions for several tens of minutes.

The tests were performed as follows. A given unit was excited in a regular manner by 4–6 s applications of L-glutamate (20–60 nA) at intervals of some 5 s (Figs. 1 and 2). The glutamate-evoked responses were then depressed to a various extent by different amounts of GABA applied for 30–40 s; in most cases, a total block of responses was achieved by doses of GABA in the range 7–28 nA. Bicuculline was then administered by an outward current (electrode tip relatively positive),

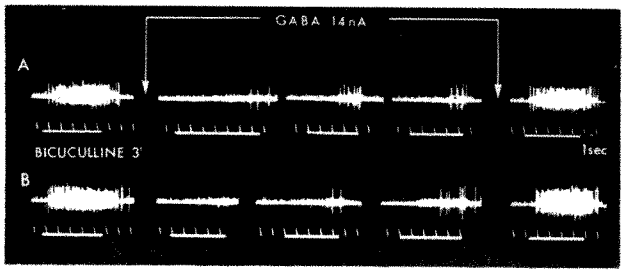

Fig. 1. Discharges of cortical neurone evoked by microiontophoretic release of L-glutamate (56 nA, during periods marked by white lines below oscilloscope trace); firing was almost completely blocked by release of GABA (14 nA: period between arrows) from another barrel of multiple micropipette. (*A*) Control; (*B*) 3 min after starting application of bicuculline (70 nA, from 0·05 M solution of hydrochloride).

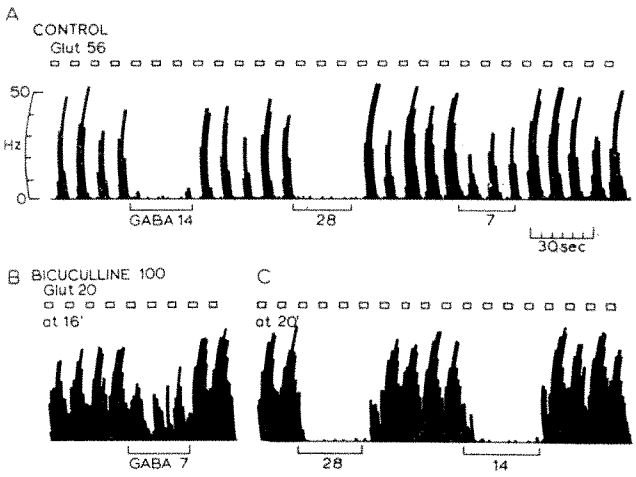

Fig. 2. Glutamate-evoked discharges of another cortical neurone, inhibited by three doses of GABA: paper trace records firing frequency. (*A*) Control period; (*B*) 16 min and (*C*) 20 min after starting release of bicuculline (100 nA, from 10 mM solution of hydrochloride in 165 mM NaCl). White squares indicate applications of L-glutamate; all doses are indicated in nA of iontophoretic current. Note sharply reduced doses of glutamate and spontaneous activity in *B* and *C*.

usually for periods of at least 5–10 min; during this time, GABA was reapplied to test again its depressant effects on the glutamate-evoked discharges. Whenever possible, dose–response curves for GABA were constructed (Fig. 3) by comparing the mean amplitude of three glutamate-evoked responses just before and during the release of GABA.

Of 32 units on which adequate tests could be made, 22 showed no clear change, six were more effectively depressed by GABA, and four somewhat less effectively, during the concurrent release of bicuculline. Very large doses of bicuculline (> 100 nA through 10 mM bicuculline-HCl in 165 mM NaCl) sometimes caused an increase in excitability, manifested by a gradual rise in "spontaneous" firing and greatly augmented responses to glutamate (Fig. 2). Not surprisingly, in these conditions GABA could not silence the cells so readily; but if the doses of glutamate were adjusted to yield a response at the control level, in all cases but one the effect produced by GABA was identical to that seen previously.

In Fig. 1, the oscilloscope traces show a very similar degree of inhibition produced by GABA during the initial control period (*A*) and 3 min after starting the release of bicuculline (*B*). In Fig. 2, paper traces recording the rate of firing of another cortical neurone show the glutamate-evoked discharge and its depression by three doses of GABA (*A*): the second set of traces demonstrates that even 20 min after the start of a large application of bicuculline (100 nA), there was no evidence of any diminished potency of GABA (*B*, *C*). Some GABA dose–response curves obtained from other neurones before and during the release of bicuculline are also illustrated (Fig. 3). Bicuculline was also tested four times on three acetylcholine-sensitive cells which were either firing rapidly "spontaneously" or were excited by regular applications of acetylcholine. The inhibition of these discharges by GABA was in no way diminished by bicuculline given for as long as 15 min.

Because of the failure to produce any clear effects, one might question whether the samples of bicuculline used had any biological activity. We tested aliquots of solutions taken from the micropipette, either by intravenous injection or by direct application to the cortical surface, and in this way confirmed the original observations[5] of pronounced convulsions following the systemic administration of bicuculline (5 μmole); further, we found that even weak solutions (1 mM) applied to the cortical surface rapidly evoke local paroxysmal activity. Clearly our

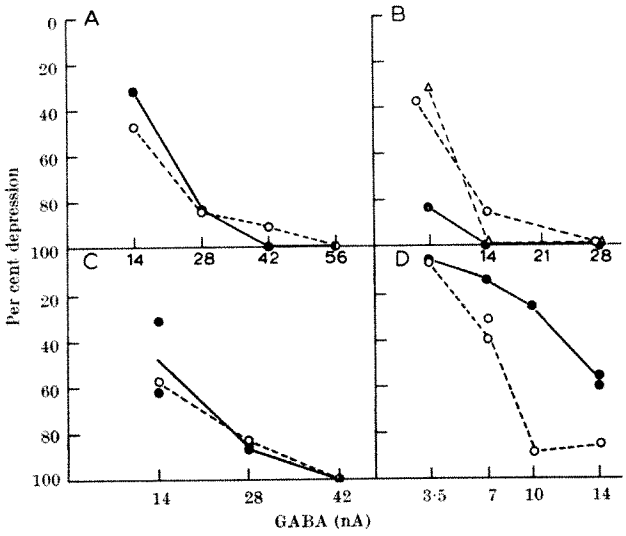

Fig. 3. Dose–response curves for GABA effect on glutamate-evoked firing of four other cortical neurones. ○—○, Control; ●—●, during iontophoretic release of bicuculline; △—△, control after. Doses of bicuculline and periods of release were respectively: (*A*) 25 nA, 6 min; (*B*) 25 nA, 6 min; (*C*) 50 nA, 14 min; (*D*) 70 nA, 20 min.

samples were not inactive, and bicuculline does have a convulsant action on the cerebral cortex. Paroxysmal activity of this type can, however, be elicited by a variety of procedures—such as local freezing, prolonged neural isolation, and the application of many substances, including strychnine and curare. There is no ground for thinking that these various procedures interfere specifically with the action of GABA. Whatever the mechanism of its convulsant action, we find it difficult to see how bicuculline could be useful for critical tests of GABA-mediated inhibition.

Bicuculline and Central GABA Receptors

We are unable to accept the implication by Krnjević and his associates[1] that we erred in reporting[2] bicuculline to be a relatively specific antagonist of γ-aminobutyric acid (GABA) in the central nervous system of the cat.

The bicuculline (Fluka, AG) used in our investigation was identified on the basis of the following observations: melting point, 201°–205° C; elemental analysis (calculated from formula $C_{20}H_{17}NO_6$: C, 65·39; H, 4·66; N, 3·81 per cent. Found: C, 65·38; H, 4·73; N, 3·83 per cent); homogeneity by thin layer chromatography on silica gel HF_{254} in three solvent systems, located with iodine (*n*-butanol–acetic acid–water, 4 : 1 : 1; chloroform–methanol, 1 : 1; cyclohexane–chloroform–33 per cent ethanolic dimethylamine, 5 : 4 : 1); mass, infrared and NMR spectra in accordance with the proposed structure and previous findings[3–5]. When prepared without heating, solutions of the alkaloid in 165 mM NaCl at *p*H 3–3·2 contained approximately 5 mM bicuculline.

Our report[2] indicated that this bicuculline blocked the depression by GABA of both spontaneous and amino-acid (DL-homocysteate) induced firing of cortical neurones in cats anaesthetized with pentobarbitone; consistent observations had been made on twenty-two pyramidal tract neurones in ten preparations. This action has been confirmed in animals anaesthetized with 'Dial'–urethane, and with neurones excited by L-glutamate, as shown in Fig. 1. Enhancement of neuronal firing by bicuculline was not responsible for an apparent loss of GABA sensitivity, for rates of firing could be restored to pre-bicuculline levels by reducing the amount of amino-acid excitant ejected, and a control was provided by using another depressant such as glycine. In addition to the antagonism demonstrated between bicuculline and GABA in the cerebellum, cerebral cortex, and spinal cord[2], we have also found that this substance consistently blocks the inhibitory effect of both GABA and impulses in Purkinje cell axons on neurones of Deiters's nucleus[6], and is an antagonist of both the action of GABA on, and inhibition

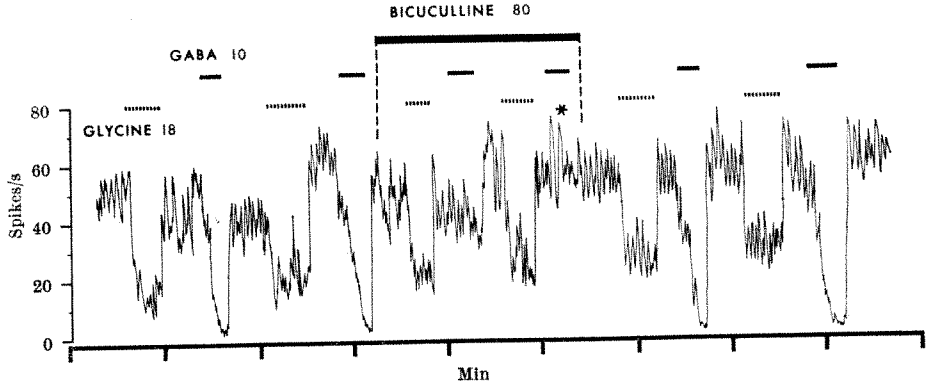

Fig. 1. Effect of bicuculline on the inhibition by glycine and GABA of an antidromically identified deep pyramidal cell in the postcruciate cerebral cortex. Cat anaesthetized with 'Dial'–urethane, rate of cell firing (ordinate) maintained by the continuous electrophoretic ejection of L-glutamate (12 nA) from one barrel of a seven barrel micropipette. Glycine (18 nA) and GABA (10 nA) were ejected at regular intervals for the periods indicated by the dotted and solid horizontal lines respectively. Bicuculline, ejected from a barrel containing 5 mM bicuculline hydrochloride in 165 mM NaCl with a current of 80 nA over the time indicated by the thick horizontal bar and vertical broken lines, rapidly and reversibly suppressed the effect of GABA (abolition of GABA action indicated by an asterisk) without reducing that of glycine. Abscissa, time (min).

of, neurones in the ventrobasal thalamus[7] and hippocampus[8]. Furthermore, bicuculline blocks the effect of GABA on stretch receptor neurones of the crayfish *Eustacus armatus*, and the synaptic inhibition of these neurones[9].

Identical pharmacological results in the feline central nervous system have been obtained with other samples of bicuculline, including that purchased from the Pierce Chemical Company, K and K Laboratories, and one kindly provided by Dr R. H. F. Manske.

We are therefore convinced that our results do indeed relate to bicuculline and that our findings provide significant evidence for the function of GABA as the transmitter released at certain inhibitory synapses in the feline cerebral cortex, cerebellum, brain stem, thalamus and hippocampus.

Because bicuculline is also an antagonist of the depressant action of imidazole acetic acid, further neurochemical evidence is required to determine whether this compound also has a role as a transmitter at bicuculline-sensitive inhibitory synapses.

We thank Mr P. M. Beart for assistance.

Temporal Characteristics of Amnesia induced by Protein Synthesis Inhibitor: Determination by Shock Level

It is widely accepted that cerebral protein synthesis is involved in "long term" but not "short term" memory. Evidence for this comes from experiments in which amnesia for a multiple-trial avoidance task is induced by administration of protein synthesis inhibitors before or shortly after training[1–3]. In mice[4–6], the amnesia, which is permanent, does not appear until 3 h or more after training, leading to the notion of a "short term" memory, and is not produced if the criterion for learning is too severe. We have given mice a different learning task and used the protein synthesis inhibitor cycloheximide to induce amnesia that has such different characteristics as to warrant a re-evaluation of the hypothesis.

Subjects were male mice weighing 25 g from the C57Bl/6J strain. Apparatus was a standard passive avoidance box with a small clear 'Plexiglas' compartment separated from a large darkened compartment by a guillotine door. The large compartment was illuminated by a flashing light which came on when the door was opened. After the mice had entered the large compartment, a single 2 s foot shock (either 0·16 or 1·6 mA) was automatically given. Latencies to enter the large compartment were recorded on the training trial and on the retention test trial.

Mice were injected subcutaneously with 3 mg of cycloheximide dissolved in 0·3 ml. 0·85 per cent saline or with saline alone. At this dose level less than 10 per cent were sick at retention test time. These were discarded. For determination of the extent of inhibition of cerebral protein synthesis mice were injected intraperitoneally at various times after receiving the drug with 25 μCi of L-4,5-^{3}H-leucine. Exactly 30 min later, mice were decapitated and brains removed for determination of amino-acid incorporation by a method similar to that of Barondes and Cohen[7] and to be described elsewhere (Randt, C. T., Barnett, C. T., B. S. M., and D. Q., in preparation). Fig. 1 shows that maximum inhibition of amino-acid incorporation was attained at around 30 min after cycloheximide injection and that the inhibition disappeared over the subsequent 6 h. Two measures of incorporation are presented: specific activity of the protein (c.p.m./mg) and the ratio of total incorporated radioactivity to TCA-soluble radioactivity, which is presumably free amino-acid.

In our first experiment we injected groups of mice with cycloheximide at various times both before and after the one-trial learning task. Half the subjects were trained with high (1·6 mA) foot shock and half with low (0·16 mA) foot shock. Half of these groups were tested for retention 6 h after training and the other half 24 h after. Animals tested 6 h after training were divided into five groups ($n = 40$) and injected with cycloheximide at the

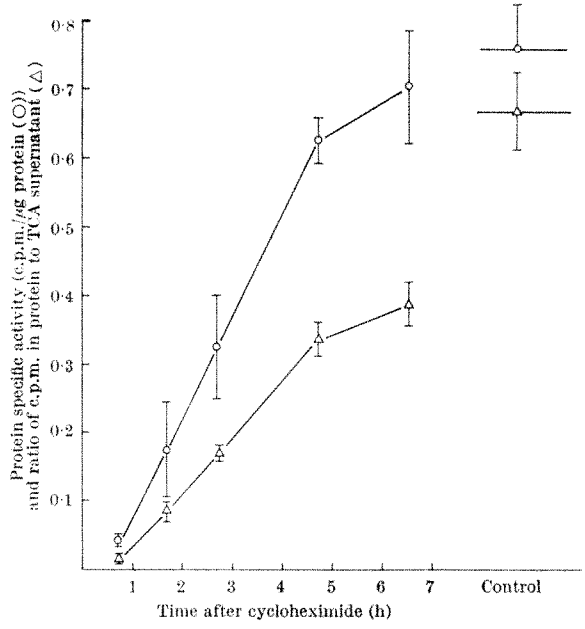

Fig. 1. Incorporation of intraperitoneally injected ^{3}H-leucine into total brain protein during a 30 min period as a function of time after subcutaneous administration of 3 mg cycloheximide.

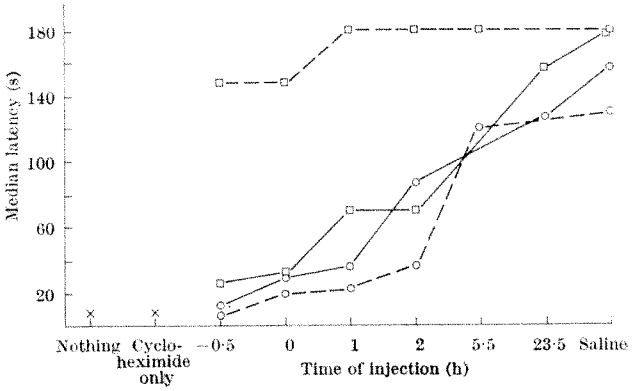

Fig. 2. Median latency to enter the large compartment on the retention test trial as a function of time interval between cycloheximide injection and training. □—□, High shock, test 24 h; ○—○, low shock, test 24 h; □ - - - □, high shock, test 6 h; ○ - - - ○, low shock, test 6 h.

following times: 30 min before training, immediately after, 1, 2, and 5·5 h after training. A sixth group ($n = 40$) was injected with saline. Half of each group ($n = 20$) was trained with high and the other half with low foot shock. The same injection times were used for mice tested 24 h after training, except that a group injected 23·5 h after training replaced the 5·5 h group. Again, half of each group was trained with high and the other half with low shock. Two further groups were trained: one group ($n = 20$) was injected with cycloheximide but not given foot shock, and a second group ($n = 20$) received neither foot shock nor cycloheximide.

Results are shown in Fig. 2. When memory is tested 24 h after learning, both the high and the low foot shock groups show a similar temporal gradient of amnesia, retention being poorest when cycloheximide is injected before and immediately after learning. When each of these groups is compared statistically with the appropriate saline control group (using Mann–Whitney U tests), significant amnesia occurs with injection delays as long as 1 h after training ($P < 0.05$) for both high and low foot shock groups. By contrast, there are marked differences between the two shock intensities when retention is tested 6 h after training. The low foot shock groups show a temporal gradient closely comparable with that seen in the groups tested at 24 h. In these conditions, amnesia can be produced when cycloheximide is injected as long as 2 h after training ($P < 0.05$). There is, however, no loss of memory evident in any of the high shock groups. Apparently, amnesia for the high shock takes some time to develop; it is present 24 h but not 6 h after training.

With low shock, amnesia is present 6 h after training, but memory may have been present at some earlier time as predicted by the two-stage hypothesis[2,3]. Habits learned under different shock levels may go into long-term storage at different rates. To investigate this we carried out a second experiment, in which we tested for retention of habits that had been in storage for different times. Five training-test intervals were chosen: 1 min, 5 min, 6 h, 24 h, and 48 h. Four groups ($n = 20$) were assigned to each interval; two of these groups were injected with saline and trained with either high or low shock, and two were injected with cycloheximide and trained with either high or low shock.

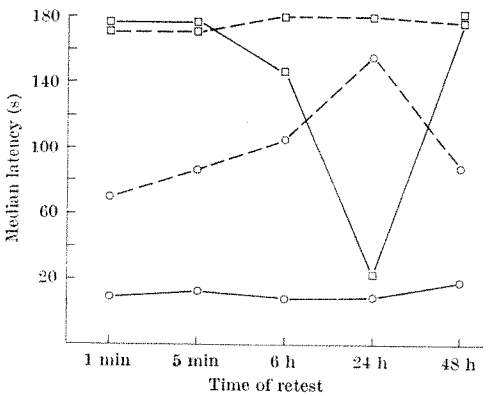

Fig. 3. Median latency to enter the large compartment on the test trial as a function of time between the training trial and the retention test. Cycloheximide and saline were injected 30 min before training for all groups. □, High shock; ○, low shock; - - - saline; ———, cycloheximide.

The results are shown in Fig. 3. The low-shock, saline-injected subjects show an improvement in retention with time. Comparison of these groups with the cycloheximide injected groups indicates that significant memory loss occurs at all intervals ($P < 0.001$ for 1 min, 5 min, 6 h, 24 h; $P < 0.01$ for 48 h), and no time can be found when memory is present. With the high shock condition, on the other hand, there is no significant difference in latencies between saline and cycloheximide-injected subjects until 24 h after testing ($P < 0.001$). At 48 h, however, the memory returns spontaneously. It therefore seems that the amnesia apparent at 24 h after training with high shock is temporary.

Two specific conclusions seem warranted by these data. First, the presence of a protein synthesis-resistant "short-term" memory is clearly dependent on whether the habit was learned under high or low shock. The amnesia for the high shock takes time to develop but amnesia for the low shock is apparent when retention is tested 1 min after training. This suggests that in certain conditions cycloheximide may prevent the retention of "short term" memories. It is improbable that this is simply the result of failure to learn. The reaction to the foot shock by the cycloheximide-injected mice was indistinguishable from the saline controls; furthermore, we have shown that the amnesia for the low foot shock is not permanent but can be recovered by giving the mice a "reminder shock"[8]. This could not occur if the mice had not learned the response. Second, the permanence of the amnesia is also dependent on the level of foot shock used to punish the response. The memory for the high shock returns spontaneously 48 h after training, but memory for the low shock did not return within the time intervals we studied.

These findings raise the possibility that protein synthesis inhibitors may be interfering with mechanisms necessary for information retrieval rather than exclusively preventing consolidation of long-term memory.

Extremely Small Motions of the Basilar Membrane in the Inner Ear

THERE is a great deal of speculation about the amplitudes of cochlear membrane motion calculated by various authors for the lower threshold of hearing, which indicate an order of magnitude of motion smaller than the diameter of a hydrogen atom. These deflexions are detected and converted by the hair cells into nerve impulses which are recognized by the brain. Because these motions are too small to be observed physically, the various published values are theoretical extensions of experiments performed at much higher amplitudes. For example, von Békésy[1,2] has linearly extrapolated his measurements to give 10^{-11} cm r.m.s. basilar membrane motion for 1,000 Hz at the lower threshold. Because the behaviour of the auditory system is nonlinear, the calculations based on a linear model are questionable.

In order to appreciate the magnitude of these excursions one should consider that the amplitude of corresponding air particle motion in the sound pressure waves, just barely audible to the ear, is of the order of 10^{-9} cm at 1,000 Hz. The thermal fluctuations of air particles at room temperature and pressure are of the order of 10^{-10} cm, that is, the signal to noise ratio is 10.

The model used in our investigation to calculate the motion of the basilar membrane at low intensities is based on the anatomical descriptions of von Békésy[1] and Iurato[3]. These authors describe the basilar membrane as a long, narrow tissue membrane with no initial tension. Bending stresses in such a membrane with thickness h dominate all other stresses when the deflexions of the membrane are small compared with h. Axial tension was not observed experimentally in the long and narrow basilar membrane, so the idealized model chosen is that of a series of independent tissue beams which are transverse to the longitudinal axis of the unrolled cochlea. A clear picture of the model may be obtained by cutting transverse slits in the basilar membrane and then treating each strip as a beam fixed at both ends. Thus the small deflexions of the basilar membrane may be described by the bending theory of beams. Von Békésy's hydrostatic measurements of cochlear duct flexibility are used to compute a Young's modulus of near 10^7 dynes/cm^2 for the membrane tissue which is in the same range as Young's modulus for other tissues such as muscle.

When the membrane deflexions are of the same order of magnitude as h, a nonlinear term must be added to the beam equation due to the stretching of the middle plane of the beam. This added term is very similar to the nonlinear resistance term of a string with no initial tension. Such a term becomes important in the upper hearing range where the observed displacements are of the same order as h. Because of this nonlinearity, the model chosen thus predicts saturation and presence of overtones at high intensity levels which is in accord with observed auditory behaviour.

On the basis of the model described, the calculated values of the motion of the basilar membrane are between one and two orders of magnitude larger than those based on von Békésy's linear model. At 3,000 Hz von Békésy's calculated basilar membrane motion is 8×10^{-11} cm r.m.s. at the lower threshold, but our model predicts a value of 2×10^{-9} cm r.m.s. at that frequency. Rhode and Geisler[4] have measured basilar membrane motion in the mid amplitude range of the squirrel monkey cochlea using the Mössbauer effect. Linear extrapolation of their data to the lower threshold gives about 5×10^{-10} to 10^{-9} cm at 5,000 Hz. The calculated values for our model are in agreement. Although these recent calculations are larger than the ones von Békésy predicted, they are still on a subatomic scale at the lower hearing threshold.

Harris[5] has computed the Brownian motion of the basilar membrane based on both a weakly coupled and a strongly coupled model of the cochlear hair cells. According to Spoendlin[6] the hair cells are tightly fixed in the reticular membrane, resulting in strong coupling between adjacent hair cells. For the strongly coupled model at 3,000 Hz the thermal fluctuations have an amplitude of $4{\cdot}8 \times 10^{-11}$ cm r.m.s. or $6{\cdot}8 \times 10^{-11}$ cm peak value. Using the above value as a measure of the noise level, von Békésy's calculated basilar membrane motion gives a signal to noise ratio just above unity while calculations from our model give a signal to noise ratio an order of magnitude higher. The latter value seems to be more reasonable.

Demonstration of Intention in the Reaching Behaviour of Neonate Humans

Neonate infants extend their hands towards seen objects, touch, and occasionally grasp them[1] (see Fig. 1). To some observers this behaviour looks like true reaching, but others[2,3] dismiss it as excited threshing. It will therefore be useful to define reaching according to two characteristics: that it is oriented, and that it expresses a distal aim or intention.

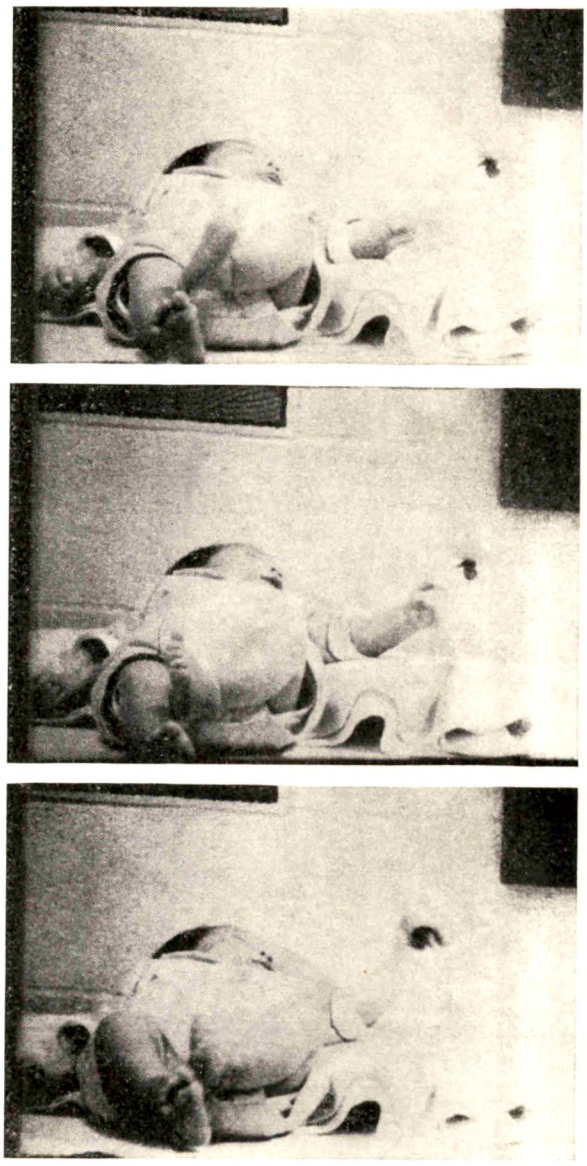

Fig. 1. A sample of neonate reaching taken from a film of a 10-day-old infant, in position for experiment 1. Top, 0 ms; middle, 324 ms; bottom, 756 ms.

The degree of orientation in the behaviour was assessed by presenting the infants with an object in one of five positions: midline 30° right, 60° right, 30° left and 60° left. Five alert infants served as subjects, usually having just been fed, each being observed—and filmed—for each position, each starting with a different position and proceeding through in counterbalanced order. The object was presented for 3 min continuously and there was a one-day interval between each presentation. The ages of the infants (which had been delivered without medica-

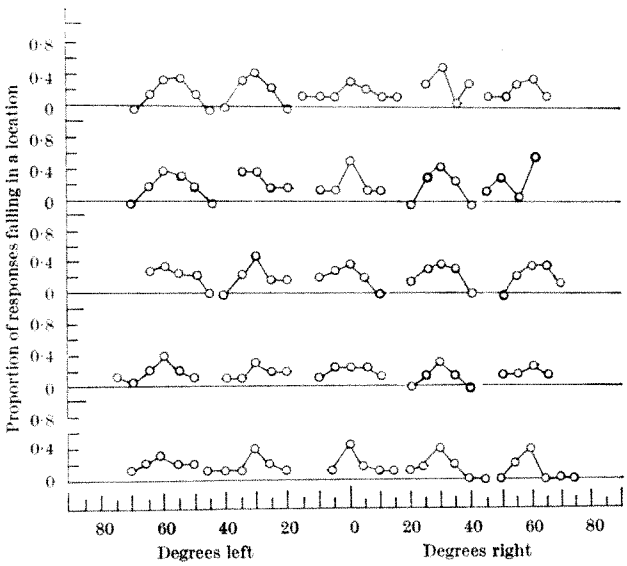

Fig. 2. The results of experiment 1. Each row represents the results for a single infant.

tion) at the beginning of the experiment were 6, 8, 9, 10 and 11 days. The object was an orange foam rubber sphere, 3·5 cm in diameter, placed 19 cm from the infant; the infant, loosely held in position by an arrangement of pillows (Fig. 1), lay under the object.

The films were analysed by two observers who recorded the location of the infant's hands on a protractor centred on the infant's midline and placed in the film plane, at the zenith of each arm extension. Seventy per cent of hand positions for each object position were within 5°—1·5 cm—of the object (Fig. 2). The behaviour was therefore considered oriented.

The assessment of intention was more complicated. We used a virtual object presentation (Fig. 3), which depends on the fact that neonate humans have stereoscopic vision[4–7]. Such objects look like real objects and so should elicit the same amount of reaching or excited threshing. If, however, the infant intends to contact the seen object when he extends his hand towards it, the virtual object will frustrate him, whereas frustration

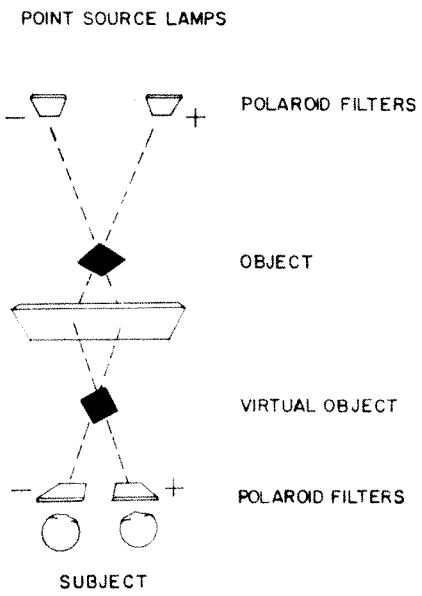

Fig. 3. A schematic diagram of a device to produce virtual objects.

should not result if the hand and arm behaviour is mere threshing, when there would be no intention to be violated. In this case one would also expect to see a lower rate of behaviour in the virtual object situation, for there can be no tactile input to stimulate further response. As measures of frustration, we used distressed crying and time before crying became chronic, compared with the same measures taken during real object presentations.

The infant was placed conjugate with the lamps 40 cm from the screen. Seven male and four female infants, whose ages were 8, 8, 10, 11, 12, 17, 18, 21, 24, 28 and 31 days at testing, served as subjects. They were full term and born without anaesthesia. Only infants whose preferred "reaching" posture allowed them to view the screen comfortably, and who were not upset by the goggles, could be used, so the first session was taken up with discovering the preferred posture and fitting the goggles. At the second session the infants were presented with one of the three virtual objects: a red transparent plastic tetrahedron, a red transparent plastic hexahedron, or a blue transparent plastic sphere, which dangled in the light beams. Initially it was placed against the screen on the opposite side from the baby, so that the virtual object was 40 cm away from him. After 1 min it was brought in slowly until reaching began. The average distance at which reaching began was 20 cm. The object was left as long as reaching persisted, or until the baby's crying was well established and upsetting to mother and experimenters, at which point the baby was soothed and then replaced in the apparatus. A virtual object was presented at 40 cm for as long as the infant had been in the situation before, and reaching behaviour was filmed. Other aspects of behaviour were recorded by an observer. A comparison group of forty infants in the same age range was run in a similar setup with real objects. These infants could assume any posture, were not wearing goggles and were reaching for palpable objects which provided tactile input on contact.

The results were that all the virtual-object infants cried, with a latency after the first reach of 15–75 s. None of the infants in the real object situation cried: the range of duration of presentation used with them without upset was 6–12 min. By the measures adopted here, therefore, the virtual object produced much more frustration. The differences between the real and virtual object groups could reflect the fact that the virtual object group was wearing goggles; but the group was preselected for its ability to wear goggles without crying for 3 min, much longer than any of them managed in the experiment; and in the post test, only two of the eleven infants cried, that crying not being associated with reaching. It therefore seems that it was not the situation which produced the frustration, but the consequences of attempting to reach for the virtual object. No crying at all occurred during the pretest, or during the first minute of the experiment, until the virtual object had been brought in to 20 cm and attempts to reach it had begun. During the post test, no reaching occurred and only two babies out of eleven cried. So the observed behaviour seems to have been a consequence of frustration produced by the experimental situation, and demonstrates "intention" in the observed behaviour.

Maternal Thyroid Disease and Twinning

INTERRELATIONSHIPS suggested by various workers among thyroid function, twinning and chromosomal abnormalities[1-4] have prompted this study of thyroid disease in mothers of twins.

All Caucasian women who had delivered twins weighing 500 g or more were ascertained from the obstetrical files of the New York–Cornell Medical Center for the period 1955–64. There were 409 mothers of twins; using the same files, each was matched as closely as possible in age, race, colour, hospital service and delivery date, to a mother who had only singleton pregnancies. All information was obtained directly from the hospital medical record of each study mother.

Thyroid pathology was established on the basis of laboratory or pathology findings, thyroidectomy with final diagnosis, or repeated clinical description of thyroid "goitre" or "tumour" in nonpregnant women. Eight mothers of twins and two mothers of singletons with histories of taking thyroid pills have not been included in the pathological group, because it cannot be assumed that this information constitutes direct evidence of thyroid disease in all instances. Only data for maternal thyroid disease preceding the study pregnancies were included in this analysis. The data were analysed by the matched-pair method[5].

Table 1. THYROID DISEASE IN MOTHERS OF TWINS AND IN MOTHERS OF SINGLETONS

		Thyroid disease history Mothers of twins		
		Positive	Negative	Total
Mothers of singletons	Positive	0	4	4
	Negative	13	392	405
	Total	13	396	409

$t = 2{\cdot}18$, $P < 0{\cdot}05$.

The results appear in Table 1. There were thirteen pairings where the mother of twins had a positive history of thyroid disease and the respective mothers of singletons did not, and only four pairings in which the situation was reversed. The excess of mothers of twins with thyroid disease is statistically significant, $P < 0{\cdot}05$; using the exact method[6], $P = 0{\cdot}049$. Because the influences of age and race were controlled in these pairings, the heterogeneity in thyroid disease observed must be caused by other biological differences between mothers of twins and mothers of singletons. The data could not be analysed in relation to monozygous and dizygous twinning, because it is impossible accurately to determine the zygosity on all like-sexed twin pairs at birth.

An increased frequency of thyroid disease[1,7] and/or thyroid autoantibodies[2,8] has been found in mothers of patients with chromosomal aberrations, that is, Down's and Turner's syndromes. Understandably, thyroid disease and antibodies were determined in the latter mothers a considerable time after the pregnancy in question. That thyroid dysfunction may exist before such pregnancies is suggested by the result of this investigation and the relationships observed in the following studies.

The twinning rate is high among women who have had offspring with Turner's syndrome[9]. Although data are not available on a complete twin sample throughout development, reports suggest that this syndrome and other forms of aberrant sex development with abnormal karyotypes may not be unusual in twins[10-14]. Other lines of evidence indicate not only that mothers of twins had more offspring with abnormal genital development (F. V. D. G., unpublished), but also that gynaecological disease is associated with twinning[15]. It is therefore interesting that twin born individuals and their siblings seem often to have children whose development is defective, whether or not they have abnormal chromosomal complements[11,14,16,17].

Elimination of the "*p*H Effect" in Cell Fragility Determinations

WHEN fish is stored frozen, the properties of the flesh slowly change so that the thawed material becomes tougher, with consequent problems for the food industry. Research in the field has been hindered by the lack of convenient methods for measuring the phenomenon. Love and Mackay[1,2] devised a simple technique in which 200 mg of muscle is subjected to a standard gentle homogenization in 20 ml. dilute formaldehyde (the "cell fragility" technique). Fresh fish is disintegrated to the myofibrillar level, but after freezing and thawing increasingly less disintegration occurs as the cold-storage period is increased; after about 12 weeks at −14° C, only intact cells are present. The extent of disintegration is assessed from the light-scattering characteristics of the homogenate, which are measured in a colorimeter. The soft tissue of fresh fish forms an opaque "soup" of high absorbance, whereas tissue which has toughened is shredded to a few strands, most of the suspending medium remaining clear and giving a low reading in the colorimeter. It was later discovered, however, that the readings were influenced by the *p*H of the muscle[3,4] in such a way that toughening attributable to low *p*H, without cold storage, gives rise to a high absorbance, whereas toughening in the frozen state gave a low absorbance reading.

This method was therefore useless for quality control of frozen fish unless the *p*H could be determined also. The routine determination of *p*H along with cell fragility has been suggested[5], but this would make quality control more tedious without guaranteeing accurate assessment of storage history. Though an experienced operator can distinguish by eye between homogenates of high *p*H–low absorbance density and cold storage–low absorbance, this requires skill and leaves room for doubt about values obtained in different laboratories.

By soaking pieces of muscle in weak buffers of varying *p*H we have shown that the effect lies in the *p*H itself, and not necessarily in the protein depletion that often characterizes fish of high post-mortem *p*H. A sample of fresh muscle can be made to yield almost any desired cell fragility value by a 4-day soaking in the appropriate buffer. Phase-contrast microscopy of "pale" homogenates from high *p*H fish showed a lack of definition compared with those of low *p*H fish, as though the formaldehyde in the suspending liquid has been insufficient to precipitate the cell proteins and partial dissolution was resulting in a more transparent suspension. Likewise, electron photomicrographs of homogenates revealed the presence of more ill-defined debris outside the myofibrils in the high *p*H specimens, as though protein had left the cell during homogenization. We have now tried stronger precipitants to counteract the dispersion of the proteins, and have found the most satisfactory combination to be 2 per cent trichloroacetic acid in 1·2 per cent formaldehyde. The absorbance after using such a medium is often above the sensitive range of the colorimeter, so we have reduced the sample size to 100 mg.

To assess this modified technique we dissected several anterior myotomes from each of forty cod (*Gadus morrhua* L.) which were in rigor mortis, freed them from connective tissue, and wrapped them separately in aluminium foil. Those from each individual fish were placed together in a numbered bottle, frozen at −30° C and stored at −14° C. A sample was thawed every 2 weeks and determined by both the original and the modified methods. The average *p*H of twenty of the cod was 7·02 (range 6·96–7·17) and that of the other twenty was 6·29 (6·06–6·39).

The superiority of the modified method is clear from Fig. 1. The range of *p*H is about as large as it is possible to obtain with this species; the ultimate values are lower because of the smaller size of the sample. Over a batch of 384 cod taken from various grounds it was found that the correlation coefficient between *p*H and cell fragility (original method) was −0·666 ($P < 0·01$) whereas with the modified method it was only +0·125 ($P < 0·05$). Readings from the modified method were also less scattered. They showed less effect of water content and length of fish, and were better correlated with the results of tasting tests for toughness and "cold storage flavour".

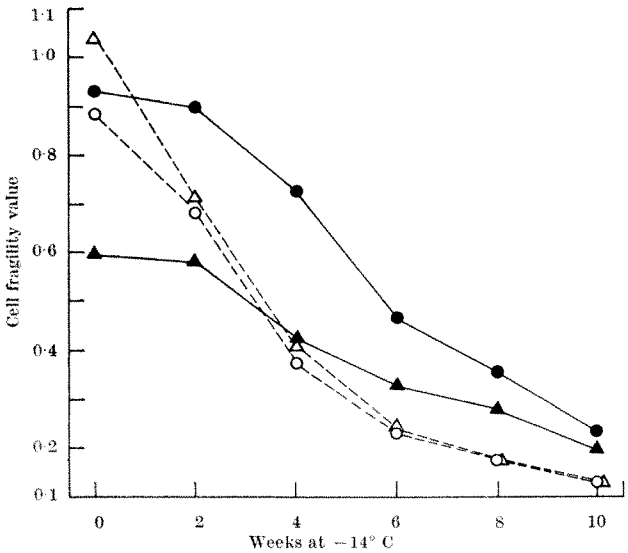

Fig. 1. Cell fragility values of cod muscle of high and low *p*H during storage at −14° C, as determined by the original and modified methods. The *p*H modifies the values of the original method but has almost no effect on those of the modified method. Original method: ▲, high and, ●, low *p*H; modified method: △, high and, ○, low *p*H.

A full account of this work will be published elsewhere.

We thank Mr P. F. Howgate for the taste panel assessment and computer programming. This work was part of the programme of the Ministry of Technology.

Nature of Acquired Resistance to Filarial Infection in Albino Rats

Albino rats infected with the filarial parasite *Litomosoides carinii* acquire resistance in 3–4 months as judged by the absence of microfilariae in the peripheral blood[1]. The rats at this stage have latent infection revealed by the presence of adult worms and microfilariae in the pleural cavity. *In vivo* studies on the factors involved suggested that circulating antibodies of these rats which include a homologous anaphylactic[2] and reaginic[3] types do not play a significant part[4]. Available data, however, indicated that the acquired resistance was related to a systemic cell-mediated immunity[3] that seems to be most active in the pleural cavity[4], where the adult worms and microfilariae were present. We report here the results of a study of the acquired resistance.

Infection was induced and monitored as described elsewhere[2,4]. Circulating antibodies of the rats with latent infection and the hyperimmune sera induced in rabbits against whole adult *L. carinii* did not affect the microfilariae or adult worms *in vitro*. Further, respiratory quotient of the adult worms (0·91) as measured by the Warburg apparatus[5] in Krebs–Ringer glucose medium was found unaffected in the presence of the antisera. Cortisone and radiation have been known to modify immune response[6], so the effect of such treatment has been studied in rats with latent infection. Cortisone was administered subcutaneously to five rats with latent infection at a dose of 50 mg/kg daily for 13 days. This resulted in microfilaraemia in the rats 4–7 days after the initiation of the treatment suggesting suppression of acquired immunity by the hormone. A similar effect was observed when five rats with latent infection were subjected to irradiation at a dose of about 800 rad from a ^{60}Co source. Further radiation treatment of ten infected rats or transplantation of about fifteen female worms into the thoracic cavity[4] of irradiated uninfected rats led to prolongation of the time required for the development of acquired immunity by 1–4 months.

To see whether adult worms or microfilariae were responsible for inducing the resistance, further experiments were conducted. In four groups of rats, each group containing five animals, one of the following types of worms was transplanted into the thoracic cavity: large

numbers of adult worms of both sexes; females alone; males alone; and worms killed with solid CO_2 immediately before transplant. When the infection in animals of the first two groups became latent as shown by the absence of microfilaraemia, each animal in the four groups was challenged with fresh female worms. In these conditions microfilaraemia was observed only in groups originally transplanted with live males and dead worms. The results therefore suggest development of acquired resistance to the infection arising from live adult female worms or microfilariae but not because of adult males. In a subsequent experiment it was found that female worms, exhausted of microfilariae by serial passages in rats till they no longer caused microfilaraemia, failed to induce acquired resistance, thus implicating microfilariae as the immunizing agent. Indeed, repeated injections of microfilariae, collected from the thoracic cavity of infected rats, into normal rats resulted in development of acquired resistance confirming these conclusions.

There are two possible reasons for the absence of microfilariae in the peripheral blood of rats with latent infection. The microfilariae may enter the blood from the thoracic cavity but be trapped in immune sites such as lymph nodes, spleen, lungs or bone marrow. Such evidence as could be collected did not, however, support this hypothesis: for example, splenectomy or partial pneumonectomy did not result in microfilaraemia in rats with latent infection. There was no histological evidence for the presence of microfilariae in bone marrow, lymph glands, spleen, liver or lungs of these rats. Further, transplantation of adult worms in splenectomized normal rats led to development of acquired resistance in these rats as in the controls. Similarly, splenectomized infected rats developed latent infection in the usual way.

The other possibility was that the microfilariae were prevented from penetrating the capillaries of the pleura of these rats because of cellular reactions. When the thoracic contents of the rats, taken soon after the disappearance of microfilariae in the peripheral blood, were examined under a cover slip, a number of living microfilariae were seen attached to cells. Examination of the fluid after staining with Giemsa revealed intense cellular infiltration which consisted of lymphocytes, macrophages, eosinophils and giant cells. Most of the microfilariae were found to adhere to the lymphocytes and macrophages and occasionally to eosinophils in the thorax. The cells were firmly attached to the sheath or body of microfilariae, thereby immobilizing them (Fig. 1) which might eventually have led to their destruction (Fig. 2).

Recently, antilymphocyte serum (ALS) has been reported[7] to be an effective suppressor of cell-mediated immunity. Rabbit ALS to rat thymus cells was prepared according to the method of Gray *et al.*[8]. The serum did free the microfilariae from the attached cells when tested *in vitro* and, further, two injections with 1 ml. of ALS on alternate days into the thoracic cavity of three rats with latent infection resulted in appearance of microfilariae in the peripheral blood. Similar suppression of immune response by ALS has been recently reported by Kassai *et al.*[9] in *Nippostrongylus* and Domingo and Warren[10] in *Schistosoma mansoni* infections.

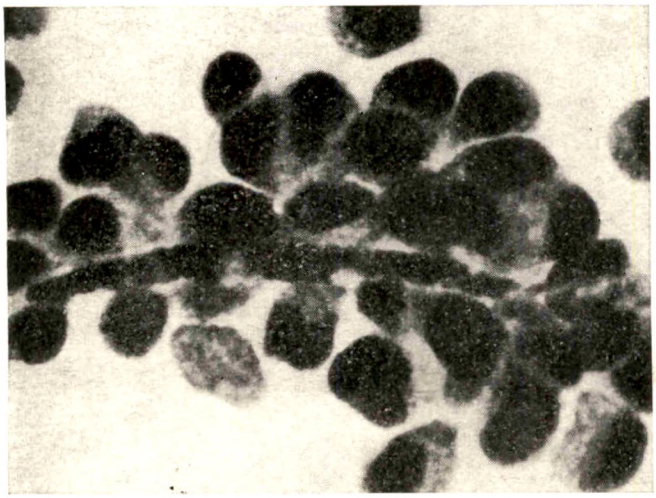

Fig. 1. Thoracic contents of a rat with latent infection, stained with Giemsa and showing adherence of microfilaria to lymphocytes and macrophages (×1,100).

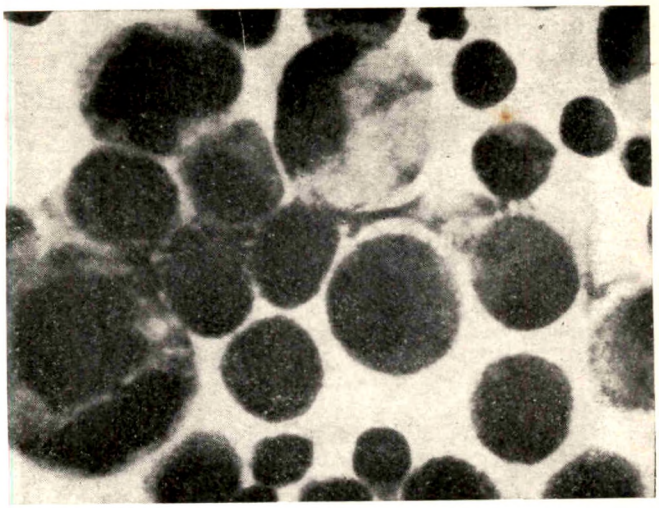

Fig. 2. Eventual destruction of microfilaria in rat thorax (×1,100).

Cell-mediated immunity has been recognized, in recent years, to be important in certain helminthic infections[11,12]. Our findings suggest that cell-mediated immunity possibly of the delayed hypersensitivity type is operative in albino rats with filarial infection. The ability of cortisone in inducing microfilaraemia in filarial patients[13] exhibiting no microfilariae in the peripheral blood prompts speculation that a similar type of cellular response, perhaps in lymphatics, exists in human infections.

This study was financed in part by a grant from the Indian Council of Medical Research. We thank Professor Robert Cruickshank for helpful discussions, and Drs S. Sriramachari and V. N. Damodaran for histological examinations.

Mode of Action of the Anthelminthic Thiabendazole in *Haemonchus contortus*

THIABENDAZOLE, 2,4′-thiazolyl benzimidazole, is an efficient, non-toxic, broad spectrum anthelminthic[1] and antifungal agent[2]. Its mode of action is not known, although its properties as a chelating agent have been noted[3].

A fumarate reductase (NADH : fumarate oxidoreductase) has been shown to be an essential component of the fermentative pathways of the adult parasitic stages of the nematode *Ascaris lumbricoides*[4], the cestodes *Moniezia expansa*[5] and *Hymenolepis diminuta*[6], and the trematode *Fasciola hepatica*[7]. Many parasitic helminths, living in environments low in oxygen, excrete succinic and volatile fatty acids. It is therefore probable that the fumarate reductase mechanism is essential for the regeneration of NAD in these parasites. This is in marked contrast to the aerobic metabolism of the hosts. There is also considerable evidence[6,8–10] that ATP is generated anaerobically in the oxidation of NADH by fumarate in these organisms.

The specific activities of, and the effect of thiabendazole on, the NADH oxidase and fumarate reductase of a particulate preparation from adult *Haemonchus contortus* were determined. Worm-free Merino lambs, aged 3 months, were infected with 6,000 *H. contortus* third-stage larvae. The lambs were slaughtered 4–6 weeks after infection, the abomasum removed and adult *H. contortus* recovered. The worms were cleaned with several washes of warm physiological saline, and homogenized immediately in 0·25 M sucrose–0·005 M Tris–HCl buffer (*p*H 7·5) at 0°–4° C. The homogenate was spun at 4° C for 10 min at 700*g* and the supernatant recentrifuged for 15 min at 7,000*g*. The residue was suspended in the sucrose solution and centrifuged at 17,000*g* for 15 min. The residue (particulate fraction) was resuspended in sucrose solution and used for enzyme assays on the same day. Generally 1–2 g of worms were recovered which yielded approximately 2·5 mg protein in the particulate fraction.

The rate of NADH oxidation by endogenous oxygen (NADH : O_2 oxidoreductase) was determined with a Shimadzu recording spectrophotometer at 340 nm (Table 1). Fumarate was found to stimulate markedly the rate of NADH oxidation, even under air ($P < 0.01$).

Table 1. EFFECT OF FUMARATE AND THIABENDAZOLE ON NADH OXIDATION MEASURED AEROBICALLY

Addition	Rate of NADH oxidation nmole/min/mg protein	Percentage of NADH oxidase activity	Percentage of NADH oxidase and fumarate reductase activities
NADH	80·0 (14)	100	64·8
NADH, fumarate	123·4 (14)	154·3	100
NADH, fumarate, 10^{-5} M thiabendazole	88·7 (4)	110·9	71·9
NADH, fumarate, 10^{-4} M thiabendazole	77·6 (5)	97·0	62·9
NADH, fumarate, 10^{-3} M thiabendazole	25·4 (5)	31·8	20·6

The rate of NADH oxidation was measured spectrophotometrically at 340 nm. The assay contained, in 3·0 ml., 0·4 M potassium phosphate buffer (*p*H 7·0), particulate fraction (about 0·1 mg protein), 10 μmole $MgCl_2$, 0·3 μmole NADH and 10 μmole sodium fumarate as indicated. The thiabendazole was added in 0·1 ml. ethanol. The results are expressed as means, the number of observations being shown in parentheses.

Various concentrations of thiabendazole were found to inhibit the rate of NADH oxidation in the presence of fumarate (Table 1). The increase in rate of NADH oxidation caused by the addition of fumarate was completely eliminated in the presence of 10^{-4} M thiabendazole. Increasing the concentration of thiabendazole to 10^{-3} M further inhibited the rate of NADH oxidation, suggesting that the anthelminthic inhibited both the fumarate reductase and the NADH oxidase.

To determine whether thiabendazole reduced the rate of NADH oxidation by oxygen, NADH oxidase was assayed polarographically with a Gilson Medical Electronics 'Oxygraph' (Table 2). Thiabendazole was found to inhibit moderately the NADH oxidase activity from *H. contortus*, but much of the inhibitory effect of thiabendazole on NADH oxidase could be attributed to the small inhibitory effect caused by the ethanol in which the thiabendazole was dissolved. The inhibition was much less marked than the inhibition of the rate of NADH oxidation in the presence of fumarate (Table 1).

Table 2. EFFECT OF THIABENDAZOLE ON NADH OXIDASE

Addition	Rate of O_2 uptake nmole/min/mg protein	Percentage inhibition
None	56·3 (9)	—
NADH	487·6 (9)	0
NADH, $1·2 \times 10^{-3}$ M thiabendazole	294·5 (5)	39·6
NADH, 0·1 ml. ethanol	346·2 (4)	29·0

The rate of oxygen uptake was measured polarographically. The reaction vessel at 37° C contained, in 2·5 ml., 0·035 M potassium phosphate buffer (*p*H 7·4), particulate fraction (about 0·1 mg protein), and 5 μmole NADH as indicated. The thiabendazole was added in 0·1 ml. ethanol. The results are expressed as means, the number of observations being shown in parentheses.

These results suggest that the fumarate reductase system is much more susceptible to thiabendazole than is NADH oxidase. This conclusion was confirmed by measuring the rate of NADH oxidation by fumarate under anaerobic conditions (Table 3). NADH was not oxidized, except after the addition of fumarate. This fumarate reductase activity was completely inhibited by 10^{-3} M thiabendazole. Ethanol had little effect on the fumarate reductase activity. The inhibitory effect of thiabendazole was found to be partially relieved by high concentrations of cysteine, which suggests that thiabendazole may be reacting with a sulphydryl group involved in the fumarate reductase mechanism.

Table 3. EFFECT OF THIABENDAZOLE ON FUMARATE REDUCTASE

Addition	Rate NADH oxidation nmole/min/mg protein	Percentage inhibition
None	0 (11)	—
Fumarate	100·1 (11)	0
Fumarate, 10^{-3} M thiabendazole	0 (5)	100
Fumarate, 10^{-3} M thiabendazole, $3·3 \times 10^{-3}$ M cysteine	55·9 (5)	55·8
Fumarate, 10^{-3} M thiabendazole, $3·3 \times 10^{-4}$ M cysteine	0 (4)	100
Fumarate, 10^{-3} M thiabendazole, $3·3 \times 10^{-5}$ M cysteine	0 (2)	100

The assay conditions are as described in Table 1, except that the compartments of the spectrophotometer containing the samples were gassed with oxygen-free nitrogen (100 l. min) before and during the determination. The results are expressed as means, the number of observations being shown in parentheses.

The role of fumarate reductase in the overall metabolism of *H. contortus* has not been determined, but it is likely to be as important in the re-oxidation of NADH and in the production of ATP as it is in many other helminth parasites. It is a mechanism which is confined to the parasite in the host–parasite relationship and therefore ideally placed for anthelminthic action.

Another anthelminthic, tetramisole, has also been shown to inhibit the fumarate reductase mechanism in helminths (ref. 11 and my unpublished results). New anthelminthics which specifically act on the fumarate reductase system of parasitic helminths could be developed on a rational basis. In addition, potential anthelminthics could be screened by observing their effects, *in vitro*, on the fumarate reductase system of helminths. This would require only small amounts of the chemical under investigation, leading to substantial economies in the production of chemicals for screening.

I thank Mr D. R. Hennessy for technical assistance.

Species Specific Aggregation of Dissociated Sponge Cells

CURTIS has suggested that the initial phase of aggregation of a mixture of cells from *Haliclona occulata* and cells from *Halichondria panicea* is not species specific, and he has questioned the general validity of descriptions of species specific aggregation in marine sponges[1]. Although aggregation is not totally specific in many combinations, it is so in some cases, including the one noted above[2,3]. I have evidence to support the assertion that species specificity is complete in certain combinations of cells, and to question the applicability of the indirect test for specificity used by Curtis.

Wilson described species specific aggregation of dissociated sponge cells[4] when he observed that mixed cells from two species of different colours formed aggregates of one or the other colour. There is no reason to question this observation: the important question is, How do these cells arrive at this configuration? In many cases the initial phase of aggregation is not specific[2,3] and sorting occurs only after this phase, if at all.

I have examined combinations in which aggregation is completely species specific from the beginning. Of these only mixtures of cells from *Microciona prolifera* and *Haliclona occulata* have been studied extensively. This combination was chosen because the species are different colours and because virtually all cells of both species are well pigmented. I have generally used an ecological variant of *Haliclona occulata* which can be bright lavender when it grows near the low tide mark. *M. prolifera* is bright red, so the colour difference is very distinct and the species of most of the single cells in a suspension can be distinguished.

Microscopic observation, especially by time lapse photography (films available, see ref. 5), of the initial phases of aggregation of a mixture of *M. prolifera* and *Haliclona occulata* cells shows that single cells aggregate species specifically. While two cells of the same colour form the close association described by Wilson[4] as "coalescence", cells of different colours rarely form any kind of stable association. They often bump into each other, but there is no evidence of the establishment of a closer association. The films show clearly that the cells of *M. prolifera* and *Haliclona occulata* behave selectively from the beginning of aggregation. It is more difficult to be certain how many cells in the mixtures make "mistakes". In rare cases cells of different colours seem to adhere for an extensive interval. These examples in the time lapse films[5] where cells of one species emerge from an aggregate containing mostly cells of the opposite species. The significance of such "mistakes" is not clear, but they do not invalidate the general selectivity shown by more than 95 per cent of the cells. Curtis raised the possibility that the cells of the two species do not aggregate at the same time. Even casual observation of aggregation of mixtures of *M. prolifera* and *Haliclona occulata* eliminates this suggestion, and it is refuted by the time lapse films[5].

Species specific aggregation of mixtures of cells of *Haliclona occulata* and *Halichondria panicea* is not documented as extensively as for *M. prolifera* and *Haliclona occulata*, but the basic observations are the same using lavender specimens of *Haliclona occulata* and yellow-brown specimens of *Halichondria panicea*. If the lavender variant of *Haliclona occulata* were not available, it would be impossible to carry out direct observations, for the cells from *Haliclona occulata* and *Halichondria panicea* usually look very similar. The indirect assay used by Curtis to test specificity is based on the fact that aggregation is dependent on cell collision which is a second order reaction, the rate of which is affected by the concentration of the cells. A dilution of the reacting cells, which occurs when cells from two species which show specificity are used, should result in a lower rate of aggregation. Curtis, however, did not demonstrate that aggregation was following second order reaction kinetics in the conditions he used.

My data suggest that the rate of aggregation is dependent on the gradual resynthesis of cell surface macromolecules necessary for aggregation[6]. Treatment with ethylene diamine tetraacetic acid (EDTA) completely and irreversibly destroys the activity of these molecules. Because Curtis's test was conducted on cells treated with EDTA they must have had to replenish these macromolecules in order to reaggregate. My experiments with cells subjected to this treatment show that aggregation is much slower in such cells. Mechanically dissociated cells still have the macromolecules necessary for aggregation and they aggregate more rapidly than cells dissociated by removal of divalent cations. The macromolecules can, however, be isolated and returned to these cells, which then also aggregate much faster than cells which have to resynthesize it.

Consideration of the actual kinetics of aggregation becomes very complex if it involves several serial reactions including the conversion of a freshly dissociated cell, C, to a cell, C*, capable of adhering, and the collision of two cells to form an aggregate CC*. These two reactions can be diagrammed according to two schemes depending on the assumption made about capabilities of cells to adhere

$$(A)\ (1)\quad C \xrightarrow{k_1} C^* \qquad (B)\ (1)\quad C \xrightarrow{k_1} C^*$$

$$(2)\quad C + C^* \xrightarrow{k_2} CC^* \qquad (2)\quad 2C^* \xrightarrow{k_2} CC^*$$

In scheme *A*, the two cells in a collision can adhere even if only one has resynthesized its cell surface molecules; in scheme *B*, cells in a collision can adhere only if both cells have resynthesized their cell surface molecules. Although the kinetics predicted in these two cases are very complex even with simplifying assumptions, and are substantially different, the rate of aggregation in both is dependent principally on the rate of reaction 1 when k_1 is much smaller than k_2. Because reaction 1 is not dependent on the concentration of the cells, the test for specificity would not work in such conditions. Whenever the test is used, therefore, it must be used under conditions where k_2 is smaller than k_1 so that the rate of the reaction is completely concentration dependent.

Although the rate of aggregation need not be concentration dependent, it should be easy to set up the test for specificity in such a way that the rate of aggregation is dependent on reaction 2, which is the second order reaction dependent on cell concentration. Mechanically dissociated cells should aggregate in this way. Aggregation may, however, be more complex than expected, so it is necessary to demonstrate that the rate of aggregation is actually concentration dependent before the test can be accepted, even with cells whose adhesion is believed to be limited only by collisions.

This work was supported by a US National Science Foundation grant. I thank Drs Pierre Henkart and

Steven B. Oppenheimer for discussions on aggregation kinetics.

One-dimensional Pattern found in Blue-Green Algae

MANY filamentous blue-green algae, when grown in the absence of combined nitrogen, produce morphologically distinct cells (heterocysts) "often at more or less equal intervals" along the filaments[1]. In the presence of combined nitrogen, heterocysts occur only rarely in the algal filaments[2]. Fogg therefore proposed[2] that the formation of a heterocyst from a vegetative cell occurs when the concentration within the cell of a specific nitrogenous inhibitory substance, either ammonia or a simple derivative of ammonia, falls below a critical level. In accordance with this hypothesis there is evidence that the heterocyst is the site of nitrogen fixation in the algae[3], but this has been challenged[4]. The possibility that the concentration of a simple nitrogenous compound could determine spacing of heterocysts suggested a biochemical approach to the problem and provoked this study of the pattern in *Anabaena cylindrica*, the organism used for most earlier studies. A heterocyst pattern emerged in filaments within 12–16 h (that is, within about two-thirds of the doubling time of the organism) of their transfer from medium containing ammonia (+N medium) to medium lacking combined nitrogen (−N medium). It therefore seemed possible that the pattern was preformed in filaments grown in +N medium. Further study has confirmed this. I have demonstrated that a visible regular pattern of presumptive heterocysts is present in filaments grown in +N medium and that this pattern corresponds to that in filaments from −N medium.

A. cylindrica (Cambridge Culture Collection No. 1415/2) was grown axenically in plugged 250 ml. conical flasks containing 75 ml. of a defined salts medium[5] (−N medium) at 24° ± 1° C in an orbital shaker (200 r.p.m.) illuminated by 2 × 30 W warm-white lamps, and in an atmosphere of air containing 3 per cent CO_2. For growth in the presence of ammonia −N medium was supplemented with 0·02 per cent NH_4Cl (+N medium). The −N medium was inoculated with 3–4 day −N cultures, and the +N medium with 2–4 day +N cultures. The doubling time of the organism was 18–20 h.

Fig. 1*a* shows part of a typical filament from a 72 h −N culture. A close pattern of heterocysts and presumptive heterocysts ("proheterocysts"[7]) is apparent. Sixty to seventy-five per cent of non-vegetative cells in such filaments were recognizable as mature or maturing heterocysts[6]. A histogram of distances from each heterocyst or proheterocyst to the next (inter-heterocyst distance) in typical filaments from a young −N culture is shown in Fig. 2 (−N). The mean inter-heterocyst distance is six cells. As a measure of the regularity of the pattern let $R = 2\rho\bar{r}$ (by analogy with Claxton[8]), where ρ = density of heterocysts and proheterocysts and $\bar{r}$ = mean nearest neighbour distance. Thus with $\rho = \frac{1}{7}$, R has a value of 1·07 for a random distribution and attains a maximum value of 2 for a perfectly regular pattern. For young −N cultures $R = 1{\cdot}70$, indicating that the pattern has a strong tendency to regularity.

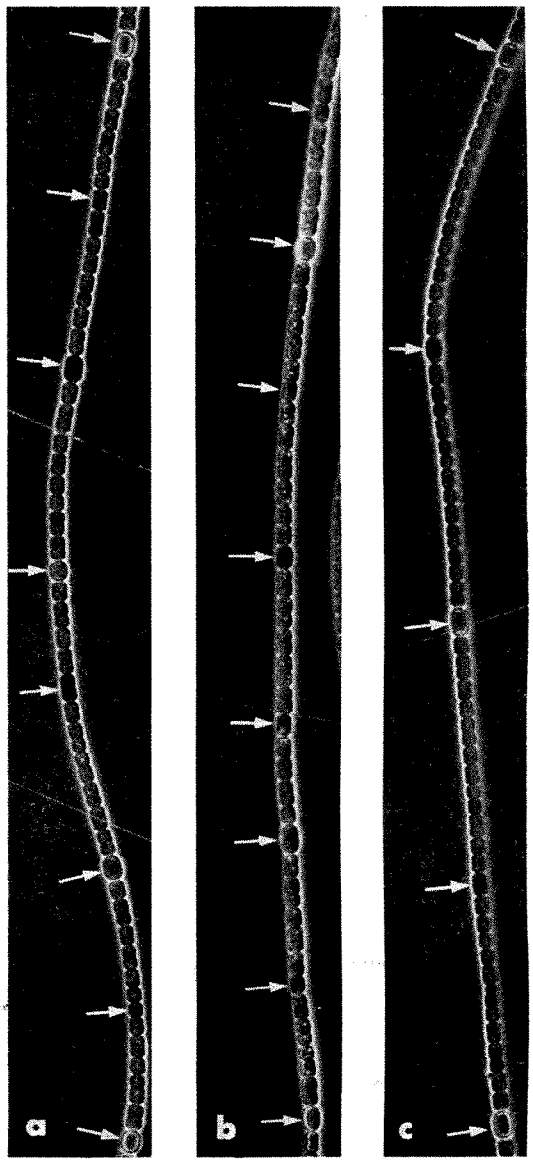

Fig. 1. Phase contrast light micrographs of filaments of *A. cylindrica*. (*a*) 72 h −N culture, (*b*) 36 h +N culture and (*c*) 8 day −N culture. Heterocysts and proheterocysts are indicated by arrows. ×460.

Proheterocysts are also present in filaments from 24–48 h +N cultures (Fig. 1*b* and ref. 9). The pattern spacing of all non-vegetative cells is similar to that found in −N cultures (Fig. 2, +N). $R = 1{\cdot}72$; mean inter-heterocyst distance = six cells. In such cultures, however, only 14 to 20 per cent of the differentiated cells are clearly heterocysts. Of the remainder, some, although distinctive (characterized by their grey appearance and relative loss of granularity[9]), could not be positively identified by direct observation as proheterocysts. It was necessary then to show that these cells were in fact presumptive heterocysts. This was accomplished by using time-lapse photography to observe the development of early proheterocysts in individual filaments which had been transferred from +N medium to thin layers of −N medium solidified by the addition of 1 per cent agar. Almost invariably these cells developed into heterocysts. Thus the pattern visible in early +N filaments is a partially expressed heterocyst pattern.

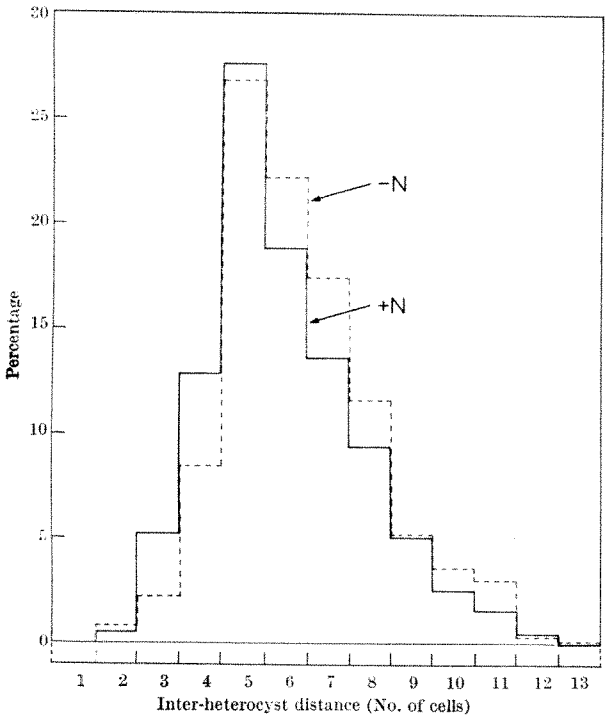

Fig. 2. Distribution of inter-heterocyst distances in filaments from early −N and +N cultures. Samples were taken from 72 h −N and from 36 h +N cultures and filaments were observed and inter-heterocyst distances (in numbers of cells) counted at × 400 magnification using phase contrast. A minimum of 200 inter-heterocyst distances (from a minimum of ten filaments) was counted in each case. The histogram is a plot of the number of occurrences (expressed as a percentage, ordinate) of each inter-heterocyst distance (abscissa). Inter-heterocyst distance means the number of vegetative cells between adjacent morphologically distinct cells; that is, heterocysts and all classes of proheterocysts were taken as equivalent. As growth is asynchronous in these conditions, cells in various stages of division were counted as one cell. These counts correlated in all cases with the actual distances in microns (determined by measurement following photography).

Although no systematic study of the heterocyst pattern in *A. cylindrica* has appeared in the literature, measurements of heterocyst frequency have been reported[2,10]. In the main, these reports indicate a larger mean inter-heterocyst distance than that described here. Some, but not all, of this discrepancy can be explained by my inclusion of all proheterocysts in the pattern, whereas the earlier reports dealt only with mature or maturing heterocysts. In addition I have found that the visible pattern widens appreciably with age of both +N and −N cultures. For example, in 4–5 day +N cultures and 7–10 day −N cultures the mean inter-heterocyst distance is about ten cells compared with six cells in young cultures. A typical 8 day −N filament is shown in Fig. 1c. At present, it is not clear whether this observation represents a true widening of the pattern, or merely reflects a slowed rate of heterocyst development relative to the rate of division of the vegetative cells. It is interesting that transfer of wide patterned −N filaments to fresh −N medium leads to the re-emergence of the close pattern within 12–18 h. Further observations on the growth and differentiation of individual filaments may help to resolve this question.

This study shows that a comparable pattern of heterocysts and proheterocysts exists in filaments grown in the absence and presence of ammonia. Fogg's hypothesis[2] therefore seems unlikely to be correct, for it contains implicitly the assumption that the production of a simple nitrogenous compound by heterocysts leads to the setting up of an inhibitory zone around them, thereby ensuring the preservation of the pattern in growing filaments. Proheterocysts, which constitute 80–90 per cent of the non-vegetative cells in +N cultures, seem unlikely to fulfil such a function. Their inability to reduce tetrazolium or silver salts suggests that they do not contain the high levels of reducing power found in heterocysts[3] and necessary for nitrogenase activity. This is corroborated by the finding that +N cultures possess no detectable nitrogenase activity when assayed by the acetylene reduction method[3]. Although it is therefore unlikely that proheterocysts are capable of fixing nitrogen, it is possible that they are involved in some other aspects of nitrogen metabolism. More knowledge of the biochemical changes occurring when a vegetative cell develops into a proheterocyst and of the role of the heterocyst may lead to insight into the mechanism underlying the transmission of positional information along the filaments. Currently we are seeking evidence of chemical and biochemical changes which can be correlated with altered patterns found in some mutants of *A. cylindrica*.

I thank Peter Lawrence and Graeme Mitchison for helpful discussions, and Sydney Brenner, who stimulated my interest in this problem.

Further Evidence for Reduced Role of Photorespiration in Low Compensation Point Species

MOST plant species cannot show a net photosynthetic uptake of CO_2 when the CO_2 concentration of the surrounding atmosphere falls below about 50 p.p.m., because at this point photosynthetic carbon fixation is reduced by lack of substrate to the rate at which CO_2 is being released from the plant by photorespiration. The concentration of CO_2 at which this occurs is called the CO_2 compensation point. A few species, including such important crop plants as *Zea mays*, have unusually low CO_2 compensation points, typically near zero. Such plants may not photorespire, or alternatively may be capable of refixing all the photorespired CO_2 by an unusually efficient photosynthetic mechanism.

The discovery in *Zea* of enzymes normally associated with photorespiration has been interpreted to mean that its low compensation point results from efficient refixation of photorespired CO_2 (ref. 1). This appears to be at variance with the observation of Goldsworthy[2], later confirmed by Zelitch[3], that in conditions where photorespiration is inhibited, both high and low compensation point species have similar affinities for externally supplied CO_2. It was thought possible, however, that the two kinds of species may have differing potentialities for the fixation of photorespired CO_2, which would, of course, be generated internally. Because, in low compensation point species, most of the photosynthetic tissue is arranged in two concentric layers of cells surrounding the vascular bundles[4], this hypothesis was tested by examining the ability of such species to fix CO_2 supplied through the vascular bundles.

The upper portion of a leaf of *Zea mays* var. 'Golden Bantam', about 40 cm² in area, was excised under water

and its base placed in a vial containing 0·05 M $NaH^{14}CO_3$. The surface of the liquid was covered with a 0·7 cm thick layer of corn oil to prevent direct $^{14}CO_2$ exchange with the atmosphere. The leaf and vial were enclosed in a chamber 550 ml. in volume at 25° C and illuminated at 600 foot candles from a tungsten source. The chamber was flushed at 500 ml. min^{-1} with 350 p.p.m. CO_2 in nitrogen for 2 h. The $^{14}CO_2$ released by the leaf was determined by bubbling the effluent gas through 1·0 M ethanolamine and counting aliquots. At the end of the period the leaf was blotted lightly to remove adhering isotope and homogenized in 0·1 M ethanolamine. Aliquots of the resulting homogenate were counted. The ^{14}C released by the leaf as CO_2 was expressed as a percentage of the total ^{14}C taken up. The whole experiment was then repeated using a leaf of similar size and shape from the high compensation point plant, *Phragmites communis*.

Table 1. CO_2 RELEASE IN LOW OXYGEN

Material	Leaf area (cm^2)	Bicarbonate taken up (μmoles)	Percentage of bicarbonate released as CO_2
Zea	43	26·5	7
Zea	40	26·0	6
Zea	46	30·7	9
Phragmites	44	18·0	6
Phragmites	52	14·3	6
Phragmites	43	22·1	11

The results of a number of experiments can be seen in Table 1. In low oxygen conditions both species released about 6 per cent of the radioactive carbon incorporated into the atmosphere as CO_2. The radioactivity remaining in both types of leaves seemed to be almost entirely in the form of photosynthate, for no significant loss of radioactivity occurred when the alkaline leaf extracts were acidified and boiled. We may therefore conclude that, when photorespiration is inhibited, the rate of fixation of CO_2 originating within the vascular bundles is of the same order in *Zea* and *Phragmites*.

When, however, these experiments were repeated using air containing 350 p.p.m. CO_2 in place of the nitrogen, the amount of $^{14}CO_2$ released from *Phragmites* increased several-fold, whereas that released from *Zea* was virtually unaffected. These results (Table 2) suggest that it is photorespiration which, by permitting the oxidation of photosynthate, causes *Phragmites* to become inefficient in fixing internally derived CO_2.

Table 2. CO_2 RELEASE IN 21 PER CENT OXYGEN

Material	Leaf area (cm^2)	Bicarbonate taken up (μmoles)	Percentage of bicarbonate released as CO_2
Zea	32	9·2	4
Zea	50	15·3	6
Zea	50	19·9	8
Phragmites	31	5·5	28
Phragmites	38	11·5	31
Phragmites	38	8·7	20

Because *Phragmites* can fix internally derived CO_2 as efficiently as *Zea* when its photorespiration is inhibited, the low compensation point of *Zea* may be explained by a lack of photorespiration, either in the whole leaf, or in at least the outer of the two layers of photosynthetic tissue surrounding the vascular bundle. The hypothesis that it is only the outer layer, the so-called mesophyll, which does not photorespire is extremely attractive, for the enzymes of photorespiration appear to be concentrated in the inner of the two layers, the so-called bundle sheath[1]. Further, it seems that the main Calvin cycle activity of the leaf is also located in the bundle sheath[4–6] and it is believed that the substrate for photorespiration is derived from the Calvin cycle[7].

We might speculate that low compensation point species photorespire as much as high compensation point types, but because their photorespiring tissue is surrounded by a non-photorespiring photosynthetic layer, they are able to refix all the photorespired CO_2, without loss, before it can reach the external atmosphere. This seems unlikely because no significant increase in net photosynthesis at low light intensity occurs in low compensation point species when photorespiration is inhibited by lack of oxygen[8,9]. Light energy is required by photorespiration in order to carry out the conversion of serine to carbohydrate[10,11], and also for the refixation of the photorespired CO_2. This energy could not then be available for the fixation of fresh CO_2. Thus we would expect inhibition of photorespiration in light limiting conditions to result in an increase in the rate of both gross and net photosynthesis, the increase in the latter being equivalent at least to the normal rate of photorespiration. The fact that no significant increase occurs[8,9] suggests that photorespiration plays only a very minor part in low compensation point species. This is confirmed by Zelitch's[12] observation that, in conditions where its oxidation is inhibited, the rate of synthesis of glycollate in *Zea* is only a small fraction of that found in the high compensation point species tested. Glycollate seems to be the primary substrate for photorespiration, and it does not normally accumulate in photorespiring tissues[12], so that its rate of synthesis should be the factor which normally limits the rate of photorespiration. The low rate of glycollate synthesis in *Zea* suggests, therefore, that this organism has but a low rate of photorespiration.

To some extent, low photorespiration in low compensation point species could be explained by postulating that if only a proportion of the leaf cells, for example those in the bundle sheath, photorespire, then the photorespiration of the whole tissue would be reduced on a *pro rata* basis. It is doubtful, however, if this would be sufficient to explain the almost total lack of effect of low oxygen on net photosynthesis. We believe the most likely explanation is an additional effect attributable to the C-4 carboxylation pathway. This pathway would be expected to generate CO_2 from malic acid within the bundle sheath chloroplasts[4,5]. Should this result in a higher concentration of CO_2 within these chloroplasts than would be normal in a true "Calvin plant", then it could result in the partial inhibition of glycollate synthesis. This has been observed in many other tissues[13–16].

Our results indicate that the carboxylation reactions of *Zea* and *Phragmites* are about equally efficient at fixing internally derived carbon dioxide. The differences in compensation points are explained as a lack of photorespiration in the mesophyll layer, and the possible partial inhibition of photorespiration in the bundle sheath of low compensation point species.

Book Reviews

ENGINEER AND SCIENTIST

Osborne Reynolds and Engineering Science Today

Edited by D. M. McDowell and J. D. Jackson. (Papers presented at the Osborne Reynolds Centenary Symposium, University of Manchester, September 1968.) Pp. xiii + 263. (Manchester University: Manchester, September 1970.) 72*s*.

OSBORNE REYNOLDS was appointed first professor of engineering at Owens College, Manchester, in 1868 at the age of twenty-seven, and this book consists of the papers presented at a symposium held at the Victoria University of Manchester in 1968 to commemorate the centenary of that historic appointment. It is prefaced by a paper in which Jack Allen, professor of engineering at the University of Aberdeen, most ably summarizes Reynolds's life and work. This is followed by nine papers, each written by an expert, dealing with the different fields of research in which Reynolds so fruitfully engaged during his lifetime at the college and indicating the important developments which have stemmed from them.

The influence of science and scientific method on British engineering practice in the nineteenth century is a fascinating subject for debate. To say which came first, the science or the engineering, is very like the problem of the chicken and the egg. In my opinion, the great pioneer engineers of the late eighteenth and early nineteenth century relied far more on intuition based on practical experience than on exact science. The very success of these empirical methods led the British engineer to affect a certain contempt for the scientist as an unpractical theorist, an attitude which contributed not a little to the loss of British supremacy in engineering. That Reynolds was fully alive to the danger of this attitude he made clear in his introductory address at Owens College in 1868 when he said: "There is plenty for the British engineer to do, and for the British workman too, but they must both look out. They have enjoyed monopoly for a long time, and now their neighbours are wishing to taste their good things. . . . We have much of our capital locked up in plant which has become antiquated; and many of the systems in vogue in our workshops have been handed down to us by our fathers, whilst our friends over the water have the advantage of a fresh start. To supply their want of skilled engineers and workmen, they have founded schools to give technical instruction, combined with a scientific education and . . . they have created a class of men which does not exist in this country, eminently qualified to hold their own at a time when science is every day taking deeper hold on all our manufactures."

It is arguable that this warning, so clearly sounded by Reynolds more than 100 years ago, was not fully heeded in Britain until after the Second World War. The sequence of events seems to have been that the British engineer, having created the hardware by guess and by God, became self-satisfied with his handiwork and neglected until too late to subject it to scientific study and scrutiny with a view to determining the fundamental mechanical laws governing its structure and operation.

Of this fundamental and long overdue applied research Reynolds was a pioneer. He was also a bridging figure because he was primarily a practical engiener in spite of his great scientific and mathematical attainments. With him, the theory never preceded practical experiment; it was always the other way round. He was a master at devising ingenious practical experiments, and it was upon the results so derived that his great contributions to engineering theory were based. His study of the lubrication of bearings fully justifies the claim that he was the founder of modern tribology, while his work on estuarial flow with scale models had world wide influence and was the seed from which the present Hydraulics Research Station at Wallingford sprang sixty years later.

Like all men of genius, Reynolds had his curious blind spots. As early as 1875–76 he experimented with a small axial flow multi-stage steam turbine with a rotor diameter of six inches running at 12,000 r.p.m. In this he anticipated Sir Charles Parsons, but he apparently lost interest in the steam turbine because he judged that it could never compete with a reciprocating steam engine owing to the extravagant steam consumption of his model. This was evidently caused by leakage of steam arising from the relatively large clearance between the blades and the casing, and it is strange that it should never have occurred to a mind so acute that this source of leakage would greatly diminish relative to an increase in the size of the turbine. But for this lapse he might have anticipated Parsons in the invention of the steam turbine. Professor Allen conjectures that Reynolds may have been influenced subconsciously by the great affection he felt for the steam engine. Whether this is true or not, such near misses on the part of men of genius are one of the fascinations of engineering history.

Considering his stature as an engineer-scientist Reynolds is surprisingly little known. Perhaps his greatest contribution to knowledge was made in the field of fluid mechanics, yet even here I wonder how many of those familiar with the term "Reynolds number" know anything of the man behind the term. It is to be hoped that this book will help to restore Reynolds to his true position as a great pioneer and original thinker.

L. T. C. ROLT

INSIDE A COMPANY

A History of the Marconi Company

By W. J. Baker. Pp. 414 + 23 plates. (Methuen: London, September 1970.) 100*s*.

THE study of the relationships between science, technology and economic growth that have attracted the attention of both scholars and politicians since the end of the Second World War has been continually frustrated by lack of appropriate data on industrial innovation. This shortage has been particularly acute in the area of contemporary industrial history. Histories abound of the textile and steel industries of the industrial revolution, but up to date accounts of modern technological developments like petrochemicals, electronics and aviation seem to have been largely ignored by the current generation of historians.

W. J. Baker's new history of the Marconi Company is a much appreciated addition to this neglected area of research. Although the author is an "insider" in that he has been an employee of the Marconi Company for many years, he is careful to point out that the book is not a product of company sponsorship and "the 'downs' are recorded as well as the 'ups' ".

The first section of the book is a detailed account of the early history of the company and traces events from Marconi's early years through the trial and tribulations of the embryonic company, up to the end of the First World War.

In the second section, the author discusses the Marconi Company's involvement in the development of the international broadcasting network, the birth of the BBC and the launching of the world's first television service.

The impact of the rapid growth of the electronic industry on the company, both organizationally and technically, forms the major part of the discussion in the third section.

Throughout the text the author has taken pains to relate the developments in technology to the overall philosophy of the firm which Marconi started and gives much detailed information on the individuals responsible for the successive transformations which the company underwent. In his summary the author concludes that the company has flourished during the seventy year period largely because of "top quality in engineering craftsmanship and materials; a thorough training of youth for the future and a generous feedback of profits into research and development".

It is to be hoped that this work will stimulate other historians to undertake the essential task of compiling contemporary industrial histories which alone can provide the basis of more analytical work on the relationship between technology and industry. MICHAEL GIBBONS

PRAGMATIC ECONOMIST

Papers on Planning and Economic Management

By Ely Devons. Edited by Alec Cairncross. Pp. vii + 278. (Manchester University: Manchester, September 1970.) 60*s*.

ELY DEVONS was not one of the leading theorists of his generation. Reared in the traditional political economy mould of the University of Manchester he bore the stamp of that institution throughout his career. Ever sceptical of high-flown theories and acutely aware of the dangers that arise from divorcing fact and theory, Devons was, by his very nature, a pragmatic man ready to see issues at their face value and anxious to analyse problems simply but positively. He was probably too wide-ranging in his thoughts and writings ever to be a leading theorist, and in any case he was happy to let the facts speak for themselves rather than to devise hypotheses or theories about what might happen outside reality. He was also too busy teaching and looking after successive intakes of students to have much time left for intensive research.

To his students (and I number one of them) Devons had an acute intellect which could cut through any problem incisively and which could also, much to the chagrin of those concerned, quickly detect the weakness of his opponents' arguments. He was sparing of words but what he had to say was expressed with great clarity. In general Devons was not content to specialize exclusively on one small area of study, though he will be best remembered for his books on planning and economic statistics. He preferred, however, to operate on a wider plane often at the frontiers where different disciplines met. Much of the time he spent debating general issues relating to economic management, planning, administration, and, later, university affairs, and the essays in this volume (introduced with a memoir by Professor Cairncross) reflect his interests in these matters. Many readers may regard them as rather lightweight, and it must be admitted that one or two of them, especially the reviews of books, might have been left out. Nevertheless, they are nearly all worth reading again, for they show Devons's sharp grasp of essentials, his ability to analyse problems clearly, his deliberate attempt to question accepted notions and, above all, the self-critical expression of his own profession. In this last respect Devons (perhaps with tongue in cheek occasionally) was at his best, and economics and economists often came in for some hard knocks. For example, he noted the pitiful way underdeveloped countries have been bombarded with successive theories of development receiving, as they do, "ever-changing diagnosis and advice from the peripatetic group of economists tripping from one to the other giving them the benefit of the latest advances in the so-called theories of economic growth and economic development. In all this there seems to be a recklessness in putting forward newly formulated but untried theories as guides to policy".

The general reader in particular will find these essays to his liking. They cover issues of topical interest, they are elegantly written and free from professional jargon and they are spiced with sarcastic wit.

DEREK H. ALDCROFT

PLEISTOCENE TOPICS

Ice Ages

Their Nature and Effects. By Ian Cornwall. Pp. 180. (John Baker: London; Humanities: New York, July 1970.) 63*s*.

THIS book, somewhat expensive for its length and style, takes a general view of the Pleistocene ice ages. It is written for students of the natural sciences and of archaeology and for the general reader—certainly a wide field of readership. It is really an introduction to the subject and deals in an elementary fashion with the many facets of studies relating to ice ages and their changing environments—geological, geographical, biological and archaeological.

Such an introduction has a very useful part to play, especially now that environmental studies of past and present are becoming, quite rightly, more and more popular. How far does this book satisfy the requirements of an introductory text? It is certainly written in a readable style, the figures are clear and most of the plates provide helpful illustrations. But the reader is entitled to expect correct information and an up to date approach to the subject, and criticism can be made of this book on both these scores. A single example of the former will suffice: many of the distributions of plants given in the section on Pleistocene floras are incorrect.

A more important criticism is that the approach to parts of the subject is antiquated. In the section on Pleistocene fauna, we are told only of mammals, in spite of the great interest of recent work on molluscs and beetles, both of which groups are very revealing in interpreting past environments. Moreover, the account of the mammal fauna is clearly based on Zeuner's 1945 lists, and much has happened to our knowledge of Pleistocene faunas and chronology since then. Another criticism concerns the absence of any clear definitions of terms used in defining climatic periods. In the absence of such clear definitions, the author perpetuates ideas current in Pleistocene chronology some thirty years ago. Thus the idea that Penck and Brückner's classification of the Alpine sequence can be used as a stratigraphic basis for the rest of Europe is not questioned or considered. As a result, the alpine terms and the term "great interglacial" are liberally used in reference to areas beyond the Alps; it has yet to be proved that a "great" interglacial exists in north-west Europe. These difficulties partly stem from lack of definitions. Nevertheless, to the beginner in the subject it should be made quite clear that correlation of major ice advances and interglacials in the Alps, northern Europe and Britain is a subject of great difficulty, and that there is still no clearly accepted scheme of cold and temperate periods which brings these three areas together chronologically.

Another difficulty for the reader stems from the acceptance of Milankovitch's radiation curve (described as a method of absolute dating) as a basis for stratigraphic correlation. What is really required is a discussion of the stratigraphical evidence for the hypothesis that the course of the curve is related to geological events.

Apart from these considerations, the book has a reasonable coverage of Pleistocene topics. But it is unfortunate that the chronological and stratigraphical framework lacks a modern perspective, and a good opportunity for the presentation of the position in Pleistocene studies today has been lost.

R. G. WEST

WELSH GEOMORPHOLOGY

The Glaciations of Wales and Adjoining Regions

Edited by Colin A. Lewis. (Geographies for Advanced Study.) Pp. 378. (Longman: London, September 1970.) 40*s*.

THE elucidation of the part that glaciers have played in shaping the landscape requires the mind of a detective. The glacial geomorphologist must be prepared to work hard and long in his analysis of the forms and deposits left behind by the glaciers, but above all he must be able to appreciate the significance of the vital clues. That these clues are very varied in character is amply shown in this book. It is divided into twelve chapters, ten of which are devoted to the separate regions of Wales and the area around it. The introduction, by the editor, sets the scene by ranging widely over Pleistocene and Holocene chronology.

Each region is described by a geomorphologist who has a very intimate knowledge of it. Naturally their approaches to their areas differ according to the nature of the evidence, and they are by no means unanimous in their views. At times the accounts are so detailed that a reader unfamiliar with the area tends to lose the thread of the argument. J. B. Whittow discusses north-west Wales and C. Embleton describes north-east Wales. J. Worsley links the glaciation of Wales to that of the Midlands in his chapter on the Cheshire–Shropshire lowlands, which is a key area. The Lower Severn is discussed by N. Stephens, and E. Watson stresses the importance of periglacial activity in his account of the Cardigan Bay area. The Upper Wye and Usk and the Hereford basin are described by C. A. Lewis and B. H. Luckman respectively. D. Q. Bowen and B. S. John complete the area by their descriptions of south and south-west Wales. The adjacent area of the West Country and Southern Ireland is considered in the last regional chapter by N. Stephens.

F. M. Synge sums up the evidence in the final chapter. His main conclusion is that final agreement in the subject is far from achieved. In fact the diversity of views on the glaciation of Wales is the outstanding impression gained from the book. Every type of evidence is explored by the different authors. The book thus provides a useful account of possible methods of studying glacial chronology and land forms, as well as providing the latest views concerning the activity of the glaciers and the processes associated with them in Wales. The book is well illustrated by maps, sections and photographs. Many chronological correlation tables and long reference lists are included. The price of the book, however, seems rather high in view of the relatively small area covered and the obvious lack of definitive conclusions. It is of considerable value, however, as a record of the present state of knowledge in that it points out where more work is needed before there is sufficient evidence to write a consistent and more complete account.

C. A. M. KING

RURAL PASTIMES

Land and Leisure in England and Wales

By J. Allen Patmore. (Problems in Modern Geography.) Pp. 332+26. (David and Charles: Newton Abbot, September 1970.) 84*s*.

THIS book is a comprehensive study of the problems posed in Britain by the increasing demand on the country's limited resources for outdoor pastimes and pursuits. Mr J. A. Patmore details and quantifies the various ways in which the British spend their spare time in the open. There is an abundance of graphs, charts, maps and statistics which have been culled widely.

The favourite outdoor pursuits are swimming and angling. One illustration of the strength of the latter sport is that the London Anglers' Association recently paid £37,000 for fishing rights on an 8,200 yard length of the Wiltshire Avon. It is surprising to find that wild-fowlers may number as many as 500,000; it is surprising also that it is estimated that 50,000 people weekly attend meetings of foxhounds. Mr Patmore gives plentifully the sources of his information.

There are the horror figures too that are seen more often—21¼ million motor cars by the year 2000, and rural car parking at a density which will cover vast acreages. Indeed, quite understandably, the author gives a great deal of space to the way in which people use the car and to its impact on the countryside. The questionnaires, reports, and investigations on the behaviour of the motorist in the countryside are now numerous, and, generally speaking, these reach the conclusion that most visitors to the countryside are simply looking for an open space, preferably near water, where they can park the car and enjoy the view and play.

Though the shadow of the motor car hangs over the book, Patmore is not discouraged or pessimistic about the future. There are solutions, some which he rightly says may offend the precepts of rigid rural conservationists. In this category must surely come the suggestions that at Malham, between the village and the tarn, there should be widened roads with overlooks (viewpoints) and access to the famous Cove and gorge on made footpaths (tarmac or concrete?) provided with explanatory displays. Another suggestion is that there should be permitted residential development around country parks, where the enhanced site values would help to pay for the recreational provision within. Patmore is undoubtedly influenced in his solutions by what he has seen in America. The idea of the "heritage highway", a route which links places in the life of national figures or strings together a story of industrial archaeology, seems to me to be a sort of motorized nature trail in which the use of personal initiative is at a low ebb.

A greater degree of planned provision for leisure will have to be made; more thought given to the segregation of conservation areas from recreational areas, a policy for the greater spreading of holidays, and in particular some measures for taking the pressure away from the pronounced Sunday afternoon peak. Patmore deals with all these and many other problems in a book which is interesting, useful and provocative.

GEOFFREY BERRY

STRESSES AND STRAINS

Yield Point Phenomena in Metals and Alloys

By E. O. Hall. Pp. viii+296. (Macmillan: London, July 1970.) 76*s*.

A YIELD point, in the sense in which Professor Hall uses the term, is a sharp discontinuity on a tensile stress–strain plot at which the elastic (or nearly elastic) stage is abruptly replaced by plastic deformation. The phenomenon owes its practical importance to the fact that mild steel and light alloy sheets subject to such behaviour cannot be shaped by deep-drawing or pressing without displaying unacceptable local distortions: these are due to the fact (intrinsic to yielding) that once plastic deformation begins at one point, it tends to continue there rather than spread elsewhere. Thus the superplastic alloys now being studied so intensively are at the opposite pole to alloys showing sharp yield points.

The study of yielding came to life in 1949, when Cottrell and Bilby published their detailed theory of the locking of dislocations in mild steel by "atmospheres" of carbon atoms. This theory, which in its chief features has stood the test of time, opened the way to a quantitative understanding of many mechanical features of this most

important of engineering alloys, and it was soon supplemented by the equally fruitful discovery by Petch and Hall (the author of the book under review) of the relationship between yield stress and grain size. The study of yielding built up to a peak in the early sixties, since when the impetus has gradually departed, leaving, however, a very substantial body of knowledge and insight. It is this material which Hall has very ably marshalled in his book.

The text begins by analysing the features common to all forms of yielding, including its propagation in the form of Lüders bands and also "false yield-points". He goes on to a very thorough disquisition on yielding, strain-ageing, quench-ageing and blue-brittleness (dynamic strain-ageing by an old-fashioned name) in iron alloys. This chapter is the core of the book. It is surprising to find that, in the author's view, the theoretical details of the strain-ageing process and the associated yield behaviour are still not entirely clear, but his conscientious literature survey certainly confirms his conclusion. This is one of the few fields of modern metallurgy where the electron microscope has failed to contribute anything of value. Later chapters deal with a range of other metals and also with the special features of hydrogen as solute. Short sections also deal with ordered alloys, whiskers, ionic crystals and semiconducting materials.

All in all, this is a very professional, thorough and notably critical survey of its field, and, indeed, its comprehensive coverage of the literature alone would guarantee it a place on the shelves of metallurgical libraries.

R. W. CAHN

CONSTRUCTION KITS

Orbit Molecular Building Set

(Designed and Manufactured by RJM Exports Ltd. Distributed by Wiley: Chichester (universities and technical colleges); Macmillan: London (schools), July 1970.) 210*s* (demonstration kit); 56*s* (student kit). (Sample kit free on request.)

Elements of Protein Synthesis

An Instructional Model. By Thomas Peter Bennett. $3. A Guide to the Instructional Model. Pp. 40. $0.75. (W. H. Freeman: San Francisco and Folkestone, 1969.)

IN an age when model building is all the craze for molecular biologists, it is important that students should be able to indulge in this art if they are to appreciate its usefulness and limitations. The *Orbit Molecular Building Set* is one of the most promising models on the market, with the advantage that it is easy to use and the student set is cheap enough for the student pocket. The atoms are precast spheres with arms at the correct bond angles and they are joined together by short lengths of plastic tubes rather like drinking straws. By cutting the straws provided into suitable lengths, any convenient scale can be chosen, from about 2 cm per angstrom upward.

The kit is best for constructing rather small assemblies such as one base pair of a DNA double helix or a short oligopeptide. It is more difficult to build complicated tertiary structures; it is not easy, for example, to construct a DNA double helix of five–ten base pairs, without knowing in some detail just what positions the atoms take up about bonds of free rotation. One difficulty is that the atoms do not rotate very freely. A space filling model would perhaps give a better idea of the real configuration of molecules, but in lieu of the ready availability of such a kit, the Orbit kit can be recommended to students who will undoubtedly enjoy piecing macromolecules together.

The *Elements of Protein Synthesis* model consists of a two-dimensional cardboard cut-out kit, with parts to represent the ribosome, mRNA, and aminoacyl-tRNA. In short, it is a sort of do-it-yourself kit for producin a moving cartoon from the types of illustration favoure in molecular biology articles in the *Scientific Americar* To suppose that this will enhance a student's understandin of how the components of protein synthesis interact i optimistic. I advise students to save their money an buy a well illustrated text.

BENJAMIN LEWIN

ONE SIDED MICROCIRCULATION

Microcirculation, Perfusion and Transplantation of Organs

Edited by T. I. Malinin, B. S. Linn, A. B. Callahan an W. D. Warren. (Proceedings of a Conference held i Miami, Florida, October 30, 1969.) Pp. xvi + 423. (Aca demic: New York and London, June 1970.) $12.50.

THIS volume is a collection of communications delivere at a conference sponsored by US Naval Research an the University of Miami. The chief aim of the conferenc was to bring together the views of clinicians and physiolo gists on the complexities of organ transplants, rejection storage and perfusion and their relation to the micro circulation.

There are three principal sections to this volume—th microcirculation under normal conditions, the patholog and pathophysiology of the microcirculation, and th perfusion of organs. In the first section, the papers ar of a general nature and no effort is made to relate ther to transplantation problems. And yet this was wha the conference was all about. The speakers in all thre sections should have met before the conference an worked out together some aspects of the theory an practice of organ transplantation because without discussion at the end of each section the communication seem isolated.

A review of the ultrastructure of freeze-cleared capil laries is interesting but of limited interest if no effort i made to relate detectable damage to functional impair ment. After all, electron microscopy has given us ver little insight into glomerular protein leakage in mos forms of the nephrotic syndrome. Considering tha arteriographic and blood flow studies, indicating th principal features of rejection of organ transplants, wer published in Europe more than a decade ago, it is sur prising that this aspect of the microcirculation was no mentioned.

Only American researchers attended this conferenc and it is exactly under such circumstances that a splendi isolationism develops. One or two references are mad to European work which is all the more absurd becaus much of the early work on the microcirculatory problen of transplanted organs appeared first in European journals Of course, most authors made it clear that they woul not be presenting an extensive list of references, and s instead of presenting confirmatory evidence of pre viously published data one is left with what could seen to be an original statement requiring confirmatio itself.

What is so refreshing about the attitude taken by som American authors is that there is always somebody ther to debunk it. F. Gollan, in his introductory remarks t "*In vivo* Perfusion of Hearts", felt constrained to stat "I do not suggest a complete or even comprehensiv bibliography in every paper in traditional physiologica fields, but I do suggest, however, that results which wer obtained by other investigators, no matter how long ag and in what country, should be examined and relie upon before subsequent experiments are proposed in th same field of investigation. The tendency in many recen publications to cite primarily only contemporary author appears to lead to much unnecessary work and reduplica tion of effort".

W. J. DEMPSTER

Correspondence

Palace and Pollution

SIR,—I was disappointed at the lack of sympathy displayed in your article entitled "Palace and Pollution" (*Nature*, **228**, 398; 1970), for the various causes being argued at "The Countryside in 1970" symposium.

It is surely hardly realistic to expect such a meeting to resolve conflicts of amenity and economic interests; though you are right to point out that practical measures must take account of the wishes of people to exploit the environment for short term sectional advantages.

In view of the prestige which *Nature* enjoys, I am sorry that your contributor felt obliged to suggest that the Duke of Edinburgh was probably misguided to publicize the view that more people lead to a meaner life for all, and I am depressed by your calm acceptance that a population rise to 70 millions in Britain is inevitable. This will be the case only if nothing is done to avoid it. The Duke of Edinburgh suggested that population growth would be much slower and might be arrested if unwanted children were never born. This is a matter of the will to encourage people to take contraceptive measures and to make the means freely available, a matter about which the Duke surely displayed greater wisdom than your contributor.

Yours faithfully,

A. C. MASON

12 Collingham Green,
Little Sutton, Wirral,
Cheshire L66 4 NX.

SIR,—In your comment on the "Countryside in 1970" conference (*Nature*, **228**, 398; 1970) you rightly draw attention to the glossing over of the relationship between the spread of affluence and environmental destruction. However, you appear to consider that this must be accepted and do not mention the other alternative to the unacceptable maintenance of inequality: the levelling down of material consumption. This may seem more desirable than the alternative you describe: the growth of population beyond 70 million, since you say that it would be unjust (to whom ?) to keep it down, and the reduction of large parts of the countryside of south-east England to "isolated pockets of greenery". Do you really believe that we should pursue our immediate ends in this way with no thought for the future ?

Yours faithfully,

JOHN DAVOLL

Chairman of the Conservation Society,
10 Broadlands Avenue,
Shepperton.
Middlesex.

Nuclear Tests and Earthquakes

SIR,—I agree with Newstead and Pile[1], that the French test on May 24, 1970, was unlikely to have "triggered" the Peruvian earthquake. It was this coincidence, however, that focused press attention on the possible connexion between bomb tests and earthquakes. I do not agree that atmospheric tests are necessarily poorly coupled to the ground, especially when conducted over water[2], nor are time delays unreasonable. Delays of many days in the build-up of seismic activity often occur near test sites and in one instance a zone of 40 km from ground zero was active following a test[3]. Whatever the mechanism might be, such delays do occur.

The frequent incidence of fairly large earthquakes in Peru is simply a measure of the seismic instability of the region. Bomb tests adjacent to such regions must remain suspect until proved harmless. The possibility of a connexion between the tests and the Peruvian earthquake cannot be dismissed by means of statistics applying to other areas.

Statistical arguments by Emiliani *et al.*[4], similar to those of Newstead and Pile, have shown a correlation between underground tests and distant earthquakes. Later work[5] has shown no such correlation. In all cases, data from bombs of all sizes and earthquakes of all sizes were used. I am unaware of any detailed analysis of large bomb tests. It is here that correlations might be expected to show, if they exist.

Healy and Marshall[5] do give a table of eleven tests with a yield of over 200 kilotons. They give the number of earthquakes recorded in 24 hour periods before and after the tests. There were five in the periods before and sixteen afterwards.

Twelve of the post bomb earthquakes were after the Stones and Bilby tests. These were the second and third tests, and the authors say that this abnormal activity "may have been contemporaneous with natural aftershocks". The measurements were made in a circle of 860 km radius around the Nevada test site. Whether or not there were effects further afield is not known. The comparatively large effects after early tests, if indeed they were not natural, lend some support to the original proposal of Emiliani *et al.*[4]. It is possible that some seismic stresses were relieved by the early tests so that later ones occurred in a more stable environment.

Further information about the Bilby test is contained in a paper by Archambeau and Sammis[6]. In Figs. 6 and 7, they show a best fit between their theory and the measured values of particle velocity. Fig. 6 is for the Rayleigh wave of period 20 s and Fig. 7 is for the Love wave of the same period. In both cases there are anomalously high values towards the east coast of the United States. These can be attributed to an anomalously high main field or to a separate disturbance. In the case of the Love wave there is also an anomaly to the north-east, on the Canadian border. It would be interesting to see similar data for other tests.

Archambeau and Sammis also show the contribution of seismic energy to the total energy released in an underground test. The question to answer is whether this release of seismic energy is restricted to the immediate neighbourhood of the source or not.

Yours faithfully,

DAVID S. ROBERTSON.

Obituaries

F. W. R. Brambell

FRANCIS WILLIAM ROGERS BRAMBELL, the zoologist famous for his work on animal reproduction, died on June 6, 1970, at the age of sixty-nine.

He was born at Sandycove, County Dublin, where as a young child he developed the interest in natural history that led him to Trinity College, Dublin, in 1918, with an entrance prize in Natural Science. There he was awarded a foundation scholarship and graduated with senior moderatorship and the gold medal for Natural Science in 1922. With a postgraduate research prize he obtained his PhD under Professor J. Bronte Gatenby.

By this time his main interest was in animal reproduction, and when in 1924 he was awarded a science research scholarship of the Royal Commission for the Exhibition of 1851, he decided to work at University College London, under Professor J. P. Hill and Professor A. S. Parkes. This arrangement was eminently successful, and led to the publication of a large group of papers on changes in the ovary caused by X-irradiation, and of the chapter on "Tissue Culture" in the 1928 edition of Bolles-Lee's vade-mecum. In 1926 he was awarded a fellowship of the International Education Board (Rockefeller Foundation), which he held at University College London until 1927 when he was offered a lectureship at King's College. He gained his DSc (London) in 1927, and in 1930, when only twenty-nine, he was appointed Lloyd Roberts Professor of Zoology at the University College of North Wales, Bangor. Here he remained until his retirement in 1968, working on the oestrus cycle and the reproduction of mammals (the common shrew, the bank vole, the lesser shrew and the wild rabbit) and on a local Enteropneust and its relatives. The first paper on what became his main study—prenatal mortality in the rabbit and the transfer of antibody from mother to young—appeared in 1942. In 1953, the Agricultural Research Council set up the unit of embryology at Bangor and appointed Brambell honorary director.

Of the many scientific and public offices that he held, he was a fellow of the Royal Society from 1947 and served on the council from 1954 to 1956. He was one of the society's royal medallists in 1964. He achieved public recognition chiefly from his chairmanship of what has always been known as the Brambell Committee, which undertook a considerable investigation of the methods used in maintaining farm animals in intensive conditions. The committee's report is a model of its kind of the consideration of the humane as well as the economic side of intensive farming. Soon after its publication, Professor Brambell was awarded the CBE.

He spent most of his retirement writing a book, *The Transmission of Passive Immunity from Mother to Young*, and seemed good for a long period of happy work. But early in 1970 he developed symptoms of a malignant disease, and in spite of extensive operations he died a few days after his book was published. His wife Margaret and his two children Anne and Michael survive him.

Dr M. J. Dijkman

DR MARINUS J. DIJKMAN, an internationally known authority on tropical agriculture and professor of tropical botany at the University of Miami, died on October 6 at the age of sixty-three.

He obtained his PhD as a plant physiologist at the University of Utrecht and began his career in 1935 as secretary to the West Java Experimental Station. Four years later he became director of the Agricultural Extension Service for South and West Sumatra. In the war he was a prisoner of the Japanese for four years and he was credited with helping to keep the mortality rate down by using his knowledge of jungle plants and insects as food and medicine. After the war, he worked as a consultant to the Netherlands Indies government for the mechanical cultivation of rice crops.

In 1947 he joined the staff of the University of Miami to work with his father in law, Dr Ochse, who was one of the world's outstanding experts on tropical economic plants. During this time Dr Dijkman initiated coffee studies in El Salvador and organized an agricultural training programme for the Pan American School of Agriculture in Zamorano, Honduras. He was made professor of tropical botany in 1953. Besides his interest in the purely practical field of improving agricultural production, he was also a pioneer in senescence and cancer research. Towards the end of his career he spent much of his time studying the effects of light on cell senescence. He was the author or co-author of a number of books including *Tropical and Subtropical Agriculture*, which has recently been reissued.

Dr Dijkman leaves his wife, Nelly, and their son Dr Dick Jaap Dijkman.

Announcements

University News

Professor J. E. Dowling, Johns Hopkins University School of Medicine, has been appointed professor of biology at **Harvard University.**

Mr P. Holgate has been appointed to the chair of statistics at Birkbeck College, **University of London.** The title of professor of psycholinguistics has been conferred on **Dr Frieda Goldman-Eisler** in respect of her post at University College. **Professor L. R. B. Elton,** University of Surrey, has been appointed visiting professor in the Department of Physics, University College. **Professor E. Shils,** University of Chicago, has been appointed visiting professor in the Department of Anthropology, and **Sir Frederick Warner,** of Cremer and Warner, consulting chemical engineers, has been appointed visiting professor in the Department of Environmental Studies.

Miscellaneous

Dr Gerald J. Wasserburg, California Institute of Technology, has received the Arthur L. Day medal of the **Geological Society of America.**

Entries are invited for the **1971 science writing award of the American Institute of Physics and the US Steel Foundation.** The $1,500 prize will be awarded for a article or book published in 1970 and intended for general readership. Entries should be submitted before January 31, 1971. Further information can be obtained from Public Relations Division, American Institute of Physics 335 East 45th Street, New York, NY 10017, USA.

The recipients of Soviet State prizes for science in 197 were announced, as is customary, on November 7, the anniversary of the October Revolution: **M. S. Ioffe** sector head at the Kurchatov Institute of Atomic Energy

B. B. Kadomtsev, R. I. Sobolev, E. E. Yushmanov, Yu. T. Baiborodov of the same institute, and **V. G. Tel'kovskii,** head of department in the Moscow Institute of Engineering Physics, for research into the instability of high temperature plasma in a magnetic field and the creation of the "magnetic well" method of stabilizing it; **Dr V. P. Silin,** laboratory sector head at the Lebedev Physics Institute, for his work on the theory of the electron Fermi-fluid of metals; **Dr E. V. Shpol'skii,** head of department in the "V. I. Lenin" Moscow Pedagogic Institute, for his discovery, investigation and implementation of fine-structure electron-oscillatory spectroscopy of complex organic molecules (Shpol'skii effect); **Dr S. V. Tyablikov,** for his monograph *Methods of the Quantum Theory of Magnetism*, published in 1965; **Academician A. G. Kolesnikov,** director of the Institute of Marine Hydrophysics of the Academy of Sciences of the Ukrainian SSR; **A. S. Sarkisyan, G. P. Ponomarenko** and **S. G. Boguslavskii** of the same institute; **G. N. Grigor'ev,** chief marine inspector of the Department of Marine Expeditions of the Academy of Sciences of the Soviet Union; **Dr S. S. Voit, Dr V. G. Kort, K. A. Chekotilo, Yu. A. Ivanov** and **V. G. Neiman** of the "P. P. Shirshov" Institute of Oceanology at the Academy of Sciences of the Soviet Union; and **N. K. Khanaichenko,** deputy director of the Institute of Biology of the Southern Seas of the Academy of Sciences of the Ukrainian SSR, for experimental and theoretical research on the Lomonosov currrent and other currents in the tropical Atlantic; **E. N. Mishustin,** head of department at the Institute of Microbiology of the Academy of Sciences of the Soviet Union, for research into soil microbiology and study of the biological fixation of nitrogen; **A. V. Artsikhovskii,** head of department at Moscow State University; **Professor V. L. Yalin** of the same university; **Dr B. A. Kolchin, A. F. Medvedev, P. I. Zasurtsev** of the Institute of Archaeology of the Academy of Sciences of the Soviet Union, and **V. I. Borkovskii,** sector head in the Institute of the Russian Language of the Academy of Sciences of the Soviet Union, for their work on the Novgorod archaeological expedition; **Dr M. F. Ternovskii** and **A. I. Teremt'eva** of the All-Union Tobacco Research Institute, for work on the hybridization of plants to produce disease-resistant strains; **Dr L. A. Lunts,** of the All-Union Scientific Research Institute of Soviet Jurisprudence, for his three-volume work, *Course of International Personal Law*, published in 1959–66, and **Academician N. N. Nekrasov,** chairman of the Council for the Study of the Forces of Production in the State Plan of the Soviet Union, and **Academician N. P. Fedorenko,** director of the Central Economic-Mathematical Institute of the Academy of Sciences of the Soviet Union, for research on the scientific problems of the development of the chemical industry of the Soviet Union.

ERRATUM. In the article "Three-dimensional Fourier Synthesis of Human Deoxyhaemoglobin at 3·5 Å Resolution" by Hilary Muirhead and J. Greer (*Nature*, **228**, 516; 1970), Fig. 2 is upside down. The part labelled *a* should be labelled *b* and vice versa.

ERRATUM. In the article "Three Dimensional Fourier Synthesis of Horse Deoxyhaemoglobin at 2·8 Å Resolution" by W. Bolton and M. F. Perutz (*Nature*, **228**, 551; 1970), the data on the left hand side of Table 1 refer to oxy and the right hand side to deoxyhaemoglobin: the printed headings should therefore be reversed.

ERRATUM. In the article "Nomenclature of Immunoglobulins" by D. S. Rowe (*Nature*, **228**, 509; 1970), column 2 of Table 1 should read

British Diary

Monday, November 16

Developments in the Science of Wood Preservation (10.30 a.m. symposium) Society of Chemical Industry, Pesticides Group, at 14 Belgrave Square, London SW1.

Inflation and Eruption of Kilauea Volcano, Hawaii, 1965–68 (5.30 p.m.) Dr R. S. Fiske, University of London, in the Chemistry Lecture Theatre, King's College, Strand, London WC2.

Space Technology and the Future (6.30 p.m.) Mr G. K. C. Pardoe, Institution of Electrical Engineers, at the University, Liverpool.

The Origins of Money (5.30 p.m.) Mr P. Grierson, University of London, at Senate House, London WC1.

The University's View of Industry (6 p.m.) Professor J. W. Linnett, FRS, Royal Society of Arts, at John Adam Street, London WC2.

Tuesday, November 17

Cardiac Metabolism (5.30 p.m.) Professor R. B. Fisher, University of London, at the Institute of Child Health, 30 Guilford Street, London WC1. (Eighth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Electronics—Its Future in Navigation (6.30 p.m.) Institution of Electrical Engineers, in the Department of Electrical Engineering, The University, Liverpool (Silvanus P. Thompson Lecture).

Nature's Messengers (3 p.m.) Professor R. King, Royal Institution, at 21 Albemarle Street, London W1. (Lecture for preparatory school pupils from Schools in London and the Home Counties. To be repeated on November 18 and 19.)

Protein from Oil (6.15 p.m.) Mr G. H. Evans, Society of Chemical Industry, Food Group and Heavy Organic Chemicals Group, at 14 Belgrave Square, London SW1.

Submarine Ignimbrites? (5.30 p.m.) Dr R. S. Fiske, University of London, in the Chemistry Lecture Theatre, King's College, Strand, London WC2.

The Automatic Landing of Aircraft (6.30 p.m.) Mr S. A. W. Jolliffe, Institution of Electrical Engineers, jointly with IERE, at Leicester Polytechnic.

The Physics of Polymerized Material (5.30 p.m.) Professor S. F. Edwards, University of London, in Mechanical Engineering Lecture Theatre A, Imperial College, London SW7.

The Use of Organometallic Compounds in Synthetic Organic Chemistry (10 a.m.–6 p.m. symposium) Society of Chemical Industry, Fine Chemicals Group, at the Royal Society, 6 Carlton House Terrace, London SW1.

This Engineering Age (5.30 p.m.) Sir Henry Jones, Institution of Civil Engineers, at Great George Street, London SW1 (Graham Clark Lecture).

Wednesday, November 18

Biochemical Aspects of Insulin Secretion and Action (2 p.m.) Dr C. N. Hales, University of London, at the Royal Postgraduate Medical School, Du Cane Road, London W12.

Chemical Magnification—Induction, Amplification and Catalysis in Analysis (6.30 p.m.) Mr A. Townshend, Society for Analytical Chemistry, jointly with the Carlett Park Chemical and Physical Society, at West Cheshire Central College of Further Education, Carlett Park, Wirral, Cheshire.

Electronics in Cars (6.30 p.m.) Mr L. G. Cripps, Institution of Electrical Engineers, at NE Essex Technical College, Colchester.

Fire Protection in Industrial Buildings (6 p.m.) Mr M. J. Smith, Royal Society of Arts, at John Adam Street, London WC2 (Alfred Bossom Lecture).

Investigations of the Liver, Spleen and Pancreas Using Radionuclides (10 a.m.) British Institute of Radiology, Nuclear Medicine Committee, in the Edward Lewis Theatre, Middlesex Hospital Medical School, Cleveland Street, London W1.

The Application of Ultrasonic Holography in Non-Destructive Testing (6 p.m.) Mr E. E. Aldridge, Institution of Electronic and Radio Engineers, Instrumentation and Control Group, at 8–9 Bedford Square, London WC1.

The Origin of the Metric System: Instruction sur les Mesures Déduites de la Grandeur de la Terre, by the Commission Temporaire des Poids et Mesures, Paris, Year 2 (1793–1794) (1 p.m.) Dr W. A. Smeaton, Royal Institution, History of Science Discussion Group, at 21 Albemarle Street, London W1.

The Simultaneous Determination of All Zeros of a Polynomial (5.30 p.m.) Professor P. Henrici (Zürich), University of London, at Imperial College, London SW7.

The Tower Subway—The First Tube Tunnel in the World (6 p.m.) Mr C. E. Lee, Institution of Mechanical Engineers, jointly with the Newcomen Society, at 1 Birdcage Walk, London SW1.

Thursday, November 19

Analytical Applications of Lasers (6.30 p.m. discussion meeting) Society for Analytical Chemistry, Midlands Section, in the Chemistry Department, The University, Birmingham 15.

Automatic Methods and Assessment of Environmental Pollution (3 p.m. discussion) Society for Analytical Chemistry, Automatic Methods Group, at the Wellcome Building, Euston Road, London NW1.

Chemical Aspects of the Sodium Pump (5.30 p.m.) Professor R. Whittam, University of London, at the Institute of Child Health, 30 Guilford Street, London WC1. (Ninth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.).

Communications Satellites (5 p.m.) Professor B. Cheng, University of London, in the New Chemistry Theatre, University College London Gower Street, London WC1.

Electronics Education in Eastern Europe (6.30 p.m.) Professor G. D. Sims, Institution of Electrical Engineers, jointly with IERE, at Bournemouth College of Technology.

High Fidelity Loudspeakers and their Evaluation (6 p.m.) Dr A. R. Bailey, Institution of Electronic and Radio Engineers, Communications Group, at 8–9 Bedford Square, London WC1.

How to Achieve the Torque Curve You Want (6 p.m. discussion) Institution of Mechanical Engineers, Combustion Engines Group, at 1 Birdcage Walk, London SW1.

Laboratory Meeting (7.30 p.m.) Royal Society of Tropical Medicine and Hygiene, at the Liverpool School of Tropical Medicine, Pembroke Place, Liverpool 3. Chairman: Professor B. G. Maegraith, CMG, FRCP.

Mineralized Fluids in Ancient and Modern Sediments (2.30 p.m.) Institution of Mining and Metallurgy, at the Geological Society, Burlington House, Piccadilly, London W1.

Ocean Currents and Their Dynamics (two-day discussion meeting) Royal Society, at 6 Carlton House Terrace, London SW1.

Progress in Organic Chemistry (2 p.m. symposium) Chemical Society, in the Scientific Societies Lecture Theatre, 23 Savile Row, London W1.

Some Investigation into Building Problems (5.30 p.m.) Mr R. T. Kelly, Society of Chemical Industry, Road and Building Materials Group, at 14 Belgrave Square, London SW1.

Stereo Transmission and Reception (6.30 p.m.) Mr J. H. Brooks, Institution of Electrical Engineers, London Graduate and Student Section, at Hatfield Polytechnic.

Systematic Application of Palynology (5 p.m.) Dr Wm. T. Stearn, Dr W. G. Chaloner and Mr A. Clive Jermy, Linnean Society of London, at Burlington House, Piccadilly, London W1.

The Frontiers of Farming (8.15 p.m.) Professor D. K. Britton, University of London, at Swanley Hall, Withersdane, Wye College, Ashford, Kent (Inaugural Lecture).

Friday, November 20

Dye-Sensitized Photo-Oxidation of Nucleotides (1 p.m.) Miss Gillian Mautner, Royal Institution, Photochemistry Discussion Group, at 21 Albemarle Street, London W1.

Gloss and Semi-Gloss Latex Paints (6.30 p.m.) Mr G. Willison, Oil and Colour Chemists' Association, at the Chamber of Commerce House, 75 Harbourne Road, Birmingham 15.

Monoamine Oxidase Inhibitors (10 a.m. colloquium) Biochemical Society, Pharmacological Biochemistry Group, at the Research Institute, May and Baker Ltd., Dagenham, Essex.

Muscular Contraction (9 p.m.) Dr H. E. Huxley, FRS, Royal Institution, at 21 Albemarle Street, London W1.

Storm Effects in the Ionosphere and Magnetosphere (2 p.m. discussion meeting) Royal Astronomical Society jointly with the Institute of Physics and the Physical Society, at the Scientific Societies Lecture Theatre, 23 Savile Row, London W1. Chairman: Professor V. C. A. Ferraro.

Monday, November 23

Building Linear Filters from Logic Circuits (7.30 p.m.) Mr M. H. Ackroyd, Institution of Electrical Engineers, at the University of Leicester

Engineers in General Management Posts—the Army's Experience (5.30 p.m.) Major General R. L. Clutterbuck, Institution of Civil Engineers, at Great George Street, London SW1.

Fire Precautions in Locomotives and Rolling Stock (5.30 p.m.) Mr J. M. Jarvis, Institution of Mechanical Engineers, Railway Division, at 1 Birdcage Walk, London SW1.

Founders of Radio-Analytical Chemistry (6 p.m.) Professor R. Spence, Society for Analytical Chemistry, Radiochemical Methods Group, at the Polytechnic of the South Bank, Borough Road, London SE1.

Microwave Ultrasonic Devices (6 p.m.) Mr R. F. Humphreys, Institution of Electronic and Radio Engineers, Aerospace, Maritime and Military Systems Group, at 8–9 Bedford Square, London WC1.

Some Aspects of the Educational System in the USSR (6.15 p.m.) Mr B. Nitikin (USSR Embassy), Institution of Electrical Engineers, in the Renold Building, UMIST, Manchester.

Will the Coelacanth Survive?

THE British Association has been in trouble of one kind and another for several years, so that the committee of review which has now been set up (see page 702) is by no means a frivolity. For a long time it has been clear that some radical reshaping of the association's function would be necessary. Moreover, it has become clear that the devices by means of which the association has in the past decade sought to extend its influence in public life by the encouragement of young scientists and the provision of public lectures, valuable though these have been, are not sufficient to provide a pattern for continued existence. So taking stock of the present and charting a course for the future is a necessary and welcome step.

What are the questions to be asked? If the committee of review is sensible, it will start with the question of what the British Association is for. Sad though it may be to see honourable institutions disappear, there is no excuse for keeping them alive simply because they exist already. And it must be said that the annual meeting which for decades has been the chief of the British Association's claims on public attention has become a muddled affair. Everybody agrees that there is no longer a need for a general forum for the presentation of new concepts in science —other institutions have now replaced the association in that way. To be sure, the annual meeting still gives pleasure to those who attend, but the number of people willing to pay for that (and able to afford a week away from home at the same time) is understandably dwindling. And the association's interest in young people and public lecturing could at a pinch be done as well by other organizations.

So what is there left to do? It is a great surprise that in the past several years the association seems almost wilfully to have neglected its own origins and the reasons which made its existence seem logical for the first fifty years or so after its foundation in 1831. Then, the association was valued not merely as a means of communication among scientists but also as a forum for the discussion of issues which are important to science as a whole and as a means of advancing causes which might help the development of science. What reason is there to believe that these functions are now less necessary than in the nineteenth century? If anything, there is now a more urgent need than ever for some means of exploring in public issues of importance to professional science and in the relationship between professional science and the wider community. The place of science teaching in British universities and the organization of the undergraduate curriculum as a whole are important public issues calling for an independent examination. Moreover, a body like the British Association could function well as a public arbiter of the quarrel between the nuclear physicists and the rest over the question whether to participate in the scheme to build a new proton accelerator at Geneva. On these and a host of other matters, the British Association, if it had the will, could play a valuable and as yet unfilled role in British public life.

Will it have the will? And will it have the courage to make the other necessary changes of organization which are necessary if such a task is to be undertaken? The first thing to be said is that the constitution of the association, hallowed by 140 years of tradition, is now quite unsuitable for the performance of any task. The interlocking series of committees which pass as its machinery of government are a means of sharing status among large numbers of people while ensuring that nobody need feel responsible. There is nowhere for Mr Harry Truman's buck to stop. It is no wonder that in the past six months, the association has been plagued with a rash of conflicts between the committees supposedly responsible for policy and the staff saddled with the thankless task of executing it.

In circumstances like these, it is also no surprise that hardworking professional scientists tend on the whole to spend their energies elsewhere than in the British Association—the association must count the continued support of many devoted professional scientists not as a mark of active respect but rather as a sign of the affection in which it continues to be held in spite of recent failings. And is it any wonder that keeping body and soul together and balancing the budget has turned out to be a daunting process?

Against this background, it must seriously be doubted whether the committee of review which is now established will be sufficiently radical in temper and sufficiently persuasive in the presentation of its eventual report to bring about the necessary reforms. The trouble is that the committee which has chosen to take responsibility for charting the future course of events is also for practical purposes that responsible for day to day management of the association's affairs. Although there is some new blood on the committee, it will evidently require an unwonted degree of courage for such a committee to acknowledge that the association's strategy for the past decade has been pusillanimous. By the same test, it will be hard for the committee to acknowledge some of its own recent folly, particularly in its dealings with staff. And finally, it is inevitable that when the committee eventually makes public its recommendations, those which argue for the continuation of present practices will seem unconvincing because they will also appear insufficiently detached. In short, it is a mistake to have chosen such an introspective method of inquiry.

Universities Once More Under Pressure

THESE are sombre times for those who would form a coherent view of the development of British universities in the next few years. To begin with, the change of government has spread a little alarm and a good deal of despondency, particularly among those who cannot easily reconcile a generous policy towards the universities with the government's apparent belief that reductions of public expenditure are innate virtues. The news that the government has also asked the Open University to study what would be involved in taking on to its books not the stream of self-improving adults for which the university was originally intended but, rather, students straight out of school has added to the sense of alarm, if only because it suggests that the government is planning to meet the demand for more higher education, commonly acknowledged to be a reality, by setting up methods of higher education which are alternatives to conventional universities.

In circumstances like these, the universities should be careful not to panic. To cry WICKED TORIES! would probably help to set the blood flowing again in the veins of many nostalgic academics but there is much more point and potentially much more profit in a radical re-examination of the present system of higher education. First, there is at least a case to be made for thinking that young people in the United Kingdom might find some benefit in a university that would allow them to obtain degrees while working at some regular job. After all, Birkbeck College in the University of London has an honourable reputation. The University of South Africa, which functions as a correspondence college and which is much despised by academics, is nevertheless a good deal better than nothing. It is true, of course, that the Open University would be better able to defend itself against an attempt at converting it into a substitute for more university places of an orthodox kind if it had had time to demonstrate that it could operate successfully with more mature students.

No amount of dickering with the Open University will, however, solve the problems with which orthodox universities are concerned. The overriding problem is how to cater for much larger numbers of students while still providing a curriculum that is at once educative and a preparation for more exacting things to come. The system proposed by Professor Brian Pippard and his colleagues (about which an article will be published next week) does point to one possible solution. Briefly, there are potential advantages in a system in which, in Britain, the usual undergraduate course lasts two years and serves as a foundation for vocational studies or more advanced scholarship. There is particular benefit to be expected from an attempt to make a liberal course for undergraduates based on science, if only because it is by now plain that the specialist curricula inherited from the time when the university system was much smaller are unsuited to the present needs of a technical society in which large numbers of people must take on work which is technical in its connexions but neither research nor development in the old sense. The universities should therefore regard the exploration of innovation of the kind now known as Pippardism with all the vigour at their command, for in the long run these are typical of the ways in which they must hope to be able to provide higher education for more people in a manner better suited for modern needs.

More Games with Numbers

DR EUGENE GARFIELD'S Science Citation Index has become not merely a bibliographical tool for a disputed phenomenon in its own right. Some weeks ago (*Nature*, **227**, 669; 1970) Dr Garfield himself argued how his compilation could be used as a basis for historical research of various kinds. The Science Citation Index is in fact a list of all the pieces of scientific literature referred to in scientific articles published in some 2,000 scientific journals with, of course, suitable references to the articles in which the items were first cited. Dr Garfield himself suggested that his compilation can be used as a means of tracing the development of new ideas through several decades of contemporary history, and this is evidently a fruitful field for research. He did however go further by suggesting that the numbers of occasions on which particular articles were cited in the literature could in some sense be taken as a measure of their importance and that—this is where the trouble begins—the productivity of individuals might be measured by the numbers of occasions on which their names are cited in the literature in any year. This is the point which has been attacked by several correspondents in the past few weeks, and which is now once more defended (see page 789) by Mr A. E. Cawkell from Dr Garfield's Institute for Scientific Information.

Where does the truth lie? What value is to be attached to the number indicating how often a particular article or the author of a series of articles is referred to in the literature? And is there any foundation in Dr Garfield's suggestion that a discriminating use of numbers like these might help to identify creative people early in their careers, to award grants and fellowships without "wasteful infighting and manoeuvring" and to provide outsiders with a sense of "where the action is"? Much depends on knowing why authors cite particular papers when writing an account of their own work. This is a subject on which much remains to be said. The chances are, however, that some kinds of articles will be more frequently cited than others because of the character and not necessarily

the importance of their contribution to the development of science. In theoretical physics, for example, authors frequently refer to accounts in the mathematical literature of the development of a new technique simply as a perfectly proper means of shortening their own account. The same is true in many other fields in which a reference to a convenient description of a standard technique may save a lot of space and explanation. Elsewhere, however, it is well known that radically innovative papers are often neglected for several years until they have somehow become absorbed in the mainstream of development—Einstein's classic paper on the stimulated emission of radiation and Onsager's calculation of order–disorder phenomena in crystal lattices are two examples of crucial papers that would hardly have shown up on Dr Garfield's index when their importance was most in need of recognition. In short, the snag in the operation of this numbers racket is the danger that, with the best will in the world on everybody's part, the numbers will merely accentuate a conventional description of "where the action is".

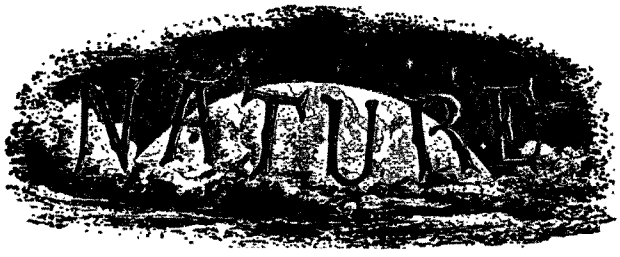
Signs of Reason

THE leader of the House of Commons, Mr William Whitelaw, has shown reason. His proposals for the select committees of the House of Commons (see *Nature*, **228**, 401; 1970) which were debated last week are much more sensible than his warnings last July about avoiding "developments which will lead to a position like that reached in the United States Congress where committees are all-important". Mr Whitelaw was then concerned to preserve the chamber of the House of Commons as the place where "true debate must take place", in the best traditions of Pitt and Disraeli, but his friends and other colleagues have luckily brought him back into the twentieth century.

What Mr Whitelaw now suggests is that the select committee system should not be allowed to mushroom to such an extent that important decisions are taken outside the chamber of the House of Commons but, on the other hand, he sensibly says that there is considerable value in maintaining a few specialist select committees to look at the workings of the executive departments. This—Mr Whitelaw may be comforted—is a system with a good pedigree. In 1918, Lord Haldane said that any increase in the efficiency of the departments of state "should have as its correlative an increase in the power of the legislature as a check on the acts and proposals of the executive". This need is probably most obvious with the Select Committee on Science and Technology, which has done much to bring to the attention of members of Parliament and the public the issues underlying decisions in the field of nuclear energy, for example, and it has also been valuable in stimulating debate outside Westminster and in the press. The reappointment of the Science and Technology committee will be welcomed; there is an obvious need for it to embark without delay on a study of the present chaos in which Britain's space research finds itself.

But is Mr Whitelaw in any case justified in holding on to his belief in the ability of Parliament to engage in productive debate? All too often the agenda is filled with matters which keep it occupied until the early hours of the morning, but even on important issues the result of a debate is a foregone conclusion. Apart from the operation of the party system, the Members of Parliament are incapable of keeping themselves fully informed of many of the issues which underlie government policy, so that debates all too often turn out to be a series of rather bald statements. An answer could be to extend the select committee system even further, by setting up *ad hoc* bodies to look into important issues as they arise. A select committee to examine the consequences of Britain's entry into the Common Market, for example, would not go amiss. But for the future, Mr Whitelaw should take careful note of the point made repeatedly in last week's debate that if a select committee is to function properly, it must have a permanent and competent secretariat and pool of knowledgeable advisers.

Emperors without Clothes



THE trouble at Rolls-Royce is a smack in the eye for British policy towards industrial development. For two decades now, the manufacture of aircraft engines has been regarded as an activity as important to the survival of the United Kingdom as the preservation of the pound sterling and (more difficult) of the white cliffs of Dover. Over the years, Rolls-Royce has paid more in taxes than it has earned by government contracts or subventions, and its export record has been splendid. Why, then, has it suddenly fallen flat on its face?

First of all, it must be acknowledged that the company has been exceedingly complacent in its belief that it would be possible always to earn a living for itself by applying a variety of high engineering skills to the manufacture of a single product, particularly when the market for that product is likely to contract and when the company could not hope to establish itself as a prime contractor in the United States as well as Britain. In terms of industrial strategy it would have been wise, more than a decade ago, to have plumped for a measure of diversity, partly as an insurance against the kind of setback which has now occurred and partly as a way of making fuller use of the skills available within the organization. This, one would have thought, is one of the simple

facts of life that an indulgent government could have spoken of to its protégé.

But would not greater diversity have blunted the flair with which Rolls-Royce was able to exploit its skill in the manufacture of aircraft engines? This is what the company would have said. Outsiders and even some of those within the company may now agree that the flair for exploiting high technology in a narrow market, which has kept Rolls-Royce going for twenty years, may in the end have been the company's downfall. How much better might it not have been to have devoted some of this skill to the manufacture of electric typewriters, sewing machines or other objects which could have been sold for a profit?

100 Years Ago

DR. MICHAEL FOSTER (the newly-appointed Prælector of Physiology at Trinity College, Cambridge) commenced on the 14th inst. his course of lectures in a part of the new museums, which has been temporarily fitted up as a Physiological Laboratory. He gave a lucid and able exposition of the three great factors of life—contractility, as evinced chiefly in muscles; irritability, as evinced chiefly in the nervous system; and secretion. Dilating upon the much-vexed question, how far these are attributable to physical agencies, or are to be referred to another agency called "Life," he compared the latter view to a fortress closely besieged by an able band of investigators who are ever narrowing its area, and pressing the physical forces closer and closer upon it. But it has not yet capitulated. No one has a right to say that it will or will not capitulate; and till it has done so we are perfectly justified in regarding it as an entity, as a something to be taken into account in the investigation and the attempts at the explanation of living processes. He should still, therefore, use the term without committing himself to either view. He gave definitions of Physiology and Morphology. He spoke of the enormous importance of vivisection to the advance of Physiology. By it Vesalius might be said to have laid the foundations of Physiology; by it Harvey had been enabled to obtain the proofs of his great discovery. Without it all that had been written on Physiology would have gone for very little, and we should still have been in the Aristotelean mists darkened by the theories of the Schoolmen. He wished, however, to state that in the teaching of Physiology it would be necessary for him to resort to it much. He stated the plan he intended to pursue in carrying out the intentions of those who had placed him in that honourable position. Lectures he did not regard as a very fructifying mode of sowing seed. He thought it far better that men should work and see for themselves. With the munificent aid of Trinity College, he hoped, ere long, to make the physiological laboratory in Cambridge one of the best working laboratories in the country. He intended to have practical classes in addition to the lectures; and students who were competent would have opportunities for private work. It would be a labour of love to him to render practical aid to those who needed it, and to promote the study of physiology by every means in his power.—

From Nature, **3**, 73, *November* 24, 1870.

OLD WORLD

SATELLITES

UK-5 to Study Cosmic X-rays

THE Science Research Council has announced that next satellite in the series being launched for Britain NASA will be designed to study cosmic X-ray sour Called UK-5—a successful launch in 1973 will re in its being renamed Ariel 5—it will be the sec satellite to be wholly manufactured in Britain. UI which should be launched in 1971, is now being built the British Aircraft Corporation, and both the sa lites will carry an experiment for a United St research group in order to obtain a relatively low launch.

UK-5 will be a squat cylinder 34 inches high 37·75 inches in diameter, its sides being almost cove with solar cells to provide electrical power. attitude of the spacecraft will be controlled by its computer in accordance with instructions from ground, so that most of the X-ray detectors can pointed at individual sources while the one-side moun experiment will scan the whole sky as the sate rotates, searching for new objects.

There will be a total of six experiments carried UK-5, two of which are the responsibility of University of Leicester group which has beer successful with other X-ray detectors. One will meas the polarization of X-rays, while the other is overall sky survey mentioned above. The Mullard Sp Sciences Laboratory is providing a proportic counter to study individual sources in the 2–30 band, while higher energy sources (up to 2 MeV) be studied by a detector designed at Imperial Coll London, to investigate known X-ray sources to, search for X-ray emission from, pulsars. Anot pointing detector, which incorporates a photomultip for detecting visible light as well as several detect intended to carry out a sky survey in the range 0·2 30 keV, is also the responsibility of the Mullard labo tory and the "guest" American experiment to Goddard Space Flight Center will search for transi effects against the X-ray background radiation.

On this occasion, the spirit of Anglo-American operation will be maintained after the launch of UK when ground based observations will be carried out the Mount Wilson and Palomar Observatories correlate the X-ray observations with simultane optical measurements. One group at the Hale Obser tories are already compiling a library of plates obtai with their 48 inch Schmidt telescope, and these will made available by the time UK-5 is in operation. Ot groups, possibly including one in Chile, will also t part in the observational programme being plann but the Hale survey will be particularly useful beca it covers the galactic plane out to a latitude of ±9°, a most X-ray sources lie in the plane of the galaxy.

This highly sophisticated satellite has been announ at a time when interest in X-ray astronomy is at height (see p. 715) and will provide just the type detailed information which is required before any gr progress in understanding high energy sources can achieved.

LUNA-17

Automatic Exploration

from our Soviet Correspondent

THE landing of Luna-17 on the surface of the Moon, and the safe deposition and operation of the Lunokhod-1 "mooncar", following hard on the heels of the Luna-16 project, show that Soviet space research is soldiering on with the first, reconnaisance, stage of lunar exploration. This stage, according to Academician B. N. Petrov (*Nature*, **228**, 6; 1970) will depend only on automatic spacecraft.

From the pictures released so far, Lunokhod-1 with its eight wheels seems to be capable of proceeding at more than one speed. There are also reports that it is "proceeding at its first velocity". The weight of the vehicle has not so far been released, but its equipment, in addition to the radio and television links needed for its control from Earth, includes a laser-reflector, developed on a basis of Soviet–French co-operation, and a number of as yet unspecified experiments.

Because of the small amount of Moon-rock (about 100 g) recovered by Luna-16, it had been suggested that the mission of Luna-17 would be merely a repetition of Luna-16. The rapid progress from the stage of simple retrieval of specimens to the operation on the lunar surface of an explorer craft indicates an acceleration in the tempo of the Soviet space programme. But the highly publicized setting up of Soviet flags and pennants, together with a portrait of Lenin, suggests that this successful attempt at a new "first" in space hardware has been undertaken for prestige as much as for scientific purposes.

INDEPENDENT UNIVERSITY

Hazy Plans command Support

by our Education Correspondent

A MEETING of supporters of the Independent University last week failed to remove most of the question marks still hanging over the proposed venture. What emerged from the meeting was a woolly idea of the possible academic policy of the institution, an even hazier picture of how it may be financed and the knowledge that the planning board is not sure whether to plump for a site very close to London or one in the country. In other words, the plans do not seem to have matured much since the idea was first discussed in January 1969 (see *Nature*, **221**, 119; 1969). One thing the meeting did demonstrate, however, is that the Independent University now commands a growing band of influential supporters—the list of patrons, for example, looks like an extract from *Who's Who*.

United in the belief that academic freedom, and in particular the freedom to innovate, are being eroded in the traditional state-supported universities, protagonists of the Independent University are attempting to set up a university free from financial ties to the exchequer. Under the chairmanship of Sir Sydney Cain, former director of the London School of Economics, a planning board has been looking at ways in which such an establishment could be financed and what sort of teaching it should go in for. The venture is expected to be financed by foundations, industry and contract research, and its students will pay their own fees.

Describing the possible academic policy of the Independent University, Professor Max Beloff, from the University of Oxford and a member of the planning board, said that the institution would stand or fall on its ability to attract good staff. The emphasis, he said, will be on intensive teaching, "which will bring out intensive learning", and the curricula will be something of a compromise between the specialist and non-specialist schools of thought—an undergraduate's first two years would be spent in general studies, while the third year would be devoted to a specialist course.

One of the chief criticisms often levelled at the proposals is that the university will not be able to support a good science faculty on a limited budget, but according to Professor G. H. Rawlcliffe of the University of Bristol, and also a member of the planning board, this attitude is a "delusion". The university, he said, will concentrate on those branches of science which do not require heavy capital expenditure, and science will be taught in a new way. It is possible, Professor Rawlcliffe maintained, to teach "science for the citizen" rather than "science for the specialist", and to teach concepts very cheaply.

But this hazy argument did not entirely appeal to Professor Philips Griffiths, of the University of Warwick, who doubted the ability of the university to attract good teaching staff without spending much money on research equipment. Other speakers also raised the question of the provision of computing facilities and there was some discussion of the viability of a two-year generalist course. But the trend of the discussion was in favour of breaking down the barriers between subjects.

Discussion of the finance of the Independent University was non-specific—little mention was made of how much the institution will need, or how much has been promised. A system of student support by loans was also talked about in theoretical terms, with Dr Margaret Woodhall of the University of London Institute of Education providing the basis for discussion with a review of the loans system in Scandinavia. It was broadly accepted that a loans system is a good idea, but again, how it will be administered at the Independent University was not discussed in detail.

The final session was devoted to a discussion of the progress made so far by the planning board. Sir Sydney Cain said that the "project is increasingly in line with current thinking on university problems" and the board has been much heartened by the expressions of goodwill it has received. The chief task during the past few months has been to secure a site. Several are under consideration and one at Croydon has been investigated very thoroughly, in spite of "rather considerable" planning problems. Once a site has been secured, Sir Sydney said, the Independent University will petition for a charter and it hopes to take about 400 students in its first year of operation—possibly 1973—and eventually to build up to a student population of 3,000.

Because nobody at the meeting really challenged the basic idea of the Independent University, much of the discussion tended to revolve around particular points. The upshot was that the ultimate viability of the institution was barely questioned and some of the chief criticisms that can be levelled were not brought up. The problem in attracting good staff,

for example, was mentioned only in passing, and the problem of building up a good science faculty with limited funds was not dealt with very convincingly. But the biggest assumption, although backed up by favourable results from a questionnaire answered by 117 sixth formers, was that bright students will be interested in the university in spite of the fact that they will have the chance to go to a traditional university with state support.

MATHEMATICS TEACHERS

The Vicious Circle

THE continuing crisis over the shortage of mathematics teachers has been brought back into the public eye by the *Second Report on the Shortage of Teachers of Mathematics*, published by the Institute of Mathematics and its Applications. The report emphasizes that the official definition of a "qualified" teacher, which includes any graduate who has completed a course of teacher training, allows those with arts degrees and no formal training in mathematics to teach the subject and to receive full graduate allowance in their salaries. There is thus no financial incentive for teachers to teach the subject in which they have been trained and, with a surplus of arts graduates, this works against the best interests of pupils taking all science courses. Although salary scales in which there are built-in subject differentials would probably prove impractical, the institute suggests much more flexibility could be provided by giving outstanding teachers of any subject the opportunity for rapid promotion and other incentives with which other professions recognize unusual ability.

The Institute of Mathematics and its Applications suggests that as many as 50 per cent of pupils in maintained secondary schools have mathematics teachers who themselves lack even O-level qualifications in the subject. Although that is probably an exaggeration, the overall picture is now sufficiently clear—unless action is taken soon, the vicious circle whereby pupils are so put off mathematics by bad teaching that the proportion taking the subject (and hence the eventual proportion of mathematicians in succeeding generations of teachers) is falling drastically every year will become unbreakable. The Department of Education and Science had no comment to make on the detailed evidence put forward in the report. A DES spokesman was only prepared to say that the situation has been known for a long time, and the department has nothing to add.

CIVIL RIGHTS

Sakharov Again

by our Soviet Correspondent

ANDREI D. SAKHAROV, the Soviet nuclear physicist, is again at the centre of a controversy in the Soviet Union. Together with his fellow physicists Tverdokhlebov and Khalidze, he is proposing to set up a committee for the defence of human rights. Although such a committee, if registered with the state, would in theory be legal, it would be an embarrassment to the Soviet authorities to have a watchdog body to safeguard the rights of man, and in particular intellectual freedom, operating within the Soviet Union. To sanction the setting up of such a committee would be a tacit admission on the part of the Soviet authorities that it is needed.

Sakharov's proposed committee would lie within the bounds of Soviet law because the Soviet Union was a signatory to the Universal Declaration of Human Rights in 1948. But although the Soviet press reported the signing, the text of the declaration has never been published in the Union. The committee, its supporters maintain, is non-political and will not associate itself with any organization which is in any way anti-Soviet. In previous manifestos, Dr Sakharov has always denounced arbitrary and illegal behaviour towards individuals as being typical of the Stalin regime and he has urged that all such action should be stamped out as unwelcome inheritance from the past.

The formation of this committee will in many ways be a culmination of Dr Sakharov's previous efforts to establish a more liberal atmosphere in the Soviet Union. He published in 1968 an open letter, "Thoughts on Progress, Peaceful Coexistence and Intellectual Free-

BA under Scrutiny

THE British Association for the Advancement of Science has set up a committee to scrutinize and reinterpret the association's objectives and to review its future activities, finances and management. The setting up of such a committee was proposed at the British Association's annual meeting last September (see *Nature*, **227**, 1074; 1970), and its chairman will be the association's president, Sir Alexander Cairncross, master of St Peter's College, Oxford. Other members will be Sir Vivian Fuchs, the president elect and director of the British Antarctic Survey, Dame Kathleen Lonsdale, Sir Eric Mensforth, chairman of the Council of Engineering Institutions and general treasurer of the association, Dr H. M. Finniston, deputy chairman of the British Steel Corporation, Professor G. E. Fogg, professor of botany at Westfield College, London, Dr A. H. Hughes, managing director of Arthur Guinness Son & Co. Ltd, Lord Rennell of Rod, Sir David Martin, Dr J. D. Carthy, scientific director of the Fields Study Council, and Mr P. W. B. Semmens, products works technical manager of the ICI Agricultural Division.

The committee will be responsible for reviewing the economy of the association and it will seek new sources of finance and new means of co-operating with other scientific organizations with similar and overlapping interests. As for the association's task of considering the impact of science and technology on the quality of life of the community, the committee will enlist the further support of scientists and technologists and the goodwill of the press, radio and television. The committee will submit its findings to the council of the association in time for the annual meeting which is to be held at Swansea next September.

dom", which included an attack on the "crippling censorship" in the Soviet Union, and a demand for greater intellectual freedom. This was followed in March 1969 by an open letter to Brezhnev, Podgorni and Kosygin which suggested that intellectual repression can only act to the detriment of the state by hampering the whole process of economic growth and development. In particular, he pointed out that brainpower is wasted by the imprisonment or internment in mental hospitals of intellectuals for opposition "in the field of ideas and convictions" (see *Nature*, **226**, 210; 1970).

When Zhores Medvedev was arrested and taken to Kaluga mental hospital for just such "opposition", Dr Sakharov again wrote to Brezhnev. This letter was not only a reasoned plea for the release of the geneticist but virtually a manifesto of human rights as well.

COMPUTERS

Privacy and the Computer

THE British Computer Society has strongly criticized the approach of the Parliamentary Committee on Privacy to the problem of safeguarding the public against the computer. In a letter to the chairman of the committee, Mr A. Agapeyeff, president of the society, points out inadequacies in the committee's approach and suggests forms of legislation urgently required to prevent encroachment on privacy by the abuse of computerized personal data. He also says that the committee seems to be ignoring the dangers involved in using computers in public spheres.

Mr Agapeyeff points out that as computer systems become more complex, privacy is threatened not only from deliberate abuse of computer records of personal details but also from accidents in the programming and processing of the data. There are already too many victims of faulty bills, financial statements, automatic reminders and threats of legal action sent out by haywire computers and the situation is getting steadily worse. Moreover, Mr Agapeyeff suggests that public safety is at stake for the same reason. Computers are already deeply involved in monitoring, for example, nuclear power stations and military systems and before long they will also assist in air traffic control and in hospitals for monitoring intensive patient care. That there is no system for maintaining the standards of computing, says the society, represents a serious omission on the part of the computing industry.

Mr Agapeyeff proposes that there should be safeguards to protect the public from inexperienced computer operators and that computers should be checked by independent specialists before they are put into service. There should also be stricter systems for updating and "forgetting" incorrect data.

As far as intentional indiscriminate use of computerized personal data is concerned, Mr Agapeyeff suggests that the need for legislative control is obvious. Under economic pressure, the records have already become centralized and easily accessible and there are increasing incentives to market information to employers, customers and voters. The letter distinguishes between information that is inherently private such as medical and criminal records, and the semi- and potentially private information such as political affiliations and details of travel and companions. It goes on to suggest that in order to keep an eye on computers intending to process inherently private information, a system of licensing should be introduced and records should be kept of the type of data, its source, use and distribution. It should also be illegal for computer operators to reveal information to unauthorized third parties.

Whatever its fears, the society remains resolute in its belief that extensive computer applications are strongly in the national interest. The machine, says Mr Agapeyeff is morally neutral and it is up to the computer professionals to detect and alleviate the growing dangers which arise from faulty computing systems.

FOWL PEST

Epidemic Loses Momentum

THE fowl pest epidemic which has been afflicting British poultry for almost three months may have passed its peak, but it seems, nevertheless, to be trailing fresh hazards in its wake. Although it is not uncommon for poultry workers to contract a mild form of conjunctivitis—inflammation of the membranes around the eyes—following exposure to fowl pest virus (*Myxovirus multiforme*), a speaker at a recent meeting of the British Veterinary Association (BVA) warned that human response to the strain of virus causing the present epidemic is unusually severe. The symptoms include a fever resembling influenza, conjunctivitis, swollen glands and a variety of vague aches and pains. The BVA was swift to emphasize, however, that the virus can be contracted only by contact with live infected poultry, and that the disease in humans is not serious.

The present epidemic, hopefully, seems to be on the downswing. Outbreaks recorded up to last weekend totalled 1,690 and the number of fresh outbreaks is decreasing daily. Well over 4,000,000 birds have died since the epidemic began, mainly in East Anglia, but outbreaks have been reported in 38 counties in England with isolated cases in Scotland and Wales.

The epidemic seems largely to have been the result of complacency amongst poultry breeders. Over the past few years the incidence of Newcastle disease has been so slight that many breeders were lulled into a false sense of security and neglected to maintain full and regular vaccination and more than half the national poultry stock was not protected when the virus struck. As a result, the disease has ravaged disastrously through the unprotected stock, whereas vaccinated poultry has remained comparatively untouched.

Poultry vaccines used in this country are of the inactivated type, killed by treatment with formaldehyde or irradiation. In most other countries where poultry are reared intensively, live vaccine is used. This makes mass inoculation considerably simpler, even though the immunity conferred by this method has not always proved reliable. The Ministry of Agriculture has taken advantage of the present epidemic to test the live vaccine in the field. Trials are being carried out in specially chosen infected areas of East Anglia under close ministry supervision, but it is too early yet for the results to be assessed.

Poultry breeders are angry that the ministry did not use the live vaccine earlier in an effort to crush the epidemic in its initial stages; a more telling criticism is that it did not take a strong enough line with the poultrymen in the first place to ensure that a high standard of vaccination was maintained.

ATOMIC ENERGY

Construction Costs Soar

THE Central Electricity Generating Board has adopted a new strategy for the construction of its latest nuclear power station, Sizewell "B", by splitting up the contract so that the nuclear components will be tendered for separately from the generators and the civil engineering work. This practice of splitting up contracts has been common for conventional stations, but has never been applied to nuclear plant.

The CEGB has awarded the design contract for the 2,500 MW Sizewell B station to the Nuclear Power Group, one of the two British design and construction consortia, and it seems certain that the NPG will be given a firm contract next year for the construction of the nuclear islands, estimated to be worth about £140 million.

Sizewell B will be the largest nuclear power station in Britain when the last of its four reactors goes critical in 1977. The total cost is expected to be about £250 million which marks a considerable increase in capital cost per kilowatt since the Hinkley Point B station, also an advanced gas cooled reactor system, was started in 1967. Hinkley Point B cost about £76 a kilowatt whereas expenditure on Sizewell B is expected to reach about £100 a kilowatt. The CEGB points out, however, that the costs have still to be finalized.

UNIVERSITIES

Selection Procedures Condemned

A STINGING attack on the system of entry to British universities was delivered last week by the National Association of Careers Teachers. In a letter sent to the Committee of Vice-chancellors and to other bodies responsible for university admissions, the association points to many faults in the workings of the Universities Central Council on Admissions, and it is particularly scathing about the lack of liaison between universities and schools. There is rivalry between universities, faculties and departments, the association suggests, "and in consequence heads and careers teachers receive little help from these sources which may be used as a basis for reports on applicants from their schools".

The accusations are based on a recent survey of university applications carried out by the association. The letter points out, for example, that the apparent choice of five universities offered by the UCCA is a choice "on paper only". "It is patently obvious," says the association, "that for popular courses such as law, medicine and languages, those universities placed fourth and fifth rarely give serious consideration if any at all to the applicants concerned".

What is to be done? The association suggests that one of the more obvious drawbacks in the present selection system is that the universities select students before their A-level results are announced, and this results in undue complication. There is therefore a good case for reviewing the whole system of university selection, adjusting examination times so that the results are published by the end of July and moving the start of the first year of university courses to November. Alternatively, the association suggests, a student could be compelled to break off his studies for one year between A levels and university.

Parliament in Britain

Transfer of Research Establishments

RESPONSIBILITY for the Water Pollution Research Laboratory, the Hydraulic Research Station, the Forest Products Research Station and the Fire Research Station will be transferred from the Department of Trade and Industry to the Department for the Environment on January 1, 1971. Announcing this transfer, Mr David Howell, Parliamentary Secretary to the Civil Service Department, said that the functions of these laboratories fall chiefly within the ambit of the new Department for the Environment. By the same token, the Department for the Environment will take over the responsibility for administering grants to the Water Research Association and to the Construction Industry Research and Information Association. All these responsibilities were previously assumed by the Ministry of Technology. (Written answers, November 10.)

Research and Development Estimates

THE government intends to spend about £63 million on research and development in its own establishments in 1970–71. This figure includes expenditure on the Atomic Energy Authority, and it is about the same as the estimated total expenditure in 1968–69 and 1969–70. This announcement was made by Mr Nicholas Ridley, Under Secretary of State, Department of Trade and Industry, in reply to a question from Mr J. H. Osborn. (Written answers, November 9.)

British Steel Corporation

MR JOHN DAVIES, Secretary of State for Trade and Industry, hinted in a reply to Mr Gregor Mackenzie that the government is considering making changes in the structure of the British steel industry. He said that he is engaged in discussions with the British Steel Corporation to try to develop a structure for the industry which will assure it of a prosperous and satisfactory future. He also said that it would not be correct to assume that the management of the industry believes that it should be left exactly as it is. (Oral answers, November 9.)

National Health Service

SIR KEITH JOSEPH, Secretary of State for Social Services, gave details of how the government plans to spend the English share of the extra £110 million which will be made available to the social services over the next four years. A large share of the money will be spent on provision for the mentally handicapped and on improvement of hospital and local authority services for old people and the mentally ill. Each of these services will receive £40 million from the £110 million.

The Secretary of State also said that he hopes to make a statement soon about family planning, and about improvements in the accident and emergency services. A review of what should be done in these areas, he said, is under way. £3 million will also be set aside over the next four years for special units for the chronic sick, and an extra £2 million to improve facilities and advice for alcoholics.

The total resources available for the hospital, local authority and welfare services for 1971–72 will be about £5 million more than during the present financial year. This is an increase of 6 per cent, compared with an increase of 4·3 per cent during 1969–70. (Statement, November 11.)

Rolls-Royce Looks Happier

THE instability of the economic tightrope which Rolls-Royce has been obliged to walk almost since the start of development of the very successful Spey engines in the early 1960s has been highlighted during the past week. Rolls-Royce has announced a loss of £48 million during the first six months of this financial year, compared with a profit of £2·5 million last year, and the government has stepped in with massive additional launching aid of £42 million for the RB 211 turbofan engine. This aid will be supplemented by bank loans of £18 million and repaid by a levy on sales. Sighs of relief from both sides of the Atlantic that Britain's only aero engine manufacturer has been saved from financial disaster have shown how important Rolls-Royce is in the complex international aerospace web.

The firm's trouble is rooted in the ever escalating costs of the development of the "Dash 22" version of the RB 211 which is to be used in the Lockheed TriStar airbus. The engine contract was plucked from the hands of American competitors in 1968, but the penalty of landing such a prestigious order was a fixed quotation which required more than the average amount of guesswork. As it turned out, estimates for the total development cost have soared from £65 million in 1968 to £135 million at 1970 prices, and launching aid of £47 million granted by the government in 1968 is now seen to be entirely inadequate. A measure of the immediate seriousness of the situation is the provision by Rolls-Royce in its accounts of £45 million to offset the predicted loss on the 600 engines to be sold to Lockheed during the next five years.

The Rolls-Royce problem is essentially one of cash shortage, the source of which can be traced back to a change of accounting procedure in the early days of the Spey engine. At that time it became impossible to write off research and development totally against profits without depleting the latter to such an extent that the problems of raising further capital in the money market would become insuperable—about £90 million has been raised by loans and share issues in the last four years alone. The problem was solved by the expedient of charging only a proportion of research and development against profit and entering the remainder as a capital item in the balance sheet, to be written off as profits increased during production. The result was a healthy looking increase in profits from year to year but a hidden strain on cash resources which eventually forced the recent injection of £60 million.

The Industrial Reorganization Corporation (IRC) made a general loan of £10 million to Rolls-Royce earlier this year and several new directors were appointed, including Mr Ian Morrow, who now heads the new four man executive committee. It was Mr Morrow's probings and the financial monitoring by the IRC which revealed the company's critical financial situation and gave the government much of the factual information necessary for assessing the aid to be given. Ironically the IRC will be wound up at a time when its usefulness has been highlighted; it would have been the ideal body to watch over the now considerable public investment in Rolls-Royce, and to assess any future requirements for public money which might arise.

In some ways, Rolls-Royce has been shown to suffer from its own tradition of excellence. For example, some 2,000 new parts used to be produced each year as optional extras for existing designs of engine. The IRC investigations revealed too much self confidence and often a refusal to face the economic facts of life. The Rolls-Royce management was, for example, considering a draft contract with Lockheed which specifically promised carbon fibre reinforced fan blades and it was only at the insistence of Lockheed that a back-up programme of research into titanium blades was started. In the event the break-up of carbon fibre blades under adverse conditions, such as heavy rainstorms, made the titanium research vital, even though the extra weight of titanium blades in turn made other design changes necessary.

The Rolls-Royce situation will certainly have a bearing on the choice which the government has to make soon between the European airbus (the A300B) and the British Aircraft Corporation BAC 3-11, both of which are contenders for government support. If the government chose the BAC 3-11 it would saddle itself with two large items of expenditure: £75 million towards the development of the airframe and about £60 million for the development of the RB 211-61, an improved and lighter version of the "Dash 22". Even the offer of up to £50 million from the West German Government does not necessarily make the A300B project more attractive. General Electric, with one foot already in the door, is likely to win a considerable proportion of the engine orders for the United States, thus denying Rolls-Royce the long uninterrupted production run so badly needed and offered by the BAC 3-11 with its estimated sales of at least 280 aircraft (*Nature*, **228**, 496; 1970.)

The plain fact is that a single private firm does not have the boundless capital resources seemingly needed to support the research and development functions necessary in the aerospace industry, or the resilience to survive unaided the inevitable setbacks. It can be argued that Rolls-Royce channels too little of its effort (about 20 per cent) into bread-and-butter products such as marine engines, but although the non-aero side of the business is expanding well, it could never provide the degree of cushioning required. The continuing injection of government money and the appointment of watchdog directors are probably too close to nationalization to be contemplated by the government, although the aerospace industry in the United States is subsidized extensively and successfully in the guise of defence grants.

It has been suggested that the next logical step would be the formation of a European company with Rolls-Royce as its nucleus and comprising firms like the French SNECMA and Turbomeca and the West German group Motoren und Turbinen Union which are all intimately involved with Rolls-Royce in one or other of the joint ventures.

European Space Research in the Melting Pot

THE role to be played by Europe in space will probably be decided within the next two months. Following the abortive second session of the European Space Conference (ESC) which met in Brussels recently to consider NASA's proposals for a European share in the post-Apollo programme (see *Nature*, **228**, 596; 1970), the next planned step is the report now being prepared by a joint group from ELDO and ESRO on the feasibility of the shuttle proposals put forward by NASA. Moreover, the German delegation to the ESC, supported by the Belgian and French delegations, suggested that the deadline by which interested countries must decide which proposals they are prepared to support (if any) should be December 31.

Like the Concorde project, the question of cooperation in space research is subject to political as well as economic factors. West Germany is particularly enthusiastic about working with NASA on the next generation of spacecraft, while France and Belgium support the idea with some reservations. Britain has refused to make any commitment without a more well-defined proposal from NASA, which at present wants the ESC to commit itself to something like a 10 per cent share in the still undefined cost of a project. Italy, Holland, Sweden and Norway are, like Britain, interested in the proposal but refuse to commit themselves without more information. Denmark is not interested in participating in any post-Apollo programme, and is also withdrawing from ESRO.

On their own, the three firm supporters of participation in NASA's programme could supply only about 8 per cent of the total cost, and would therefore be in a very weak bargaining position when high level policy decisions are made. With the four more reluctant members of the ESC joining in, Europe might be able to provide a sufficient stake in the project for its voice to carry some weight at policy making levels. But even in the United States there is no consensus in favour of the shuttle and there is a possibility that if a majority of the European countries are against participating, the US Congress could be sufficiently influenced to cut back its space budget still further—as yet, no endorsement of any post-Apollo manned space flight programme has been given.

A major source of the present confusion is the differing interpretations placed on NASA's offer to launch satellites for European countries provided that they join the space shuttle programme. Some have interpreted this as implying that NASA will not provide launch facilities for those who do not help with the shuttle; the British view is that American launch facilities will still be available on a basis similar to the arrangements under which the Skynet and Ariel satellites have been launched for Britain by NASA. This is also the reason for Britain's split with Germany and France over the development of the Europa 3 launcher and which caused the British withdrawal from ELDO. On the basis of three failures to send into orbit a European satellite, and Britain's own unhappy record with Black Arrow, the argument that Europe should concentrate on satellite development and leave launch facilities to the Americans is very strong. There is no question that the British Ariel satellites have contributed greatly to scientific knowledge (see page 700), and there are now financial rewards such as the recent contract between the Hughes Aircraft Corporation and the British Aircraft Corporation.

Already the largest supplier of satellites and components in Europe, BAC now has an order book worth roughly $10 million, the recent contract with Hughes for components for the second generation of Intelsat 4 satellites accounting for one tenth of this total. BAC is also a partner in European aerospace consortia, and an interesting situation could arise if the countries in which their partners are based officially join the post-Apollo programme while Britain does not. In spite of the possibility of some political backlash affecting BAC, it would still have a good chance of playing a major role in the development of Europe's share of the programme. Commercially, a continued European space effort on Europa 3 and applications satellites plus a share in the American space effort is the most attractive prospect, but in the face of any extravagant speculation it is salutary to remember that the highly successful Skylark sounding rocket has been both BAC's greatest single money earner in the field of space research and has also provided a wealth of scientific data for relatively little cost.

The political situation is, as ever, extremely complex. Non-cooperation by Britain could be used in Europe as a barrier to the application to join the Common Market, while at the other extreme, complete European participation in the shuttle project might be viewed with alarm in the Pentagon by those who are impressed by the military applications of the new spacecraft.

The future for a cooperative European space effort therefore looks extremely gloomy. Even the proposed merging of ELDO and ESRO to form a European Space Organization dealing with both launchers and satellites seems to be merely an administrative shuffle. But there are two points yet to be decided which could even now result in a combined European partnership working at a high level (rather than merely as glorified sub-contractors) on the next stage of the US space programme. Mr Frederick Corfield, the Minister of Aviation Supply, has made it clear that Britain is quite prepared to examine any concrete proposals made by NASA, and he is at present simply refusing to sign a blank cheque with little say in what the money is spent on.

If any progress in this direction is made, the Swiss have offered to act as hosts to the next meeting of the ESC, and this could make for a more coherent conference than the recent shambles in Brussels, which arose partly because the chairman (traditionally provided by the host country) was an outspoken supporter of the acceptance in full of NASA's proposals, and did not provide the relative degree of impartiality appropriate for his position. The exact position here is far from clear because technically the last meeting of the ESC was adjourned unfinished, and traditionally it should therefore reconvene in the same country.

NEW WORLD

Gas and Germ Warfare Renounced but Lingers On

by our Washington Correspondent

A YEAR ago, on November 25, 1969, President Nixon renounced the first use of chemical or biological weapons by the United States. He said he would submit the Geneva Protocol of 1925 to the Senate for ratification, declared that the United States would confine its biological research to defensive measures and announced that preparations would be made to destroy existing stocks of bacteriological weapons. Lack of evident progress towards these goals in the last twelve months suggests that, like King Richard II, the President is finding the enactment of his dramatic renunciation harder than the recital of it.

The Geneva Protocol, which prohibits the first use in war of gases and bacteriological agents, was not submitted to the Senate until nine months after the President's speech. Further delay has been caused by the reluctance of Administration witnesses to appear before the Senate Foreign Relations Committee, which will now probably be unable to start its hearings on the Protocol until the new Congress meets next year.

Progress has been equally slow on the plans for destroying the present stockpiles of biological weapons. The consensus of two recent accounts*, widely regarded as accurate, is that the biological warfare arsenal at Pine Bluff, Arkansas, still includes stocks of the agents causing tularaemia, Q fever, anthrax and Venezuelan equine encephalitis. There are anti-crop agents causing diseases such as rice blast and wheat rust, and an arsenal of bullets and darts loaded with botulinum toxin. Unlike the deteriorating nerve gas rockets that gave the Army such a disposal problem two months ago, these agents are not, as far as is known, encased in concrete coffins along with explosives. Proteins being denaturable by heat, it would seem that a procedure not greatly more complicated than boiling would suffice to destroy the contents of Pine Bluff. But twelve months after the President's statement, the stockpiles are still there.

So too is Fort Detrick, the Army's chief biological research centre, which was to have been handed over for peaceful uses to the National Institutes of Health. The transfer, approved by government officials at one level, seems now to have been vetoed at another.

Dissension is also apparent within the Administration on the question of classified biological research. At a background briefing in February a "high White House official" seems to have stated that classified research in biological warfare would henceforth be unnecessary. This position has been frankly repudiated by the Army, which makes little effort to deny that it is still conducting classified research and expects to continue doing so. The military view is that certain of the defensive research sanctioned in the President's statement "raises requirements that some of our biological research would have to be classified", an Army spokesman said last week.

The general absence of forward movement in the direction pointed by President Nixon is ascribed by some to skilful delaying tactics by the Army, which is held to be determined not to drop its biological weapons until its hand is forced. In the most open aspect of these affairs, the ratification of the Geneva Protocol, the Administration appears to have given little leadership to those pursuing the new policies it initiated, and it could be that in the more covert ramifications of his decision as well, the President is meeting a certain amount of inertia. But whatever obstructions the Pentagon may have placed in the path of the renunciation of biological weapons, there are less devious reasons for at least some part of the delay.

Destruction of the stockpiles, for example, is not the Army's sole responsibility but must be agreed as to method with the Surgeon-General's Office in the Department of Health, Education and Welfare, with the Office of Science and Technology and with the Department of Agriculture. There have clearly been problems in getting the several agencies to agree on a visibly safe method for disposing of the stockpiles. The interagency coordination is still not yet finished but agreement is now very close, a member of the Office of Science and Technology said last week. "The plan has not yet been finalized but we know pretty much how it is to be done."

On the vexed issue of classified research the same official did not deny that some secret research would go on, but stressed that it would be kept to a minimum. "I'm sure if we do have any classified biological research it will be only if it is judged absolutely necessary to protect the national security," he said. This position seems the likely compromise to the present dispute now going on within the Administration between those who argue that defensive research on matters such as immunization procedures can be conducted openly and those who hold that secret research is necessary. Proponents of classified work see the need to develop offensive strains of microorganisms—research which it is generally agreed should be classified—in order both to develop protection against them and to analyse strains gathered abroad by intelligence agencies.

Another sign of the Army's reluctance to follow President Nixon's directive is said to be the $23·2 million requested for biological warfare research in the present financial year, which in fact exceeds the $21·9 million spent last year. Army spokesmen reply that the budget request for the present financial year—which Congress has already reduced to an authorized maximum of $21·1 million and may cut still further in the appropriation process—was made before the President's November 25 speech. The budget request for 1971–72 is in fact as low as $10 million, a more than 50 per cent reduction. Administration officials explain that this year's authorization for biological warfare research is nearly as large as last year's expenditure because of the heavy costs incurred in winding up installations and paying termination benefits to staff.

Financial rather than political reasons may also underlie in part the apparent failure of the National Institutes of Health to capture the nearby Fort Detrick. The NIH has proposed to convert the unique facilities

* Seymour M. Hersh, *Washington Post*, 20.x.70; Robert M. Smith, *New York Times*, 10.xi.70.

of the centre to research on slow and hot virus diseases. The proposals would have provided employment for 700 scientists and technicians (some of whom could have been supplied from the present staff of Fort Detrick) with annual running costs of $15 million. Several organizations put in bids to take Fort Detrick off the Army's hands; "Ours," said an NIH official last week, "was considered especially propitious by higher echelons (of the Administration), but they weren't high enough." Although no final decision is known to have been made, it seems that a memorandum has been sent from the Office of Management and Budget to the Secretary of Health, Education and Welfare to the effect that the NIH proposal for Fort Detrick's future is too expensive.

Does the Administration's tolerance of these various impediments and delays betoken a shift of position on biological warfare, or merely preoccupation with larger issues? Apart from the troubles facing the official interpretation of the Geneva Protocol—President Nixon seems not to have been properly briefed on the extent of the likely opposition—the factors behind the renunciation appear not to have changed. The decision was certainly helped along by accidents such as the 6,000 sheep gassed at Dugway in March 1968, but it rested substantially on an Administration review of current programmes in biological warfare research. The review, the first for fifteen years, is said to have appalled many officials by the direction that the research was taking. Papers were presented giving the President his options and he made his choice. Unfortunately, in one point of view, the issue of using tear gas and herbicides in war was considered in conjunction with the bacteriological and other forms of biological warfare. The military as well as legal grounds for using these two types of agent in Vietnam are not particularly strong and had they been judged on their own merits the decision might have been to drop them. Considered along with other biological agents there was a natural pressure towards compromise, the terms of which could have been that bacteriological agents would be dropped in return for reservations to the Geneva Protocol regarding incapacitating gases and herbicides.

Thus or otherwise, in the letter transmitting the Geneva Protocol to the Senate Secretary of State William P. Rogers gave it as his understanding that the Protocol does not cover incapacitating gases and herbicides. The Senate Foreign Relations Committee has not yet been able to hold hearings on the Protocol —the earliest date the Secretary of State and Joint Chiefs of Staff, the customary first witnesses, can offer is mid-December—and the Protocol will probably not be reported to the floor of the Senate until early next year. There it seems set for a bruising debate. Senator Nelson has already introduced a contrary understanding to the effect that the Protocol does prohibit the use of chemical herbicides in war. In as far as this is just a legal issue, the Senate is likely to be influenced by the clear-cut 80 to 3 vote by which the United Nations last December asserted that tear gas and herbicides are covered by the treaty. The debate seems certain to bring up the divisive issues of the Vietnam war, although there could be some kind of coalition between hawkish Senators concerned with the effect of the reservations on arms control and those with doveish positions on Vietnam and the use of herbicides there.

President Nixon has not publicly committed himself to an interpretation of the Geneva Protocol and it looks as if the Secretary of State's letter of transmittal represents the Administration's final word, beyond which the matter is to lie in the lap of the Senate. Opponents of chemical and biological warfare take comfort in the fact that the statement of the Administration's views in the form of an "understanding" is less entrenched a position than a declaration or formal reservation would have been. But a formal reservation could force other signatories of the treaty to agree with or dissent from the US position, whereas an "understanding" presents a sufficiently low profile to be overlooked.

CANADA

Science Council Reveals All

by our Physical Science Editor

A THOUGHTFUL open letter has been written to the Canadian physics community in the shape of the Canadian Association of Physicists by the Science Council of Canada, and is published in this month's edition of the association's journal *Physics in Canada*. What the letter boils down to is that there will have to be some heart-searching among scientists in Canada, and the greater the number of people who take part in the debate the better the chances of everybody being happy with the results.

Canada, of course, is well known to be among the most introspective of nations when it comes to the management of science, yet for all the talk Canadian science is only in average shape. The chief reason is that expenditure on science is not rising at anything like the rate that people were hoping only a year or two ago. The target date for the attainment of an R&D expenditure running at the comparatively modest level of 2 per cent of the GNP is receding like a mirage. Last year the Science Council was recommending that 1973 be the target; now it seems unlikely to be reached even by 1975.

What this means is that belts will have to remain tightened, especially in what are called the basic sciences. It is now fairly well recognized that the more serious problems afflicting Canadian science are in what has become a no-man's-land between university and industrial research. With these problems in mind, the Science Council has decided to lay its cards on the table, setting out its views in an open letter to the physicists rather than in a formal report. The reasonable hope is that this will better stimulate the physics community to express its reactions. The letter ranges over all aspects of science funding where physicists are involved, and provides some new information about the standing of the Science Council on some particular questions. In Canada as everywhere else the support that should be given to what is called big science is the most hotly debated, and the open letter raises some questions which up to now have frequently been swept under the carpet. "The existence of a single big science project will determine the interests of the participating scientists, often for a decade or longer. The problem is potentially much more significant in the case of a scientific discipline which has invested a large share of its total resources in big science. Are big science projects self-perpetuating? Do the participants have many real options for significantly changing the course of their discipline?" Later in the letter the Science Council asks whether investment in high energy physics would be a godsend or a millstone for

Canadian physics. Big science projects generate a momentum of their own.

Debate along these lines has already weighed heavily in the Science Council's decision that it would be better for Canada that money be spent on a 50 per cent share of the Carnegie Institution's project for a 200-inch optical telescope in Chile than in buying a share in the 200 GeV accelerator at Batavia. (Since that decision was taken, however, a question mark must have arisen over the Carnegie project following the change of government in Chile.)

The reasons for not supporting the Batavia project are set out for the first time in the letter. In the words of the Science Council, the high energy physics group in Canada is "small, competent, well-coordinated and, in contrast to the astronomers, is thoroughly cohesive with no sign of internal stresses and strains", but the decision went against them because this is a field of limited interest, the investment would probably not guarantee a proportional share of time on the machine, and there is even less money to be made in high energy physics than in astronomy. In passing, the council mentions that it is still unhappy with the way that astronomy is being run in Canada; in particular the council is disturbed that the desirable coordination of Canadian astronomy, which was to have taken place under the NRC, has not yet materialized.

In the course of its discussion of the worth of big science, the council also has some home truths to tell about the desirability of internationally shared facilities. "The international nature of a proposed venture is not," the council bluntly states, "a strong selling point." That is something to be taken account of in Europe, where pressure for more international projects is to be expected on political grounds. International ventures, the council says, are hard to assess, slow in gaining approval, are not usually productive unless there is a strong home base, and lead to minority partners being dependent on the good graces of the major partner and to uncertainties about the distribution of any profits that may accrue.

Much of the remainder of the letter is rightly taken up with a discussion of how to break down the barriers between what the letter calls the four solitudes in Canada—government, industry, university and the financial community. The best way to let in the fresh air the council suggests is to have some major national programmes that would cut across the boundaries. But there are things that can be done even before these rallying calls are sounded:

- Government departments and agencies should contract out more of their R&D to the universities and industry.
- The government should use its purchasing powers to encourage innovation and better design.
- Individual scientists in government, industry and the universities should try to become aware of each other's problems. There should be applied institutes attached to the universities, and industry could subcontract some of its research work to the universities.
- There should be more support for postdoctoral fellows to work in industry and for industrial scientists to spend sabbaticals in the universities.

What part does the Science Council of Canada itself want to play in all this? The letter suggests that the council should act as arbiter between competing claims on the funds. Only when a new area of science arises with nobody to speak for it should the council enter the fray as a participant. Usually normal competition between scientists for funds will automatically lead to the best use of resources, but it is possible for monopolies to develop. For this reason there needs to be assessment from outside. It is good that the Science Council considers that the scientific societies, such as the Canadian Association of Physicists, should play an active part in helping to decide where the money goes.

TECHNOLOGY

No Longer Glamour Industries

by our Cambridge Correspondent

In the last ten years a new species of industry has emerged. Its rise and fall are worth careful study by anyone at least marginally concerned with science and government.

Along Route 128, a frantic highway which gives Boston a wide berth, has grown up a large number of moderately sized businesses selling, in the main, computer software, electronic components and other instrumentation necessary to a transistorized military. The Boston environment, with Harvard, MIT and a small number of defence-oriented laboratories, was undoubtedly the reason this phenomenon flowered most extensively in Massachusetts. Indeed, many firms were founded by research scientists from these institutions who found their salary not commensurate with the value of the things they were discovering. A few have become household words. A Route 128 industry can immediately be spotted by its discreet facade among shrubs and trees. Everything carefully landscaped, no vulgar neon signs or anything which obtrudes on the passing driver's vision. The main asset of these industries has been their brain-power—they are rich in PhDs and computers and employ relatively few manual labourers. Nevertheless, between them they constitute a major ingredient of the military–industrial complex, solving space age problems and cornering a huge share of the Defense Department's research budget. Much civilian work is also done, but it is the sustenance of the military money which has really made things tick.

Suddenly Route 128 has found itself synonymous no longer with a swinging young industry but with chronic financial troubles and huge lay-offs. Layings-off are, of course, nothing unusual in the volatile aerospace industry, but this is something different in that it is whole research teams that are being broken up. The most recent figures suggest that something like 2,000 highly qualified engineers and scientists have recently become unemployed in Massachusetts. This excludes the preposterous mishandling a few months ago of the Cambridge NASA Electronics Center which involved the tearing down of a sizable part of Cambridge to produce hideous laboratories which were promptly declared redundant by NASA once staffing was well under way. All in all, it has been a very bad year for technology based industry.

Some glib political commentators of which Boston has a surfeit see Nixon taking revenge on the liberal Senators Kennedy and Brooke who have not been of much help to the President in the last two years. A much more reasonable explanation lies in the harsh economic fact of a tightly restrained defence budget in an inflationary period and the harsh technical fact of a lack of impetus in a lot of science today.

It was inevitable that with a relatively stationary defence budget a lot of suffering would befall the less monolithic parts of the military–industrial establishment and to this extent Route 128 industries have been very much the jam on the bread-and-butter. Government contracts simply have just not materialized, nor is there any good sign for the future. Ironically, many of the employees now being laid off would be counted amongst the liberals who believe defence spending should be held, ABM deployment deferred and so on. The first tightening of the belt had some salutary effects. Ten years of unbridled affluence had left many firms much too fat, and early reductions in staffing removed some of the portliness. One personnel officer not afflicted by these troubles noted that the first ten applicants for a computer programming post had all been laid off, all described themselves as programmers and yet had minimal skills in that subject, for which they appeared to have been paid extraordinarily well.

But now the dismissals are cutting right into the research teams and leaving many highly qualified scientists and engineers jobless. One of the less palatable but more plausible explanations for this rapidly ebbing tide is simply that some branches of science are coming up hard against the stops. There just does appear to be less to get excited about in aerospace and defence research. Systems are big, roles small and objectives for each group limited. A certain dynamic seems to be lacking and perhaps this is because of an awareness that there are no breakthroughs just around the corner. Scientists and engineers don't retain their identity long as small cogs in big wheels and this sort of environment may have stifled the ingenuity of many. Certainly a fairly common feature today is the unhappy scientist—even unhappy if earning $30,000 and not in danger of being laid off. It may well be that after ten years of intensive vocational training many PhDs find that the frontiers to which they have been remorsely led are not anything like as glittering and amenable to being pushed back as they had fondly imagined.

With too many men chasing too few jobs and insufficient intellectual challenge, colleges ought to have seen the writing on the wall. Colleges may have an important role to play in dissuading entrants from becoming highly proficient in fields where their expertise is no longer wanted. The wisdom, for instance, of colossal courses on solid state physics, atomic and nuclear physics and high energy physics as the staple diet of the complete physicist is increasingly being brought into question and the more articulate students are saying in increasing numbers that they resent the time spent in this work. There are even very vague rumblings amongst the activists against what they regard as the deceptive practice of professors teaching vocational courses without revealing the lack of job prospects. Exponential growth is clearly at an end.

DETERGENTS

Good News for Soap

from our New York Correspondent

A TOTAL ban on the sale of a whole class of detergents, the first in the United States, will go into effect in Suffolk County, Long Island, on March 1, 1971. The ban is directed against detergents containing alkyl-benzene sulphonates, alcohol sulphates, and all methylene blue active materials except those used in automatic dishwashers, shampoo and toothpaste.

The ban has not satisfied all ecologists, however, because it fails to discriminate against phosphates, contained in nearly all detergents, and held to blame for the eutrophication of lakes and rivers.

The alkyl-benzene sulphonates, or ABSs as they are known, have been banned in Suffolk County in essence because they are not degraded by micro-organisms in anaerobic conditions. Suffolk County has no sewer system and nine tenths of its sewage is treated in cesspools, which are anaerobic.

Although phosphates are the generally more pernicious ingredients in detergents, the ABSs have been causing a more obvious problem in Suffolk County for the past fifteen years, and the county Board of Health had warned that continued widespread use of detergents would seriously pollute the county's underground water supply. The problem is primarily an aesthetic one in that the ABSs cause foaming, discoloration, and bitterness when they are present in the drinking water.

Nearly two hundred brands of detergents will be affected by the new law. The Soap and Detergent Association, which estimates total detergent sales in the county at $6 million annually, claims that with only minimal sewage treatment, present detergents would be totally biodegradable and that much of the present problem in Suffolk is probably due to the continued presence of totally nonbiodegradable ABSs that were used in detergents up to 1957. The Association argues that the ban is attacking only the effect, not the cause, of the pollution problem. What is needed, it says, is sewage treatment. The Suffolk County Water Authority agrees that the county is twenty years behind the times in sewage treatment and that the new law is merely a stop-gap measure, but claims it is necessary nevertheless.

The first referendum to install sewers in the county was passed only last year. The $275 million project will cover the south-west section of the county, and will take ten to fifteen years to complete. In the meantime, the population is growing rapidly but developers and homeowners are still unwilling to install a vastly more expensive sewer system as long as cesspools are adequate for the job. And they probably will remain so for most of the county once detergents are no longer present to contaminate the public water supply.

Although Suffolk has taken a first step in its ban on detergent sales, this is unlikely to mean a permanent end to the use of detergents in the county. In spite of the Soap and Detergent Association's outcry against the ban, it seems likely that the detergent manufacturers will quickly overcome the problem by the simple expedient of eliminating the nonbiodegradable ingredients from their products. The ingredients are not essential to the basic cleaning function of the detergents and, since detergents are simply a mixture of ingredients, it would be a fairly simple task to merely leave out the questionable compounds, still solving Suffolk's immediate problem, but continuing the phosphate controversy.

It now appears, however, that New York City itself may take the next step next spring by banning the sale of phosphate-containing detergents. The Environmental Protection Administration is considering this possibility, a situation that the detergent manufacturers will find considerably harder to resolve.

NEWS AND VIEWS

Factor Saga Continues

FINDING factors which control the transcription of RNA continues apace, for on page 748 of this issue of *Nature*, Travers reports the discovery of another such protein, which in the Hellenophilic tradition of Harvard he duly names psi, succeeding the sigma and rho factors previously discovered there. Psi enables RNA polymerase to transcribe specifically the genes of *Escherichia coli* which code for ribosomal RNA. This is perhaps the most significant factor report yet, for it makes the whole jigsaw of hitherto unrelated observations on RNA synthesis fall into place to suggest parallel mechanisms for the central control of messenger and ribosomal RNA synthesis in bacteria.

A curious feature of the systems used to transcribe RNA *in vitro* is that no ribosomal RNA seems to be synthesized. But *in vivo*, although the cistrons coding for ribosomal RNA comprise only about 0·3 per cent of the genome, the synthesis of ribosomal RNA can account for up to forty per cent of total RNA synthesis. (This implies that the overall rate of synthesis per cistron must be much greater for ribosomal than for messenger RNA.)

The absence of ribosomal RNA synthesis in the *in vitro* systems, Travers argues, means that they must lack some factor(s) responsible for directing the polymerase to transcribe the rRNA cistrons *in vivo*. He reports that a crude ribosome-free extract of *E. coli* contains the expected activity, which stimulates the synthesis of rRNA *in vitro* at least a hundred-fold. Almost a third of the RNA synthesized in the presence of the psi extract is ribosomal (although there is also an equivalent increase in the synthesis of other, unidentified RNA species).

Synthesis of ribosomal RNA in *E. coli* cells may at first seem quite unrelated to the replication of RNA which takes place when the bacterial cell is infected with an RNA bacteriophage, but Travers shows that there is a close, if not intimate, relationship between these two processes. For some time there have been indications that they may be connected, because some RNA phages inhibit the synthesis of ribosomal RNA during their infectious cycle.

RNA phages are replicated by a special enzyme, RNA replicase, which is found only in the phage-infected cells. The replicase of phage Qβ is an interesting protein which, as Kamen and Kondo, Gallerani and Weissmann showed two weeks ago (*Nature*, **228**, 525 and 527; 1970), consists of four different polypeptides. Only one of these (molecular weight 65,000) is coded by the phage itself; the remaining three (molecular weights 75,000, 45,000 and 35,000) are coded by the host bacterium and must presumably associate with the phage-specified polypeptide after infection to create the replicase enzyme.

Travers was spared the tedium of isolating psi from the crude extract because of the finding that, when added to the *in vitro* transcribing system, the two smaller subunits of Qβ replicase exercise an activity functionally identical with that of the extract from *E. coli*. (Travers does not yet know whether either or both subunits comprise the active fraction.) This explains the relationship between ribosomal RNA synthesis and RNA phage replication, which presumably compete with one another for psi.

The advantage to the cell—in selective terms—of sharing psi between these two functions is obscure, at best, but promises to prove interesting. One possibility is that because phage Qβ contains only three or four genes, it cannot itself code for a sufficiently complex replicating enzyme, and has therefore had to resort to making use of bacterial polypeptides. If psi really is either or both of the Qβ replicase subunits, the mechanisms which it uses to participate both in the transcription of RNA from DNA and in the replication of RNA should prove a fruitful field for study.

What does psi do in uninfected bacterial cells? Although it controls the transcription of specific RNA species, it is not another sigma factor. Sigma was the first transcription factor found, when RNA polymerase was separated into its subunits; the core enzyme, consisting of four polypeptide chains, synthesizes the phosphodiester bonds of RNA, and the single polypeptide chain sigma restricts the core enzyme to initiating transcription at certain genes. Transcription of some bacteriophages during infection is controlled by production of successive phage-coded sigma-like factors which replace the host sigma and direct the host core enzyme to transcribe specific phage genes.

It is an open question whether the action of sigma is to bind to core enzyme and indirectly influence the promoters recognized, or whether it directly recognizes certain sequences in DNA. It is unlikely, however, that psi works by the latter mechanism; its apparent involvement with the Qβ replicase suggests that it probably recognizes proteins rather than nucleic acids.

There seems to be only one sigma factor in uninfected bacterial cells, and psi acts on the complete RNA polymerase, which consists of both core enzyme and sigma factor. This action is strongly reminiscent of

another recently found control factor. The lactose and other inducible operons of *E. coli* cannot be expressed completely unless cyclic AMP is present in the cell. The effect of the nucleotide is mediated by a protein factor (termed CAP), which seems to act on the initiation of transcription by RNA polymerase at the promoter of the operon. This factor too seems to act on the complete enzyme.

The similarity between psi and CAP also extends to their interaction with nucleotides. Although no one has suggested that psi interacts with the all pervasive cyclic AMP, Travers throws out a tantalizing hint that it may interact with ppGpp, a guanosine tetraphosphate. The implications of this interaction are exciting. In normal (stringent) *E. coli* cells, starvation for essential amino-acids blocks not only protein synthesis but also the synthesis of ribosomal and transfer RNA, although messenger RNA synthesis seems to continue. The effect is abolished in a (relaxed) mutant strain, in which all RNA synthesis continues irrespective of the state of protein synthesis. Comparison of normal *E. coli* with the mutant suggests that the effect is mediated by ppGpp, which accumulates in stringent cells starved for essential amino-acids.

Psi is a good candidate for the controlling protein which must mediate the effect of ppGpp on stable RNA synthesis. Just as CAP is a protein which when activated by cyclic AMP acts as a general control element which is required for the complete expression of many bacterial operons, psi may be a general control element which, unless inactivated by ppGpp, keeps RNA polymerase transcribing ribosomal RNA, and perhaps also transfer RNA genes. (The action of psi may also explain the greater overall rate of expression of ribosomal RNA genes.) This response to small molecules would allow bacteria independently to adjust the synthesis of different classes of RNA to any changes in the environment.

PROTEINS

Sequence Sequel

from our Molecular Biology Correspondent

FOLLOWING on Jörnvall's sequence of the 374 residues of liver alcohol dehydrogenase, about which I wrote a few weeks ago, comes another *tour de force* of protein chemistry. With five of his colleagues, E. L. Smith reports an all but complete sequence for bovine glutamate dehydrogenase (Smith *et al.*, *Proc. US Nat. Acad. Sci.*, **67**, 724; 1970). In its native state, at low concentration, this enzyme is a hexamer, which undergoes an indefinite concentration-dependent association to form long rods. The monomer has a considerably greater molecular weight than those of the other known NAD-dependent dehydrogenases: according to the new sequence there are 506 residues in the chain, and the corresponding weight of 56,000 agrees with physically measured values.

The sequence is regarded as tentative, because at two points overlap has not yet been achieved, and here and there a few residues have not been fully ordered. The first conclusion from this work is that, because the sequence is unique, the subunits are identical. Taken with the other known sequences for dehydrogenases of different quaternary structure, this seems to establish a clear pattern. There is some polarization of composition, with clusters of charged and hydrophobic residues at opposite ends of the chain. Since there is little perceptible homology of sequence between liver alcohol dehydrogenase and glyceraldehyde 3-phosphate dehydrogenase, which are much closer together in size, it is not surprising that a comparison, using a computer search, of the glutamate dehydrogenase sequence with that of the latter also shows scant similarity. A strange exception occurs at one point in the chain, however: a run of twelve residues—94 to 105 in glutamate dehydrogenase, and 209–220 in glyceraldehyde 3-phosphate dehydrogenase—are identical in six positions, and have conservative substitutions, with single-base mutations in the rest. Moreover, both proteins contain enzymatically essential lysines, and Smith *et al.* have identified the one in their enzyme by way of its interaction with pyridoxal phosphate. This reagent can be used as a covalent label, for reduction of the labile Schiff base adduct leaves it irreversibly bound. The vital residue turns out to be lys-97, which is in the conserved peptide sequence. Glyceraldehyde 3-phosphate dehydrogenase also contains a lysine in the corresponding position of this segment, but the only lysine known to be functionally vital was identified by Harris and Perham as residue 183. It is not obvious what one is to make of this fugitive hint of common gene ancestry.

Smith *et al.* have in addition identified what seems to be an activity-controlling ligand binding site. It is known that modification of one tyrosine residue leads to loss of response towards the non-competitive inhibitor, GTP. The tyrosine, labelled with a 3-nitro group, has been identified as residue 412.

It is worth noting that subunit enzymes with identical chains now seem to be very common. An interesting example is the enzyme, thiolase, in which thiols operate as acyl acceptors in catalysis. The molecular weight is 170,000, breaking down to 42,000 in a denaturing medium. Gehring and Harris (*Europ. J. Biochem.*, **16**, 487; 1970) have ascertained that there is only one N-terminal tripeptide sequence, and that the number of tryptic peptides corresponds to the known content of lysine and arginine, if there are four chains. It is reasonable to infer that the subunits are identical. The protein is inactivated by reaction with iodoacetamide at the level of one molecule per chain. In their second article (*ibid.*, 492) Gehring and Harris report how they isolated peptides from the protein so modified, and showed that the substituent is an o-thiol, which is in a unique sequence at least to the extent of twenty-six residues. It is the same thiol groups which are acetylated when fragments are prepared from the enzyme-substrate complex, and are therefore marked as the catalytic residues.

VIRUSES

Doing without Cells

from our Cell Biology Correspondent

FOR the past several years the ribonucleoprotein particles which contain vaccinia virus DNA, and

which can be found in the cytoplasm of cells infected with this virus, have usually been refered to as "DNA factories". They have now been rechristened in the Latin by Dahl and Kates (*Virology*, **42**, 453; 1970), who apparently believe that virosomes is a better name because it does not "create a misleading impression concerning their composition and function". Be that as it may, Dahl and Kates have succeeded in isolating these complexes from infected HeLa cells. The virosomes are heterogeneous in size and density and the various classes of virosomes are related by some complex precursor product relationship which has yet to be fully resolved. What is more interesting is that the dense virosomes isolated three hours after infection contain nearly all the newly replicated viral DNA and an endogenous RNA polymerase activity (Dahl and Kates, *ibid.*, 463). *In vitro* the isolated virosomes can synthesize RNA which competes in hybridization experiments with both "early" and "late" viral RNAs made *in vivo*.

To convince themselves of the reality of "early" and "late" viral RNAs in infected cells, Dahl and Kates transcribed *in vitro* purified viral DNA with RNA polymerase from *E. coli*. They then analysed the sequences present in RNA extracted from infected cells at early and late times by competition hybridization experiments with the RNA made *in vitro* by the bacterial enzyme. The RNA isolated from cells six hours after infection competed with about 97 per cent of the RNA made *in vitro*. By contrast the RNA extracted from cells 1·5 hours after infection only competed with about 40 per cent of the *in vitro* RNA. Apart from proving that sequences are present in "late" RNA which are not present in "early" RNA, this experiment indicates that *E. coli* RNA polymerase transcribes one and the same strand of vaccinia DNA as is transcribed in cells. Green and Westphal have respectively shown that *E. coli* polymerase asymmetrically transcribes the correct strand of adenovirus 2 and SV40 DNAs. Presumably the bacterial enzyme readily recognizes the promoter sequences in these viral DNAs, which hints that such sequences may be universally similar.

In the same issue of *Virology* (page 508), Bukrinskaya, Bykovsky and Zhdanov report that a ribonucleoprotein complex isolated from Sendai virus particles associates with ribosomes from Ehrlich ascites or chick embryo cells; and, in a suitable cell-free system, it stimulates a five-fold increase in the incorporation of leucine and phenylalanine. This stimulation is inhibited by puromycin, the omission of ATP or the S-100 fraction, and the extent of the incorporation depends on the amount of ribonucleoprotein complex added. Bukrinskaya *et al.* suggest, therefore, that they are detecting protein synthesis directed by Sendai RNA. They further claim that because the incubation mixture after thirty minutes contains an RNA polymerase activity, which is insensitive to actinomycin D, one of the proteins being made is viral RNA polymerase. A full report of these experiments will be awaited with interest.

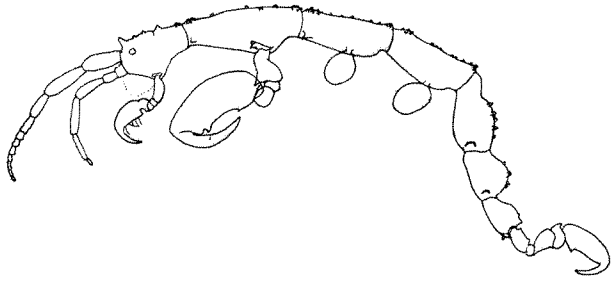
Jockusch, Bull and Kaesberg (*ibid.*, 401) report that an *E. coli* cell-free system programmed with bacteriophage Qβ RNA makes three of the four proteins which are found in extracts of infected *E. coli*. This result, therefore, leaves open the question of whether the Qβ genome contains four rather than three cistrons, as does the characterization of Qβ mutants reported by Horiuchi and Matsuhashi (*ibid.*, 49). They find that the twenty-two amber mutants which they have tested fit into only three complementation groups.

BACTERIOPHAGE

Heads and Tails

from our Cell Biology Correspondent

THE assembly *in vitro* of such macromolecular complexes as bacteriophage R17, tobacco mosaic virus and ribosomes of *E. coli* from purified preparations of nucleic acids and proteins leaves little doubt about the importance of self assembly mechanisms in the genesis of viruses and cell organelles. But such observations can belie the amount of genetic information which may be required for the synthesis of comparatively simple macromolecular structures, for work with the DNA bacteriophages, such as the T phages and lambda phage, indicates that the number of genes implicated in the morphogenesis of these phage particles far exceeds the number of genes which specify molecules actually found in the particles.



Bacteriophage lambda, for example, is by any standards a simple structure; each particle consists of a head, the phage DNA and associated internal proteins enclosed in a roughly spherical protein coat, and a tail, an aggregate of protein. It is perhaps surprising therefore that genetic analyses of the lambda chromosome have implicated at least eighteen genes in the production of heads and tails, especially since Siminovitch's group (*Virology*, **42**, 375, 390; 1970) have extended earlier work and proved that only three species of proteins account for at least 95 per cent of the total protein in each phage particle.

Buchwald, Steed-Glaister and Siminovitch, using two amber mutants, have isolated pure, empty heads which sediment at 114S and have a molecular weight of 18×10^6 and tails which sediment at 43S and have a molecular weight of $6{\cdot}1 \times 10^6$. These two components account for about 75 per cent of the protein in the phages. Buchwald, Murialdo and Siminovitch have analysed on SDS polyacrylamide gels the proteins of dissociated heads, tails and whole phage. The head protein has a molecular weight of 37,500, the tail protein has a molecular weight of 32,500; and a protein present in phage, but not in heads or tails, has a molecular weight of 11,000. These three proteins account for 57, 19 and 19 per cent respectively of the total phage protein. Minor protein components no doubt account for the other 4–5 per cent—three to six minor proteins can be detected by electrophoresing dissociated whole phage.

Genetic analyses reported by others and now confirmed by Buchwald *et al.* show that the head protein is coded by gene *E* while gene *V* specifies the tail protein. The gene which specifies the third major protein, that with a molecular weight of 11,000, has yet to be identified and the same is true of the genes which specify the minor protein components. If there are as many as six minor proteins specified by the phage, the roles of nine genes will be accounted for; but what do the other nine genes implicated in the morphogenesis of the phage do? Some at least may well specify proteins required for the assembly of the phage but not components of the particles. If that is the case it will be extremely difficult to define precisely the function of these putative proteins, but their existence should caution against over-emphasis of the role of molecular self assembly.

INVERTEBRATES

North Pacific Catch

This crustacean, *Caprella pustulata*, is one of six new species described, together with a new genus, *Pseudoliropus*, in an account of the Caprellidae of the American North Pacific (Laubitz, D. R., *Publications in Biological Oceanography* No. 1, National Museums of Canada; 1970). The animal shown here is a male *C. pustulata*, and it is 7·9 mm long.

RIBOSOMES

Phosphorylated for Storage

from our Nucleic Acids Correspondent

A STORAGE function has been suggested for ribosomes which are phosphorylated and apparently inactive. D. Khabat has made this suggestion after extensive investigations of the occurrence and properties of phosphorylated ribosomal proteins from rabbit reticulocytes (*Biochemistry*, **9**, 4160; 1970).

Ribosomes from this source have the particular advantage that the phosphorylation of the proteins can be studied by incubating cell suspensions with ^{32}P-orthophosphate, in the absence of any *de novo* synthesis of ribosomal RNA. Any other residual nucleic acid synthesis within the cells can be blocked by the addition of actinomycin and the bulk of the label is incorporated into the ribosomal protein fraction. Acid hydrolysis of the ribosomes yields phosphoserine and phosphothreonine.

Khabat found that about 40 per cent of the phosphorylation was associated with as many as ten loosely bound proteins, associated with polysomes, single ribosomes and ribosomal subunits. These can be removed by thoroughly washing the ribosomes. A further component, which may be GTP but is certainly not a protein, is specifically associated with the polysome fraction, and can be released by dissociating this fraction. He detected at least three *bona fide* phosphorylated ribosomal proteins among the remaining material, by electrophoresis through polyacrylamide gels containing sodium dodecyl sulphate.

One of these proteins, present in the larger subunit, is only found phosphorylated in single ribosomes, although the corresponding non-phosphorylated component is present in the other ribosomal fractions. The molecular weight of this protein is estimated to be about 21,000. A further phosphoprotein, with a molecular weight of about 70,000, is specifically associated with the smaller subunit, but is not found in single ribosomes or polysomes (or in the supernatant fraction) and might well be identifiable with some type of factor, particularly because it can be removed by washing the subunits with buffers of high ionic strength. A further phosphorylated protein, of molecular weight 33,000, is also present in the smaller subunit, and is present in all the ribosomal fractions.

Although ideas about the role(s) of such phosphorylation are very unclear, Khabat makes a salient observation about the kinetics of phosphorylation of the protein from the large ribosomal subunit. It seems that the turnover of the phosphate is comparatively slow, and therefore such phosphorylated single ribosomes do not participate in the usual subunit–polysome cycle of protein synthesis. He therefore suggests that these are inactive ribosomes, and that they may have a storage function. It seems unlikely that reticulocyte ribosomes are unique in this respect; Khabat also reports the occurrence of phosphoproteins in the ribosomes of various chick embryo tissues, promising further information later.

BACTERIA

Group with Obscure Function

from our Nucleic Acids Correspondent

THE little single stranded DNA bacteriophage φX174 continues to occupy a place in the hearts and minds of many molecular biologists, and is particularly associated with the untiring efforts of Sinsheimer and his colleagues, who have used it as a tool to examine many of the problems of DNA replication. Recently, Razin, Sedat and Sinsheimer have illuminated the abstruse but important problem of the methylation of φX174 DNA (*J. Mol. Biol.*, **53**, 251; 1970).

Although it is widely believed that the introduction of methyl groups into DNA *in vivo* must have some major significance, direct support for this article of faith is regrettably sparse. An exception is the likely relationship between methylation and host-controlled modification or restriction. (DNA from *Escherichia coli* strains K12 or B is "modified" in different ways, and if introduced into the other cell type is thereby recognized as "foreign" and degraded–restricted.) Razin *et al.*, however, studied the methylation occurring during growth of the phage in a C strain of *E. coli*. This host does not display modification or restriction, ruling out in this case any link between methylation and these phenomena. They used ^{14}C-methionine to label specifically the methyl groups introduced, with the additional precaution of the strain being a purine auxotroph, so that growth in the presence of adenosine depressed background labelling of the purine rings. Hydrolysis of the phage DNA with trifluoroacetic acid yielded principally radioactive 5-methylcytosine, although a far from negligible amount of thymine was also inexplicably labelled.

They determined the amount of 5-methylcytosine present in the DNA, and conclusively showed by four different methods that there is likely to be one methyl group in each DNA molecule. This suggests that here, as with methylation of RNAs, a specific site within the DNA is subjected to methylation. Additional support for this assumption was afforded by the finding that after depurination of the DNA with diphenylamine and formic acid, fractionation of the pyrimidine isopliths by chromatography on DEAE-cellulose yields a single radioactive dinucleotide. This was identified as either m^{5}C-T or T-m^{5}C, suggesting that the methylation occurs in one or other of the sequences pu-m^{5}C-T-pu or pu-T-m^{5}C-pu. The magical function of this solitary methyl group sadly remains unresolved.

In the same issue of the *Journal of Molecular Biology* (**53**, 205; 1970), an equally esoteric and important

study is described, concerning the way in which colicins act on bacterial cells. These substances are proteins (isolated from so-called colicinogenic strains of *E. coli*) which have powerful antibiotic activity against sensitive strains. They are singular in being adsorbed into specific sites on the membranes of sensitive cells, but not penetrating into the cells. Such sites are only present in sensitive strains. Senior, Kwasniak and Holland have studied the colicin E3 (molecular weight 60,000) which inhibits protein synthesis. In cells exposed to E3, protein biosynthesis is arrested after about five minutes, and is paralleled by the appearance of polyribosomes which dissociate into ribosomal subunits *in vitro* in 1 mM Mg^{2+}. 30S ribosomal subunits isolated from cells treated with E3 are correspondingly deficient in protein synthesis *in vitro*, and Senior *et al.* suggest that the lesion causing both the inhibition of *in vivo* protein synthesis and the curious instability of the polysomes is a modification of the 30S subunits. They show that this can occur whether or not the 30S subunits are actively engaged in protein synthesis. Further study of the mechanism whereby attachment of the colicin to the surface of a cell can cause such a modification of the ribosomal subunits will certainly be of great importance in explaining the means of communication between the cell membrane and the interior.

X-RAY ASTRONOMY

Radiation and Discrete Sources

by our Cosmology Correspondent

THE first of the new informal specialist discussion groups arranged by the Royal Astronomical Society to precede the regular monthly meetings was held on November 13. Topics for discussion were the isotropic diffuse background radiation, pulsar radiation and discrete X-ray sources. The meeting was an undoubted success, confirming the belief that small meetings of experts in one field are more profitable than larger meetings covering diverse topics each of which is understood only by a minority of the audience.

Dr M. Longair (University of Cambridge) gave his own interpretation of the shape of the spectrum of high energy background photons. This follows a power law with index roughly 1·5 for energies below 50 keV and 2·2 for energies above 50 keV but below 1 MeV. The few available data at very low and very high energies deviate from this simple behaviour, with an apparent excess of photons at each end of the scale. But the principal point of discussion concerned the reality of the "knee" at 50 keV. Some theoreticians have argued that this appears only because of observational difficulties, which arise because this change of slope occurs just in the energy range where the sort of detector used to study the radiation changes from proportional counters to scintillation counters.

It was generally agreed that this break is indeed real, and that the problem now confronting observers is to determine the exact range in energies over which the change in slope occurs. At present, the data are sufficiently inconclusive that almost any theory of the origin of this background radiation can be adjusted to allow for the change, but most will fall by the wayside if observations can be improved by a factor of 10 or more.

The isotropy of this radiation was also a point of discussion. Because an energy density of only 10^{-4} eV cm^{-3} is required to produce the radiation, many models can also be constructed to explain this. It is now clear that the radiation really is isotropic to a very large degree, and that if it is produced by many discrete sources of equal intensity then more than 10^4 sources per steradian are required. For this reason, models in which the radiation is produced uniformly throughout intergalactic space (for example, by bremsstrahlung radiation from a uniform hot gas) seem preferable to those which require the radiation to originate in discrete regions and become uniformly spread out during its passage to Earth. It is significant that the isotropy needed for a discrete source model is greater than the isotropy of the distribution of galaxies in space.

Discussion of high energy emission from pulsars was severely limited because only the Crab pulsar is known to emit optical and X-ray pulses. But a very significant experiment carried out by the Bristol group earlier this year has provided meaa sure of the X-ray pulses from this source (NP 0532) above 600 keV. Both the main pulse and precursor seen optically and at radio frequencies were detected, but at these high energies the precursor becomes three times more powerful than the main pulse, which is itself stronger than at lower frequencies. The fraction of the total emission energy which is in the pulse is therefore very large, in contradiction to the earlier belief that only a small part of a pulsar's emission occurs in the pulses. The most profitable way to find other high energy pulsars is therefore to look at young supernova remnants in other galaxies.

Dr M. Rees (University of Cambridge) suggested that the energy content of the pulses during the first months of a pulsar's life might be enough to make them visible as far away as the Virgo Cluster, covering a volume of space in which an average of one supernova a year occurs. Unfortunately, for the first few months of its life a pulsar would be obscured by the cloud of gas expanding away from it as a result of the explosion in which it originated, so that it is not certain that the pulsar will still be strong enough to be seen when the obscuration clears. But high energy astronomers will certainly be looking at hopeful cases in future.

Most of the discussion of discrete X-ray sources centred on the archetypes of the two types of source best known, Sco X-1 and the Crab. Very little of this covered any new ground, although it does seem that there is a consensus in favour of accepting the marginal evidence for greatly broadened lines of highly ionized iron in the spectrum of Sco X-1. The next new developments in this part of the field will probably result from the studies just commencing of the new class of bright low energy discrete sources (with emission only below ~2 keV) like the Cygnus loop. These should provide spectra in which many lines will stand out, and give the theoreticians another chance to revise their estimates of the relative abundances of the elements in our galaxy.

EARTH'S HEAT

Equality over Land and Sea

from our Geomagnetism Correspondent

THE equality of the average heat flows through continents and oceans is one of the major mysteries in geophysics. If, as has commonly been assumed, the principal contribution to the Earth's heat flux is from

the decay of radioactive materials, especially those in the crust, the heat flow at sea should be less than that on land. The fact that there is no such inequality suggests that the chemical composition of the mantle is different beneath continents and oceans; and this immediately creates problems for the new global tectonics, implicit in which is large scale lateral movement of upper mantle material. Several possible explanations have been put forward to account for the unexpected equality; but so far none has carried sufficient conviction to be widely accepted.

The idea that the oceanic and continental equalities might be fortuitous is apparently anathema to many geophysicists. Yet as a result of a new analysis of world wide heat flow data, this is basically what Sclater and Franchetau (*Geophys. J.*, **20**, 509; 1970) suggest. Their analysis is unique in that for the first time they have determined oceanic averages over defined geological age provinces rather than over latitude-longitude "squares" unrelated to geology. Thus the oceans were divided into strips of gradually increasing age as determined from seafloor spreading studies, and mean heat flows calculated as a function of age.

It emerges that in the North Pacific and South Atlantic, at least, average heat flow decreases with the age of the province from 2·82 μcalories cm^{-2} s^{-1} for provinces less than 10 million years old to 1·15 μcalories cm^{-2} s^{-1} through provinces older than middle Cretaceous. This result parallels that previously demonstrated for continents where heat flow decreases with the age of the orogenic province to an apparently constant value of about 1·00 μcalories cm^{-2} s^{-1} for Precambrian shields. In the oceans, the data are compatible with a model in which hot mantle material rises at ridge crests and loses heat by conduction as the new crust moves away laterally. But because in seafloor spreading a significant amount of heat must be lost from the oceanic crust by the creation of oceanic lithosphere—a process not paralleled on land to the same degree—there is no need to assume identical radioactive compositions beneath the surface of oceanic and continental crusts, and thus no need to assume differences in mantle composition. The sources of heat below continents and oceans must be different—a conclusion which is supported by the fact that the time scales for the thermal decay of heat flow beneath continents and oceans differ by an order of magnitude. These radical differences inevitably lead to the conclusion that the basic flow equality is purely coincidental.

So, according to Sclater and Franchetau, the quality is irrelevant. The important questions are rather: (i) why the heat flow decreases with the age of the rock; and (ii) why, in spite of differences in time scale, the heat flow in the older parts of the oceans is about equal to that for Precambrian shields. To solve these problems, Sclater and Franchetau consider two particular geophysical and geochemical models of oceanic and continental crust and upper mantle. They show that each model can explain the near equality of heat flow through Precambrian shields and old ocean basins when plates of oceanic and continental lithosphere move, and that each can account for the heat flow-age variations. The two models are similar in that the thickness of the oceanic lithosphere lies between 75 and 100 km and that the continental plate is about twice as thick, but they differ in the temperature at the base of the oceanic lithosphere. In each case, however, the composition of the mantle is the same under oceans and continents. Sclater and Franchetau have thus shattered a few illusions concerning the Earth's heat flow, and have convincingly demonstrated that unreasonably speculative hypotheses are not required.

HIGH ENERGY PHYSICS

The Intermediary Boson

One of the most formidable obstacles to detecting the intermediary or W boson, the particle believed to mediate the weak nuclear interaction in much the same way that a photon mediates the electromagnetic interaction, is the uncertainty about the exact way that the W boson decays. Experiments have had to be designed to allow for a great variety of possible decays into light particles (called leptons) and strongly interacting hadrons. This is why the results so far of this search for the boson have been quite inconclusive. D. Cline, A. K. Mann and C. Rubbia (*Phys. Rev. Lett.*, **25**, 1309; 1970) have now, however, proposed an experiment which avoids this difficulty and which may even make it possible to carry out a thorough search for the W boson without having to know the relative amounts of hadronic and leptonic decay.

It is perhaps appropriate that Cline *et al.* should have published their proposals so soon after the first successful trials on the intersecting storage rings at CERN (see *Nature*, **228**, 597; 1970), for the search for the intermediary boson is one of the most obvious experiments planned for the new machine. When energies of interaction may be as much as 1,500 GeV, the search for the W boson is more likely to bear fruit than the search for the quark.

Cline *et al.* claim that the hadronic decay modes of the W boson from high energy neutrinos provide a unique and unambiguous experimental signal of the production and decay of the W, even in the absence of information about the number, configuration and momenta of the decay products. The essential point is that the release of large amounts of energy to the hadrons in hypothetical W events is accompanied by a small transfer of momentum to the associated muon. If the boson exists it will therefore manifest itself by a tight clustering of W events in energy which will stand out against a smooth background.

Cline *et al.* point out that the experimental resolution necessary to observe this cluster is easily attainable in either a heavy liquid bubble chamber or some form of ionization calorimeter. The largest uncertainty will probably accrue from the effect of multiple scattering of the muon, they say, but this should not reduce appreciably the prominence of the cluster.

Many suggestions for detecting the W boson depend on detecting the μ-mesons in its decay. The principal decay mode of the W is believed to be into a neutrino and an electron or a μ-meson, but a persistent problem in its detection is a lack of knowledge about the branching ratio. This has produced nebulous conclusions to experiments appearing in the form of an upper limit of the product of the cross-section for W production by a particular leptonic or hadronic decay mode. Cline *et al.* recall that the present lower limit on the mass of the W is sufficient to allow multi-pion decay modes of the W, and that their experiment provides an unambiguous way of recognizing the W through its hadronic decay modes.

Future for Integrated Cognitive Systems

by
DONALD MICHIE
Experimental Programming Unit,
Department of Machine Intelligence and Perception,
University of Edinburgh

Before the mid-1970s integrated cognitive systems are expected to attain performance levels comparable in some respects with a 2 or 3 year old human infant. Many people think that within the next 100 years the level of adult humans will be reached. At present limitations lie in inadequate understanding of mathematical-logical and programming principles rather than in hardware speeds or storage capacities. This article is based on a lecture delivered at the CERN computing and data processing school held at Varenna from August 31 to September 12.

WORK is in progress in several laboratories[1-6] directed towards the construction of an integrated cognitive system (ICS): I avoid the phrase "intelligent robot" because of its science fiction connotation of humanoid appearances and other attributes. The research is concerned with intellectual attributes, involving sensorimotor and reflex capabilities only to the extent that these form a necessary substratum for the acquisition or display by computing systems of purely intellectual skills.

At this early stage the "intellectual" skills which research aspires to emulate may seem to the onlooker so primitive as scarcely to deserve the name. Let him, however, reflect on the struggles of small children with the simplest tasks of deduction, generalization and description, and their dogged attempts to construct and refine world-models adequate for their growing needs, representing a succession through which every developed human intellect has passed. Even these first exploits of the infant mind are beyond the abilities of any computing system yet devised. Computers equipped with optical input and manipulative devices are available in at least two laboratories, but understanding of machine perception and cognition has not advanced so far that they could be programmed to compete with human infants, for example on tasks such as the following, which is taken from Stanford-Binet IQ tests[7]. The task involves obeying simple commands, and is designed for $2\frac{1}{2}$ year old infants. With a brick, a button, a dog, a box and a pair of scissors laid in order on a table, the child is told (*a*) "give me the dog"; (*b*) "put the button in the box", and (*c*) "put the scissors beside the brick". A machine passing tests of this sort would be disqualified if it had merely been pre-programmed *ad hoc* for each individual test. An artificial intelligence worth the name must show some degree of generality.

Problems of abstracting from the world of crude sensations and of planning and physically doing things in space and time are dominant in intellectual activity at this early age—possibly they also form an indispensable springboard for the flights of abstract thinking attained later. Emulation by machine therefore demands, as a matter of technical necessity, the design of non-standard computer peripherals to serve as "eyes", "hands", and the like. The alternative course would be to simulate entire real world problem situations inside the machine —a desperate measure of unimaginable scale and cost. R. L. Gregory (private communication) has truly remarked that the cheapest store of information about the real world is the real world, and this indeed is the rationale of the recent emphasis by artificial intelligence projects on "hand-eye" and "robot" devices.

How long is it likely to be before a machine can be developed approximating to adult human standards of intellectual performance? In a recent poll[8], thirty-five out of forty-two people engaged in this sort of research gave estimates between 10 and 100 years. There is also fair agreement that the chief obstacles are not hardware limitations. The speed of light imposes theoretical bounds on rates of information transfer, so that it was once reasonable to wonder whether these limits, in conjunction with physical limits to micro-miniaturization of switching and conducting elements, might give the biological system an irreducible advantage. But recent estimates[9,10], which are summarized in Tables 1 and 2, indicate that this is not so, and that the balance of advantage in terms of sheer information-handling power may eventually lie with the computer rather than the brain. It seems a reasonable guess that the bottleneck will never again lie in hardware speeds and storage capacities, as opposed to purely logical and programming problems.

Granted that an ICS can be developed, is now the right time to mount the attempt? Is it possible that effort should instead be put into some abstract field of philosophy, linguistics or pure mathematics? Perhaps only by postponing rash attempts to construct actual systems can a sufficiently deep understanding be gained to enable artificial intelligence problems to be tackled in the right way.

Theoretical studies are certainly central. But it is not clear that they would be aided by abstention from experimental work. Indeed the lessons of history point in the opposite direction, as with the relationship between classical thermodynamics and the development of the steam engine. Typically engineering artefacts come first, and provide the theoreticians not only with the needed spur to rationalize what is being done, but also with test gear on which to check their formulations. There are elements of a similar relationship between the robot building now in progress in various laboratories and the recent spate of activity by theoreticians in the same laboratories in two areas in particular: visual scene analysis by machine[1,3,11], and construction and formal description of abstract models of the world for use as the basis of plan-formation[12-14].

Yet the principle of "unripe time", distilled by F. M. Cornford[15] more than half a century ago from the changeless stream of Cambridge academic life, has provided

the epitaph of more than one premature technology. The aeroplane industry cannot now redeem Daedalus nor can the computer industry recover the money spent by the British Admiralty more than 100 years ago in support of Charles Babbage and his calculating machine. Although Babbage was one of Britain's great innovative geniuses, in terms of tangible return on investment, support of his work was wasted money. It is now appreciated that of the factors needed to make the stored-program digital computer a technological reality only one was missing—the means to construct fast switching elements. The greater part of a century had to elapse before the vacuum tube arrived on the scene.

Table 1. A COMPARISON OF INFORMATION-HANDLING POWERS OF BRAIN AND COMPUTER

	Brain	Computer
Speed	1,000 bits traverses 1 neurone in 1 s	1,000 bits transferred in or out of core memory in 1 μs
Store	$10^{12}-10^{15}$ bits	10^{12} bits, retrieval 50 ms

This table is based in part on data from ref. 9. The upper comparison, which appears to give the computer the advantage in speed, is compensated by the brain operating in a highly parallel fashion, as opposed to the sequential processing characteristic of the computer.

Table 2. THE SUPPLY POSITION OF MECHANICAL ENERGY AND MECHANICAL INFORMATION PROCESSING CAPACITY

(*a*) Ratio of energy available from mechanical sources and from human muscle power

Year	1500	1700	1800	1900	1945	1965
ER	10^{-4}	10^{-3}	10^{-1}	1	5	10

Total human muscle power potentially available is assumed to be of the order of $0{\cdot}25{\cdot}10^{9}P$ Wh/annum (P=world population). For 1965 it has been assumed that mechanical energy supply was of the order of 4×10^{16} kcalories or $0{\cdot}75\times10^{16}$ Wh at 15–20 per cent conversion efficiency.

(*b*) Ratio of mechanical and human information processing capacity

Year	1955	1965	1970	1975
CR	5×10^{-4}	10^{-2}	2	50?

This comparison is based on those tasks where the human channel capacity of *c.* 20 bits/s is a major rate determining factor, as may be the case in many routine clerical operations and computations.

As in (*a*), (*b*) attempts to compare facilities available world wide. Both assessments, and in particular (*b*), are obviously very tentative only.

It can reasonably be said that time was unripe for digital computing as an industrial technology. But it is by no means obvious that it was unripe for Babbage's research and development effort, if only it had been conceived in terms of a more severely delimited objective: the construction of a working model. Such a device would not have been aimed at the then unattainable goal of economic viability; but its successful demonstration might, just conceivably, have greatly accelerated matters when the time was finally ripe. Vacuum tube technology was first exploited for high speed digital computing in Britain during the Second World War[16]. But it was left to Eckert and Mauchly[16] several years later to rediscover and implement the conceptions of stored program and conditional jumps, which had already been present in Babbage's analytical engine[17]. Only then could the new technology claim to have drawn level with Babbage's design ideas of 100 years earlier.

How is ripeness of time to be diagnosed for projects to build intelligent machinery? The only absolutely safe method is to wait until someone does it, just as the only error-free pregnancy test is to wait for the birth of a demonstrable infant. We would prefer, I think, to detect what is still in the womb, and accept a risk of being wrong. Table 3 shows four possible criteria of ripeness which might be applied, from the outside as it were, to budding technological enterprises.

The four criteria are listed in decreasing order of superficiality. Criterion 1 is of a kind which can be applied by a policy-maker "off the cuff", without delving into technical considerations. It says "This is not a bee in an isolated bonnet. Laboratories all over the world are in the race. Can we afford not to join?". The fact that it is so widely persuasive stems chiefly from the fact that it is superficial, and hence cheap and easy to apply: also it acts on the "keeping up with the Joneses" reflex. For what it is worth it is favourable to the proposal to construct an integrated cognitive system, which is being studied actively in America, Britain and Japan. But we must remember that the highest recorded score for this particular criterion could probably be claimed for the alchemists.

Table 3. CHECK LIST OF SIGNS AND SYMPTOMS FOR THE EARLY STAGES OF FIVE TECHNOLOGICAL PROJECTS

	A	*B*	*C*	*D*	*E*
(1) Multiplicity of effort (i.e. how many laboratories?)	√	√	X	√	√
(2) Availability or feasibility of all essential instrumentation	X	√	X	√	√
(3) Demonstration of a working model	X	√	X	√	(?)
(4) Theoretical proof of overall feasibility	X	X	X	X	X
Fate: S succeeded F failed	F	S	F	S	?

(*A*) Transmutation of elements in the time of alchemy; (*B*) steam engines in the time of Watt; (*C*) stored-program digital computing in the time of Babbage; (*D*) heavier-than-air flight in 1900; (*E*) intelligent machinery in 1970. The symbol "(?)" is used to mean "possibly imminent" in distinction from "?" which means "undecided".

Jumping to the other end of the range, criterion 4 is in general of little assistance because of the "pregnancy test" argument. Overall theoretical analysis is usually only achieved on the morrow of success. An interesting counter-example is Lovell's project to build a giant radio telescope at Jodrell Bank[18]. Here criterion 4 was satisfied in advance. But of course there was never any problem concerning unripeness of time in the feasibility sense. All that was in question was the balance of expected benefits against expected costs. This issue was finally settled when the first Russian sputnik was successfully tracked by an instrument designed for other purposes, and the world found itself dependent on Jodrell Bank for accurate data on satellite orbits. This decisively ended the era of uncertainties of funding for the project. One may wonder whether some element of international "keeping up with the Joneses" was at work here, to the great good fortune of astronomical science.

An even more interesting case is radio broadcasting. Feasibility was shown theoretically by Maxwell in 1865, and verified experimentally by Hertz about 20 years later. Shortly afterwards Popov and Marconi independently achieved the first "working models". An equally clear example is the modern (junction) transistor, the basic action of which was predicted by W. Shockley in 1949. A further application of criterion 4 arises if theoretical infeasibility is demonstrated, as in the case of the perpetual motion machine. Anti-gravity is another example, in spite of rumours of continued multiplicity of effort behind the security curtain. But it is well to look on such negative proofs with caution. The possibility of broadcasting radio waves across the Atlantic was convincingly excluded by theoretical analysis. This did not deter Marconi from the attempt, even though he was as unaware of the existence of the Heaviside layer as everyone else.

Instrumentation

To summarize the uses of the four criteria, No. 1 is so weak that it is better left alone, while No. 4 is so strong that it is usually not available in real cases of doubt. We are therefore thrown back on criteria 2 and 3. It will be interesting to relate these, if possible, to the present scene in machine intelligence research. First, I shall consider availability of instrumentation. Four categories are involved: (1) computing hardware; (2) programming systems; (3) utility packages (such as deduction routines, parsing routines, learning routines, search routines and so on), and (4) "robot" input–output devices.

These can be interpreted as stages in a development programme. First, get your computer. Then develop a software and programming language base adequate for the needs of machine intelligence research. Only then is it feasible to build a library of useful packages and to construct special peripherals such as "hand-eye" attachments. The next step, at least in aspiration, is the construction of a working model of an intelligent machine. Most workers who partake of this aspiration would, I think, agree that categories 1–4 are beginning to be in reasonable shape to provide the tools for the job.

Working Model

A working model is almost a necessary condition of confidence in the feasibility of any proposed technological innovation. It is by no means a sufficient condition. New and possibly prohibitive difficulties may be brought into being by the scaling-up process. We would do right to be impressed by a power-driven model aeroplane. But suppose that an inventor proposed to develop a man-sized jumping machine able to clear the top of St Paul's Cathedral. A flea-sized model jumping a similar multiple of its own height would scarcely be convincing. So if the objective which I shall discuss were to be attained within the next few years, this would by no means imply that an intelligent machine was round the corner. But it might indicate that significant success at the scaled-up level was perhaps only a decade or two away.

What is meant by a working model of an intelligent machine? The best approach is to map out roughly the principal constituents of such a machine's "mental world", and then say that a working model is constructed on something like the same overall plan, differing only in the relative poverty of the individual subsystems which are linked together. Also it must be "working" in the sense of displaying the various constituents and their collective operation in interaction with real world problems—for example problems of the type illustrated by the Stanford-Binet tests for infants which I cited earlier. An ICS able to operate at this level would bear the same relation to the intelligent machines of the future as a powered toy aeroplane to passenger-carrying airliners. But even such a primitive ICS has two rather interesting features; first, its achievement lies, in the opinion of some workers, only a few years in the future; and second, such an ICS could almost certainly be made the basis of an industrial development programme to produce before the end of the 1970s a range of commercially useful devices.

Applications

At Edinburgh we recently commissioned the consultant firm Scicon Ltd to do a study addressed to the question: "Assuming solution of the technical problems, what industrial applications can be envisaged for the late 1970s"? The possibilities included in their report were, first, anchored devices for luggage-handling at airports, crane-controlled assembly, and automatic control and inspection of machine tool output; and second, free roving devices for exploratory vehicles for the space programme, ocean bed exploration, laying pipe-lines in deserts, and tree-felling in remote forests.

Activities such as these in inhospitable or inherently unstructured environments are difficult and expensive when conducted by conventional means, so that any prospect of delegating them to cognitive machines will have attractions. At Edinburgh we are assisting in a feasibility study of automatic parcel-handling for the Post Office Telecommunications Headquarters, and a Japanese group (see ref. 5) are interested in applications of ICS work to assembly line operations. The robot project at Stanford Research Institute envisages exploratory vehicles of various kinds as a major industrial payoff.

Programs and Plans

Leaving industrial implications, I shall now consider the quintessential activity of an integrated cognitive system, in the sense that locomotion is the quintessence of a motor car. This, it can be argued, is planning, for it is by the relative absence of this activity that we recognize that existing automatic systems of prediction and control, however sophisticated and "clever", are not true examples of intelligent behaviour. Further, when we speak of machines able to form plans and to reason about the adequacy of a plan to a given task we can be quite precise about what we mean, by pointing out that a plan of action can be usefully treated as formally equivalent to a computer program ("plan of computation"). Forming a plan is then seen as having the same logical status as writing a program, and validating a plan as utilizing the same mathematico-logical apparatus which programming theorists have developed in recent years for proving things about programs. This insight, elaborated recently by C. C. Green[12], is of profound importance for the future development of artificial intelligence, and may well be destined to occupy a place as central as, say, the equivalence of the corpuscular and wave models in the theory of optics.

An integrated cognitive system, then, can be conceived as a plan constructor and plan implementer. At any moment it is either in interactive mode or in planning mode. "Planning mode" is interpreted in a broad sense to include all processes of inference involved in the formation of new plans, including purely internal reorganizations or extensions of stored descriptions.

In interactive mode it is executing a plan. No reasoning in the sense used here occurs in this mode, until an interrupt generated by an input device causes reversion to planning mode. Input (for example "eye") and output (for example "hand") devices interact directly with an external world in such a way that the next sense-datum received is dependent on the past input–output sequence. The precise form of this dependency is governed by the laws of nature. It is part of the business of an ICS to form an approximate picture of these by processes of abstraction.

What else is in memory, apart from plans, and to what top-level control are the contents of the memory subject?

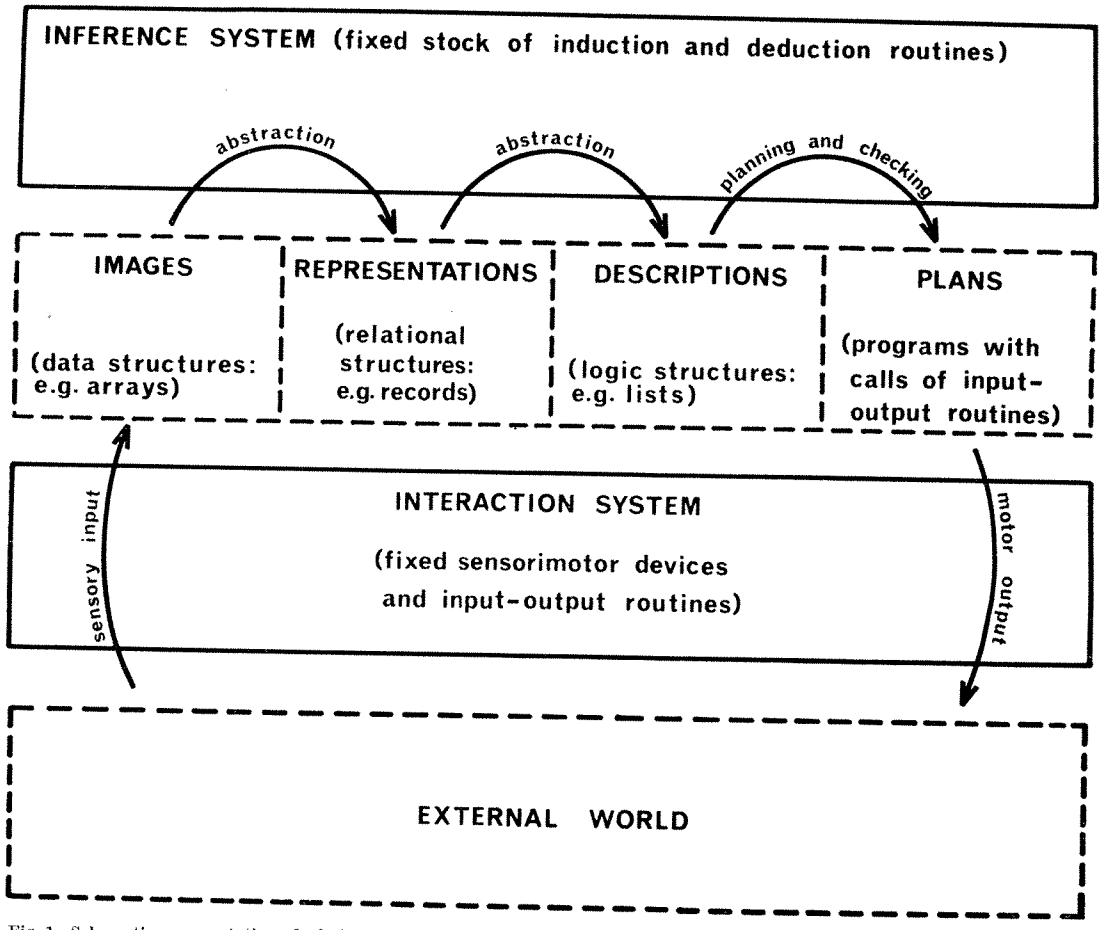


Fig. 1. Schematic representation of relations between an integrated cognitive system and its external and internal worlds. The fixed systems are shown with solid lines, while those which are subject to change in the interaction process are drawn with broken lines.

Four major categories are envisaged (Fig. 1): "plans" (in the form of programs); "images" (in the form of data structures); "representations" (for example in the form of relational structures), and "descriptions" (in the form of logic sentences).

At the top level a common inference system operates on: (*a*) plans, not only to construct them, but to verify in advance that they will work, using in the process: (*b*) images, which are direct point-to-point projections of objects in the external world (for example a map is an image of a particular geographical area); (*c*) representations, which model objects in the external world by abstracted features, and (*d*) descriptions, usually called "theories", which make general statements about objects in the external world and their relations to each other in space and time.

It is worth commenting on the extraordinary faithfulness with which the brain can store images: the extreme case is "eidetic imagery" in which a visual pattern can be stored for periods in considerable detail. It is possible, and has been argued by Richard Gregory[19], that this type of direct modelling is biologically more primitive, and hence has had time to evolve to a higher pitch, than the storage and sequential processing of symbolic information, as in natural language and in formal reasoning.

Automatic Plan-formation

The idea of getting a computer to write its own programs has appeared and disappeared several times in the past two decades. Early attempts, inspired by the example of biological evolution, were based on generating program symbols randomly, conserving the more successful sequences[20,21]. Such an approach is now considered naive, and nature tends to be thought a poor model for cost-conscious designers. Present ideas centre round the systematic construction of a program, either as a side product of mechanically proving from given axioms that the task which the program is to accomplish is theoretically capable of accomplishment, or alternatively as an end-product of a process of heuristic search. Keeping in mind the formal analogy between programs and plans, it may help fix ideas to consider an example from an unpublished study by Popplestone in which elements of both approaches are used.

The theorem-proving approach, developed by C. C. Green, uses the apparatus of formal logic to form plans of action. There are difficulties in the approach. One is the "frame problem": it is necessary to say not only what things are changed by an action, but also what remains unchanged. Not only are the frame axioms tedious to write, but they also tend to lead the theorem-proving process astray. This raises the second principal difficulty, the Achilles heel of present day mechanized proof procedures, that they very easily stray into unprofitable inference paths through lack of any adequate formulations of the notion of relevance.

An alternative approach to plan-construction, suggested by the work of Floyd[22], is to start at the goal and work backwards to the present situation. The goal is repre-

sented by a sentence, which is conceived as having been deduced from the conjunction of a preceding situation (represented by a sentence) and an antecedent action. A backwards search tree can be grown until a state-description is produced which is a logical consequence of what is known about the initial pre-planning situation. This process, which is currently being developed by R. J. Popplestone, is illustrated in Fig. 2 for a housekeeping task in a world furnished with a cupboard, a table and a chair. Initially the cupboard contains exclusively forks and the robot's hand is at the chair. A plan is required to create a situation in which at least one fork is at the table. The example is exhibited here for its didactic value rather than for its originality of approach. Novel features do, however, exist (*a*) in the way in which general statements, rather than detailed specifications, are handled in the search, and (*b*) in Popplestone's method for guiding the search heuristically. For this he uses a notion of approximation to the desired condition of being logically implied by the initial situation. The degree of approximation is estimated from the number of interpretations of the description of the initial situation which are inconsistent with the current one. The smaller this number the more "promising" the given situation as a point of departure for extending the backwards search.

"Hand-eye" Problems

The provision of a suitable formal basis for reasoning about even such simple systems is by no means trivial, and the properties which must be possessed by a satis-

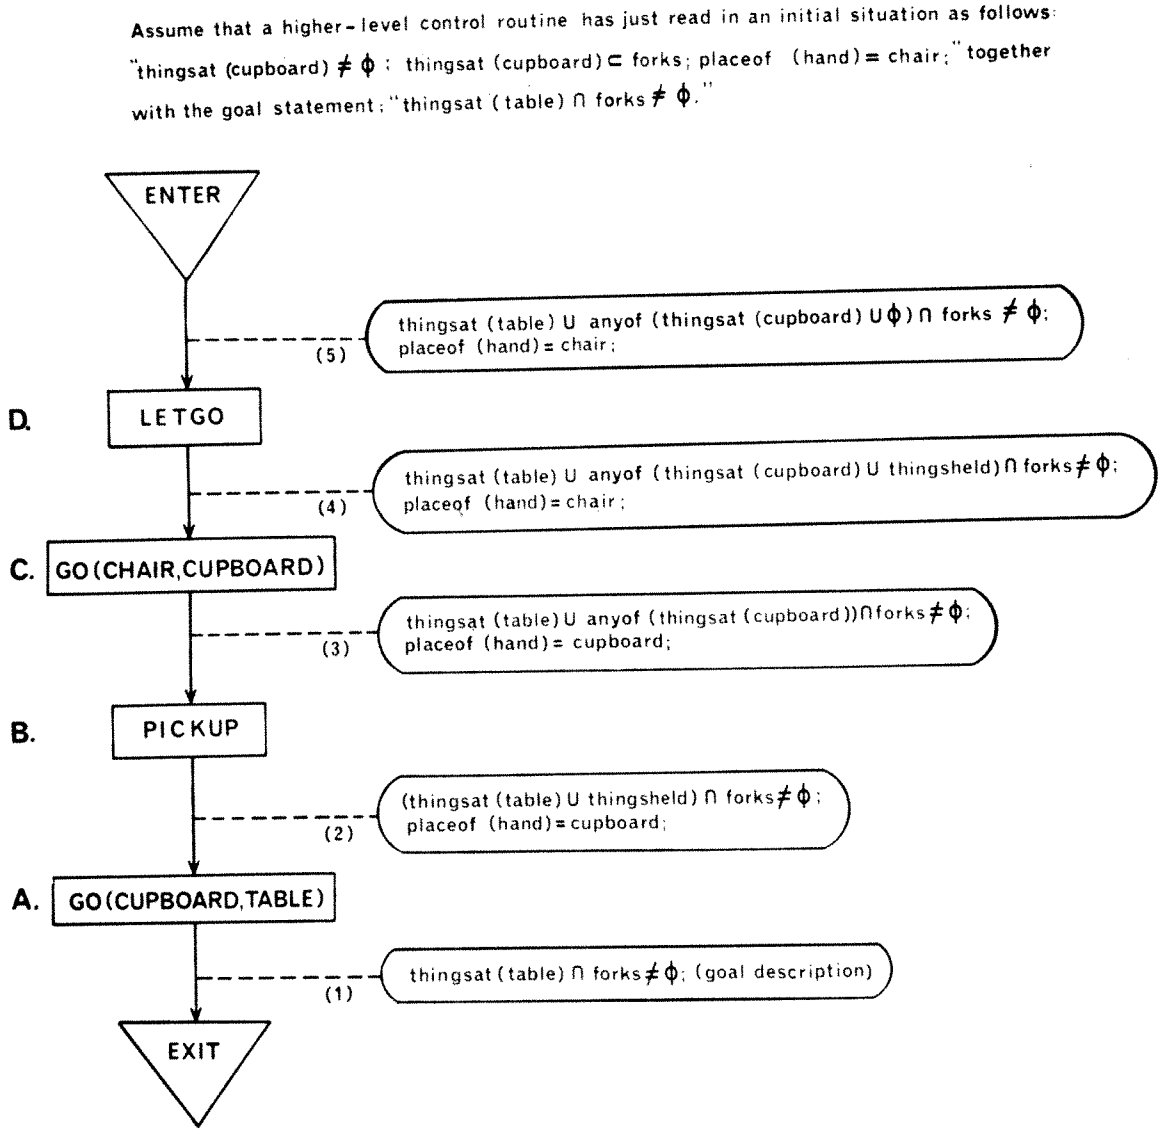

Fig. 2. Successful action-chain constructed by backwards search from the goal situation, using logical inference to associate descriptions with successively earlier situations. The process terminates when a description is produced which is a direct logical consequence of the initial state-description, in this case giving the sequence D, C, B, A as the answer. A plain-language transcription of comments 1–5 might read as follows: (1) there is at least one fork at the table; (2) the things at the table together with the things held in the hand include at least one fork, and the hand is at the cupboard; (3) the things at the table together with a random selection from the things in the cupboard include at least one fork, and the hand is at the cupboard; (4) the things at the table together with a random selection from the things distributed between the cupboard and the hand include at least one fork, and the hand is at the chair; (5) the things at the table together with a random selection from the things in the cupboard include at least one fork, and the hand is at the chair. This last statement can be obtained as a logical deduction from the initial state-description given in the text, so the process is terminated. The method by which description (2) is obtained from description (1) and action *A*, (3) is obtained from (2) and *B*, and so on is due to Floyd[22].

factory calculus of situations and actions have been re-examined by McCarthy and Hayes[13] and by Burstall[14]. In several laboratories, including our own in Edinburgh, experiments are in progress with various "hand-eye" and "robot" attachments to computers in order to provide instrumentation and a software base adequate to put such calculi to the test of practice. Each laboratory doubtless has its own graded repertoire of tasks with which to challenge its local evolving ICS. Our schedule[6], designed to fill the next 2–3 years, is concerned with six types of task: first, as far as vision is concerned we wish to develop a machine that will identify single objects (definitions provided by the programmer) placed within the field of vision, and learn to identify single objects (by generalizing from examples); second, manipulating a hand to move to any accessible prescribed position and pick up an isolated object, and also an object from a group. The third task is that of world modelling to enable the machine to "know" relative locations of objects and "self", and to update the internal model on the basis of sensory input; to integrate several views of an object and tactile information. The fourth is simple planning by simulation (graph traversing[23]), and is concerned with planning a route for "self" from one location to another, avoiding contact with obstacles and planning movements of the hand to pick up an object from a set and move it without disturbing other objects, also executing plans and reforming them if they fail, or are about to fail. The fifth task is that of higher level planning (theorem proving[12]) whereby, given a set of world axioms, means of achieving simple states are designed, for example "Go to a cube", "Put a ball into a cup". The sixth task we have set ourselves comes under the heading of generalization (induction): to learn general statements about simple events from specific occurrences, e.g. " 'Put cup onto ball' implies failure", "'Put ball onto cup' implies success"; to generalize from several similar specific observations, for example "'Put anything onto ball' implies failure"; and eventually to generalize to qualified sets, e.g. "'Put anything flat onto cube' implies success".

Educational Aids for Young Children

There are similarities between some elements of our schedule and the Stanford-Binet tests for infants. This circumstance justified a speculative postscript to the earlier list of industrial uses. It is generally agreed that an important application for advanced computer systems will be in educational technology. It is also already apparent that very young children, for example of primary school age, are in some ways the most rewarding subjects, because the teacher to child ratio is too low fully to satisfy the young child's appetite for continual responsiveness. Anyone who has watched 6 year olds wrestle absorbedly, through the complexities of the teletype, with computer-supplied arithmetic homework cannot help being struck by the motivating power of the interactive terminal. What about even younger age-groups or mentally handicapped older children? Something can be done using the cathode ray display and voice output, permitting communication between child and machine in pictures and words. This possibility is being investigated in our laboratory among others. But just as the human teacher supplements pictures and words with direct demonstrations, by manipulation, for example, of cuisenaire rods for arithmetic, of buttons and beads for sets, of cups and sand and liquid for conservation laws and so on, so it may turn out that when computer terminals can be equipped with adequate "hand-eye" capability these too will be pressed into service as teachers' aids.

The possibility of such a development by the end of the 1970s deserves serious attention. It is particularly attractive for the research worker who likes to have some specific application in mind, because the subject matter of infant teaching has a certain relevance to the intellectual content of artificial intelligence research—namely the explication of real-world phenomena in terms of basic logical and mathematical concepts. To the lay onlooker, however, there may seem to be something de-humanizing, even psychologically dangerous, in the exposure of the very young to interaction with machines. I shall not trespass on the province of the educational psychologist, beyond saying that in our own work with small children at Edinburgh[24] this criticism has indeed been encountered in some quarters; but it has been conspicuously lacking from three specific categories of person—(1) the teachers, (2) the children's parents, and (3) the children themselves.

Differential Binding Properties of Cytochrome c: Possible Relevance for Mitochondrial Ion Transport*

by
E. MARGOLIASH
G. H. BARLOW
V. BYERS
Department of Molecular Biology, Abbott Laboratories, Chicago, Illinois 60064

Similarities between the binding properties of cytochrome c and the permeability properties of mitochondria suggest that cytochrome c may be a transport carrier of the inner mitochondrial membrane. Cytochrome c could be the basis of a mechanism by which mitochondrial activities are regulated by the metabolic state of the cell. Variations in the structure of cytochromes c from different species may result from evolutionary selection for particular ion-binding properties.

THE chief difficulty in understanding the evolutionary variations of the primary structure of cytochrome *c* (refs. 1–3) has been the lack of observable functional differences between the proteins of different species. For example, when properly deionized samples are used, the proteins from the cow, pig, sheep, horse, man, chicken, turkey, pigeon, tuna and the moth, *Samia cynthia*, all yield the same first-order rate constant for their reactions with bovine cytochrome *c* oxidase over a wide range of cytochrome *c* concentrations (unpublished results of L. Smith), even though their amino-acid sequences differ from that of the bovine protein by up to twenty-seven residues out of a total chain length of 104. If such is the case for all biological functions of the protein, then species variations can only result from random processes, such as the evolutionary fixation of selectively neutral variants, and consequently one would expect to observe polymorphism with respect to cytochrome *c* structure in suitably chosen populations of a single species. Such molecular heterogeneity has not been found in the small numbers of individual humans and horses examined[2], but because the protein changes particularly slowly in the course of evolution[1–5], it is likely that a much larger sample would be needed to provide a statistically significant answer to the question of whether such polymorphism occurs[3].

Calculations of Fitch and Markowitz[6], based on statistical phylogenetic trees for cytochrome *c* (ref. 7), have shown that out of the seventy amino-acid positions that have varied in the course of evolution in more than the thirty cytochromes *c* of known structure[2], only about ten positions can sustain variations in any one mammalian species without resulting in the evolutionary disappearance of that line of descent. The number of these "concomitantly variable codons" or "covarions" is a quantitative expression of the stringency of structure-function requirements of the protein. Their paucity in the case of cytochrome *c* indicates that a large portion of both surface and internal residues in this protein is required to be precisely as they are in any one mammalian species. Such a situation is unlikely to reflect a wide latitude of permissible structural variations, all of which would be functionally indistinguishable. It is also difficult to see how more than 90 per cent of the protein could be invariant in any one mammalian species if the only surface requirements are the provision of suitable areas for interaction with cytochrome *c* oxidase, cytochrome *c* reductase, and possibly the mitochondrial inner membrane, the only known functions of the protein. The separate requirement for the third type of interaction has not been demonstrated[8].

Finally, the availability of a 2·7 Å resolution model of ferric horse cytochrome *c* (unpublished results of R. E. Dickerson, T. Takano, P. Eisenberg, O. Battfay, L. Samson and E. M.) has made it possible to locate in the tertiary structure the positions at which evolutionary residue replacements have occurred in the proteins of different taxonomic groups of species. Remarkably, it seems that these are well defined regions for each such group (unpublished results of E. M., W. M. Fitch and R. E. Dickerson). For example, the cytochromes *c* of mammalian species vary within a semicircular band in front, above and behind the haem, leaving both lateral segments of the protein largely invariant (Fig. 1). The insect and plant protein variations are distributed quite differently from those of mammalian cytochromes *c*. Thus, to the extent that neutral mutations may take place, they cannot all be fixed in the same areas in the proteins from different taxonomic groups, indicating again that there must be widespread selective pressures on cytochrome *c* structure and that these are expressed at different sites in the molecule in different groups of species.

Because the classical electron transport functions of cytochrome *c* do not seem to provide the basis for clear cut differences in activity among the proteins from different species which could be related to the degrees of phylogenetic divergence[9–11], we were led to search for other possible physiological functions for the protein. It could still be argued, of course, that not all aspects of the electron transport properties of the cytochromes *c* of different species have been as well examined as the reactions with cytochrome *c* oxidase mentioned above, and that selective effects might be obtained even with degrees of functional difference below the sensitivity of our *in vitro* tests[2]. These are not attractive possibilities, however, in view of the arguments we have presented, which point to particularly stringent structural requirements and presumably correspondingly stringent selective pressures.

Ion-binding Properties

The one property previously shown to exhibit large variations among the cytochromes *c* of different species is the binding of various inorganic anions by the ferric form of the protein[12]. For example, two chloride ions are bound to one molecule. In a particular set of conditions, the ratios of the areas under the electrophoretic boundaries corresponding to one and two bound ions, which presumably reflect the relative binding affinities at each of the two chloride sites, were found to be 0·8, 1·8, 6, 9 and 32 for the screw worm fly, human, hog, pigeon and *S. cynthia* cytochromes *c* respectively[12]. An examination of the binding properties of the ferric and ferrous forms of horse cytochrome *c* for numerous ions by measurement of electrophoretic mobilities gave the results shown in Table 1.

These results indicate a correlation between the ion binding properties of cytochrome *c* and the transport properties[13,14] of mitochondria. There are four classes of substances involved in mitochondrial transport. Some, such as ammonia, penetrate the mitochondrial matrix

* This material was presented by E. M. as part of the Fourth Keilin Memorial Lecture to the Biochemical Society, in Cambridge, on July 8, 1970.

Table 1. ELECTROPHORETIC MOBILITY OF HORSE HEART CYTOCHROME *c* TOWARDS THE CATHODE IN THE PRESENCE OF VARIOUS IONS

	Added ions	Electrophoretic mobility at 1° C, $cm^2/s/V \times 10^5$ Ferricytochrome *c*	Ferrocytochrome *c*
1	None	6·1	4·6
2	Cl^-	3·7; 4·2	4·6
3	Fumarate	2·6; 3·1	3·5
4	Maleate	2·5	2·2
5	Maleate and Cl^-	4·1	—
6	Na^+	6·1	4·7; 5·2
7	K^+	6·1	4·6; 5·1
8	Ca^{2+}	6·1	5·1; 5·4
9	Mg^{2+}	6·1	5·1; 5·4
10	P_i	4·3	2·6
11	P_i	4·4	2·7
12	Succinate	6·2	4·1
13	Succinate and P_i	2·2	—
14	Citrate	1·5	1·3
15	α-Ketoglutarate	1·9	2·9
16	Glutamate	4·9	3·9
17	Aspartate	4·9; 5·5	3·5
18	ADP	3·3; 4·1	—

The electrophoretic mobilities were measured with the model H Spinco electrophoresis-diffusion apparatus in the 2 ml. cells, as described[12]. Unless otherwise stated, all solutions contained 0·407 to 1·017 mM horse heart cytochrome *c* (prepared according to E. M. and Walasek[27] and freed from bound ions by electrodialysis to the isoionic point[12]), 0·10 M Tris-cacodylate buffer (*p*H 7·2) and 0·05 M of the added ions brought to *p*H 7·2 with Tris or cacodylic acid, as required. In experiments 4 and 5 the solutions contained 0·15 M Tris-maleate (*p*H 7·0) and 0·10 M of the same buffer with 0·05 M NaCl, respectively. The solution in experiment 11 contained 0·011 M Tris-phosphate and 0·10 M Tris-cacodylate (*p*H 7·2). The solution in experiment 12 contained 0·05 M Tris-succinate (*p*H 7·2), while that in experiment 13 was the same with the addition of 0·011 M Tris-phosphate. In experiment 18, ADP was 3·8 mM. In all cases the ferricytochrome *c* solutions were dialysed at 1° C against the various buffers. The ferrocytochrome *c* solutions were obtained by reduction with Tris-ascorbate and equilibrated against the various buffers by passage through a 1 × 50 cm column of 'Sephadex G-25' (Pharmacia). Where two electrophoretic boundaries were observed both electrophoretic mobilities are listed.

independently of any transport phenomena, apparently in the unionized form. Others, such as chloride ions, fumarate and maleate, are incapable of penetrating the inner mitochondrial membrane or do so only at relatively high *p*H[13,15,16]. Such impermeant ions were all found to bind strongly to ferricytochrome *c* and much less or not at all to the reduced protein. Of these, maleate showed the strongest apparent binding to ferrocytochrome *c* (Table 1, experiments 1 and 4); even so, the change of mobility towards the cathode of the reduced protein (4·6 to 2·2 $cm^2/s/V \times 10^5$) was considerably less than that of the ferric form (6·1 to 2·5 $cm^2/s/V \times 10^5$). Maleate has been shown to stimulate the entry of isocitrate and ketoglutarate into mitochondria[15] and therefore its status as a strict impermeant is in some doubt. It was also shown that Cl^- competes with maleate for the same binding site or sites (Table 1, experiments 2–5). The third class consists of cations, such as K^+, Na^+, Ca^{2+} and Mg^{2+}, which are capable of being accumulated in the mitochondrial matrix against a concentration gradient by the expenditure of chemical energy. These all bind to ferrocytochrome *c* but not to the ferric protein (Table 1, experiments 6–9), and from the relative areas under the two boundaries it was estimated that K^+ bound only slightly better than Na^+, whereas Ca^{2+} was clearly more strongly bound than Mg^{2+}. Such relative affinities may be reflected in the relative rates of mitochondrial transport of these cations[13]. Equilibrium dialysis experiments have confirmed that Ca^{2+} binds to reduced but not to oxidized cytochrome *c*.

The last class of transported ions consists of a large variety of anionic substances, which flow in and out of the mitochondrial matrix following the concentration gradient, if suitable "counterions" are present. Counterions are presumably fixed to the same sites in the translocating material as the anion studied or moved in response to the *p*H change. No energy expenditure is involved in these movements. Pressman[13] lists ten groups in this last class, each group consisting of the set of permeant anions, the particular counterions which are effective for this group, and in several cases inhibitors which specifically prevent the movement of this group of substances. A translocating material or exchange-diffusion carrier is assumed to exist for each group, for the rate of flow is proportional to the concentration gradient only up to a certain level, above which the mechanism seems to be saturated. Representatives of seven of these ten groups of substances were found to bind to cytochrome *c* in both oxidation states (Table 1, experiments 10–18). Moreover, like the transport of succinate which occurs only in the presence of inorganic phosphate[13], the binding of succinate to cytochrome *c* also takes place only in the presence of phosphate (Table 1, experiments 11–13). The mitochondrial transport of phosphate is blocked by several mercurials[17–19]. Mersalyl, a typical compound of this group, was found not to influence the effect of phosphate on the electrophoretic mobility of cytochrome *c* in either oxidation state. Nevertheless, gel filtration experiments with ^{32}P-phosphate, similar to those commonly used to measure the interaction of micromolecular substances with proteins[20], demonstrated that mersalyl causes a considerable increase in the binding of phosphate to the protein. This might explain the inhibition of mitochondrial transport of the ion because sufficiently firm binding would preclude adequate dissociation from the carrier. Another group of substances depending on an exchange-diffusion carrier consists of ATP and ADP[13,14,21]. In mitochondrial transport the counterions for ATP and ADP can only be ADP and ATP; atractyloside prevents the movement of both nucleotides; and AMP and other nucleotides are transported extremely slowly if at all[14,21]. It was shown, by equilibrium dialysis, that ADP binds to the protein in both oxidation states, in a stoichiometric ratio of roughly two molecules of the nucleotide per molecule of the ferric protein and with an equilibrium constant of the order of 10^3, indicating that there is weak binding; that ATP also binds to cytochrome *c* with approximately one molecule of nucleotide binding per molecule of ferricytochrome *c*; that ADP competes with ATP for the same site; and that atractyloside prevents the binding of ATP. Measurements of electrophoretic mobility confirmed that ADP binds to ferricytochrome *c* (Table 1, experiment 18). The occurrence of two boun-

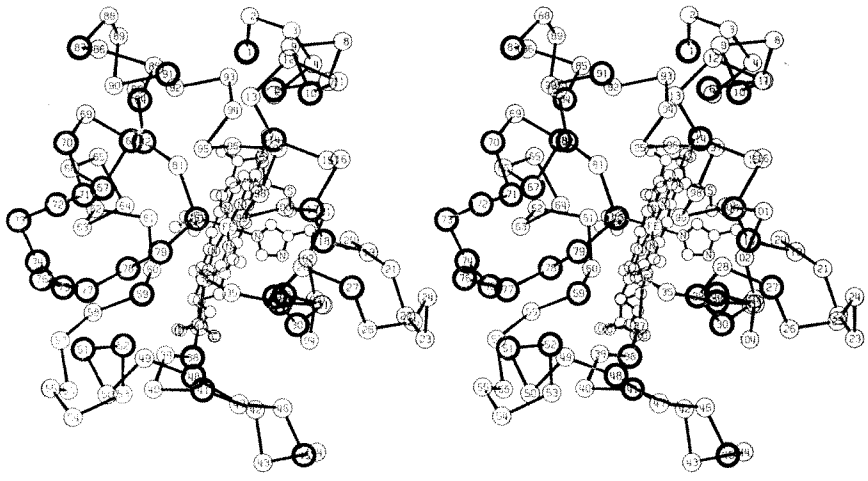

Fig. 1. Stereoscopic α-carbon diagram of the horse heart cytochrome *c* molecule in the ferric form, according to Dickerson *et al.* (unpublished results). Those residues that are invariant among all the over thirty cytochromes *c* of known primary structure are emphasized by heavy circles; those that have varied among the proteins of mammals are 11, 12, 15, 33, 35, 44, 46, 47, 50, 58, 60, 62, 83, 88, 89, 92, 100, 103 (a total of eighteen). Those that represent variations in the cytochromes *c* of primates are 11, 12, 15, 46, 47, 50, 58, 62, 83, 89 (a total of ten), according to Fitch *et al.* (unpublished results). The amino-acid sequences of the cytochromes *c* are given in refs. 1–3.

daries, both of which migrated slower than the free protein, also confirmed the presence of at least two ADP binding sites on cytochrome *c*.

Model for Cytochrome *c* as an Ion Carrier

On the basis of this correlation between the transport properties of mitochondria and the binding properties of ferro and ferricytochrome *c* for typical non-penetrating anions, for the cations which can be accumulated in mitochondria, and for representatives of some of the groups of anions which can undergo exchange-diffusion processes through the inner mitochondrial membrane[13], it is suggested that cytochrome *c* is a carrier for some of the substances which require specific translocation mechanisms to move in or out of the mitochondrial matrix. A diagrammatic representation of the proposed model is given in Fig. 2. This shows that cytochrome *c* reduction takes place near the outer surface of the inner membrane, and that, on reduction, cations such as Ca^{2+} are bound to the protein, whereas any non-permeant anions such as Cl^- that are bound to the ferric form of the protein are discharged. Similarly, near the inner surface of the inner mitochondrial membrane oxidation of cytochrome *c* occurs by reaction with cytochrome *c* oxidase; permeant cations are discharged whereas impermeant anions such as Cl^- are bound. Substances which move by exchange diffusion, such as ADP and ATP, are shown to be bound by both oxidation states of the protein. Clearly, such substances would not penetrate into the mitochondrial matrix either if the binding affinity for the carrier is too low—as may be the case for succinate in the absence of phosphate (Table 1)—or if the binding is too strong and no substance capable of competing for the same carrier site or "counterion" is present. In that case the movement of the substance down its concentration gradient will be slow, for it depends on the weak dissociation from the carrier at the low concentration side of the membrane. Such may be the case for citrate and ketoglutarate (Table 1) in the absence of counterions. Similarly, counterions may have several possible roles. They could merely bind to the carrier and prepare a site suitable for the binding of the transported material, such as may occur with phosphate and succinate (Table 1). Alternatively they could react with the same carrier site as the ion transported and, if the binding affinity to the carrier is within a useful range of that of the transported ion, net exchange would be greatly speeded up in the presence of appropriate counterions in the compartment into which the anion must flow. Counterions could also bind to different carrier sites and merely move out of the mitochondrial matrix in response to the electrochemical gradient generated by the inflow of the transported anion[13]. Finally, inhibitors of ion transport may act by either inhibiting binding to the carrier (atractyloside and ATP or ADP) or causing too firm a binding (mercurials and inorganic phosphate). Clearly, other modes of action are also possible.

The mechanical details represented in Fig. 2 should not be taken literally. In the first place, the arrows connecting the reduced and oxidized forms of cytochrome *c* need not necessarily represent physical translation of the molecule from one side of the membrane to the other. Rather, the "cytochrome *c* pool" could possibly contain a number of molecules of cytochrome *c* in local oxido-reduction and ion-binding equilibria, the movement of individual protein molecules being limited largely to the rotations necessary to bring the appropriate electron and ion donating and accepting sites in contact. Such an arrangement would also be useful in enhancing the specificity of transport. Indeed, if, for example, the carrier protein has binding affinities for two ligands L_1 and L_2 which are in a ratio of 1·1, and if on average each ligand molecule sequentially binds four times to carrier molecules during its transport through the membrane the overall effective, ratio of the binding affinities of L_1 to L_2 will be $(1{\cdot}1)^4$.

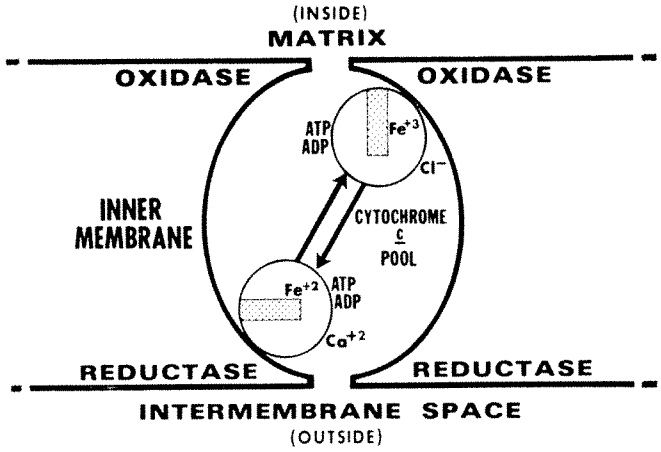

Fig. 2. Diagram of the proposed model for the ion-carrier function of cytochrome *c* in the mitochondrial inner membrane. The smaller circles in the "cytochrome *c* pool" represent cytochrome *c* in the reduced (lower circle) and oxidized forms (upper circle). The cross-hatched areas represent the haem prosthetic group of the protein and are placed to indicate that the orientation of cytochrome *c* with respect to the membrane surfaces is not the same near the outer (reductase area) and inner (oxidase area) surfaces. Ca^{2+}, Cl^-, ATP and ADP represent the corresponding ions bound to the cytochrome *c* surface, Ca^{2+} being an example of the class of cations which can accumulate in the mitochondrial matrix through the expenditure of chemical energy, Cl^- an example of an impermeant anion, and ATP and ADP examples of anions which are translocated by exchange-diffusion processes.

Such a mechanism could also account for the very large effect of temperature on the rates of transport of some substances across the mitochondrial membrane so well documented in the cases of ADP and ATP[21]. Second, though the oxidase and reductase sites are shown in Fig. 2 near the inner and the outer surfaces of the membrane, respectively, this is not essential. All that is necessary is that at the reductase site the external fluid is available for contact with the cytochrome *c* while at the oxidase site the internal fluid is similarly available, and that at each site the carrier molecules are properly oriented to carry out the exchanges postulated here.

It should be emphasized that the model depicted in Fig. 2 does not present any explicit picture of the coupling of the energy-yielding mechanism with cation transport. Moreover, the evidence presented for this scheme is entirely indirect, consisting only of a correlation between the binding properties of cytochrome *c* for various ions, and the transport properties of the mitochondrial inner membrane in which cytochrome *c* is located. Even that evidence is incomplete, for only some seventeen substances and one cytochrome *c* have been examined out of the several dozen ions and the several varieties of mitochondria studied for their transport phenomena. Direct evidence could in principle be obtained by finding which carrier systems are depressed in mitochondrial preparations from which the original cytochrome *c* has been removed, and by showing that when the cytochrome *c* is replaced by the protein from another species the ion transport properties are now those of he re-incorporated cytochrome *c*, not those of the original mitochondria. Differences in the transport properties of mitochondria possibly suited to such experiments have been reported for Ca^{2+} accumulation in mammalian and yeast mitochondria[13,22,23], and for succinate transport in mammalian and fly mitochondria[16,24]. These and similar experiments are predicated on the assumption that one can obtain mitochondria sufficiently depleted of cytochrome *c* to make the rate or inhibition of transport of carried molecules critically dependent on the amount of the presumed carrier, within the ranges measurable by available techniques. Such tests are being attempted and X-ray crystallography is being used to locate the more tightly bound ions on the protein surface.

Metabolic and Evolutionary Consequences

Finally, if the above hypothesis is correct, cytochrome *c* may act as a mitochondrial probe of the metabolic state of the cell outside the organelle and may possibly represent the controlling device which integrates the activities of the mitochondrion with the energy metabolism of the rest of the cell. The controlling influences of the ATP/ADP ratio[25] and of citrate[26] have been amply documented and need no elaboration here. It is yet to be determined whether other ionic substances possibly transported via cytochrome *c* also function in metabolic control systems. The present hypothesis should also lead to predictions concerning the transport characteristics of the mitochondria of different species on the basis of the binding properties of their cytochrome *c* and, in general, cytochrome *c* binding studies should make it possible to determine the action of many substances on mitochondrial transport. From the evolutionary point of view, it is particularly interesting that as the cytochromes *c* of different species have quantitatively very different binding properties for some impermeant anions[12], it is likely that such differences will extend to other substances bound by the protein. Thus as the transport of such ions across the mitochondrial membrane is of metabolic importance, the differences in the structures of the cytochromes *c* would have definite functional repercussions. One could then hope eventually to understand in detail how the structures of the different cytochromes *c* are adapted to the metabolic activities of the particular species in which they reside.

We thank Dr A. Schejter for making available and discussing his studies of the effect of specific ion binding on the oxidation-reduction reaction of cytochrome *c*, Drs W. M. Fitch, I. M. Klotz, H. Lardy, L. Lorand and E. C. Slater for discussion of various sections of this work and numerous suggestions, and Drs R. E. Dickerson, W. M. Fitch and L. Smith for permitting citation of their unpublished work.

Stereochemistry of Cooperative Effects in Haemoglobin

by

M. F. PERUTZ

MRC Laboratory of Molecular Biology, Hills Road, Cambridge CB2 2QH

The oxygenation of haemoglobin is accompanied by structural changes in the subunits triggered by shifts of the iron atoms relative to the porphyrin and, in the β-subunits, also by the steric effect of oxygen itself. The oxygen-free form is constrained by salt-bridges which are broken by the energy of haem–haem interaction with the release of H^+. 2,3-Diphosphoglycerate may add to the constraints by being stereochemically complementary to a site between the β-chains; this complementarity is lost on oxygenation.

Haem–Haem Interaction and the Problem of Allostery

I WISH to propose a stereochemical mechanism of haem–haem interaction which is based partly on a comparison of the atomic models of native deoxy and methaemoglobin of horse[1–3], and partly on an X-ray study of a haemoglobin derivative in which the transition from the quaternary structure of oxy- to that of deoxyhaemoglobin was inhibited (my unpublished results). For a description of the anatomy of the haemoglobin molecule and of the change in quaternary structure that accompanies its reaction with ligands, I refer the reader to previous publications[1,4,5]. The basic features of the molecule are shown in Figs. 1 and 2. I start by summarizing the nature of haem–haem interaction and then go on to describe relevant structural and other observations. I then explain the proposed mechanism, discuss its implications for the size of the functional unit of haemoglobin, and finally apply it to the theory of allostery. In the following article I shall deal with the stereochemical mechanism of the Bohr effect and of the regulatory function of 2,3-diphosphoglycerate.

Nature of Haem–Haem Interaction

This is best explained by analogy with the biblical saying "To him who hath shall be given"[6]. Suppose we have two haemoglobin molecules *A* and *B*, *A* holding three molecules of oxygen already and *B* holding none; to which of them will an approaching free oxygen molecule stick? The chances are 70 to 1 in favour of *A*. If *Y* is the fractional saturation of haemoglobin with oxygen, *p* its partial pressure and *K* and *n* are constants, then the oxygen equilibrium curve can be roughly represented by Hill's equation

$$Y = \frac{Kp^n}{1 + Kp^n}$$

which corresponds to the equilibrium $Hb_n + nO_2 \rightleftharpoons Hb_n(O_2)_n$, Hb representing the haemoglobin concentration in equiva-

lents of iron. Hill's equation fits the experimental data best for a Hill's constant $n \sim 2{\cdot}7$; this value is independent of pH and temperature. More accurately, the oxygen equilibrium curve can be represented by Adair's equation which contains four separate equilibrium constants for the reactions of successive haems with oxygen[7,8]. Monod, Wyman and Changeux[9] have shown that on the basis of simplifying assumptions two arbitrary constants give reasonable agreement with observation, and have used haemoglobin as a model of an allosteric enzyme.

Wyman pointed out the main features which any model of haem–haem interaction would have to satisfy[10]. These are illustrated by his logarithmic plot of the oxygen equilibrium curve which has a slope of unity at very low and very high oxygen concentrations and a slope of about three in the middle range, corresponding to Hill's constant. The total free energy interaction ΔF can be calculated from the perpendicular distance between the two asymptotes and normally lies between 2·5 and 3 kcalories per iron atom. Wyman writes: "In principle, the interaction energy might equally well be interpreted as a stabilizing energy between the unliganded or the liganded haems. In the former case we might say, figuratively, that the first oxygen enters the molecule with more difficulty than the second owing to the necessity of breaking up a pre-existing partnership between the haems; in the latter case the second oxygen enters more easily owing to the decoying effect of the first"[10]. We now know that the former alternative is correct, because the oxygen affinity of isolated α and β subunits corresponds to that of the fully combined oxyhaemoglobin, showing that the low oxygen affinity of deoxyhaemoglobin must be the result of constraints imposed on this form. This is confirmed by its structure.

The physiological purpose of haem–haem interaction lies not so much in ensuring an increased oxygen affinity as successive molecules of oxygen combine, as in making the affinity fall as successive oxygen molecules dissociate. This is because the partial pressure of oxygen in the tissues is not much lower than in the lungs. If haemoglobin had a hyperbolic oxygen equilibrium curve, not more than a small fraction of the oxygen carried by it would be drawn off, with the result that man would asphyxiate even if he breathed pure oxygen. The Bohr effect and 2,3-diphosphoglycerate both increase the efficiency of respiratory transport further by lowering the oxygen affinity of haemoglobin in the tissues.

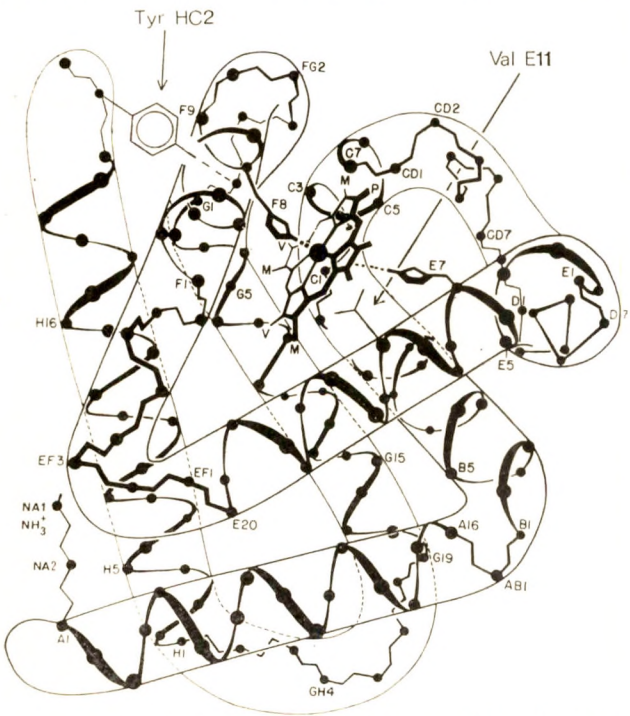

Fig. 1. Diagrammatic sketch showing the course of the polypeptide chain in the β subunit. In going from the amino to the carboxyl end, helical regions are denoted A to H; non-helical residues at the amino end NA, and at the carboxyl end HC. Non-helical regions between helices are denoted as AB, BC and so on. The haem lies in a pocket between helices E and F. The conformation of the α subunit is closely similar, except for the addition and deletion of certain residues.

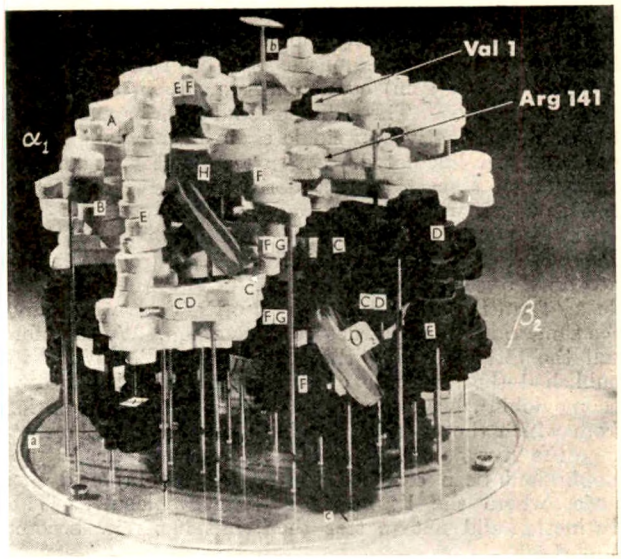

Fig. 2. View of the oxy or methaemoglobin molecule showing the α-chains in white, the β-chains in black and the haems in grey. The sign in the centre indicates the two-fold symmetry axis which runs down the water-filled central cavity. The terminal regions of the α-chain are near at the top, those of the β-chains near the bottom of the molecule. In the deoxy form, the cross-links between the α-chains lie in the central cavity; those between lysine $40\alpha_1$ and histidine $146\beta_2$ lie near the letter H of the label HS in the lower centre of the molecule. The label HS indicates the position of the reactive cysteins 93β. On deoxygenation, the FG region of the α_1-chain turns away from, and that of the β_2-chain turns towards, the observer.

Movements of Iron Atoms relative to the Porphyrin

X-ray studies of iron porphyrin compounds have shown that the length of the bond from the iron atom to the nitrogen atoms of the porphyrin ring varies between 2·061 Å in high spin ferric and 1·99 Å in low spin ferric compounds[11,12]. In metal-free porphyrin the distance from the centre of the ring to the nitrogen atoms is 2·01 Å, smaller than the Fe–N distance in high spin, and larger than that distance in low spin compounds. In six-coordinated low spin ferric porphyrin complexes, therefore, the iron atom tends to lie within 0·05 Å of the plane of the four nitrogen atoms[12]. In five-coordinated high spin ferric compounds, on the other hand, the iron atom is forced to lie out of that plane by distances of between 0·38 and 0·47 Å (ref. 11) (Table 1).

No crystal structures of ferrous porphyrins have been published, but the radius of ferrous iron in low spin compounds is believed to be the same, within 0·02 Å, as that in low spin ferric compounds, so that the iron atom in low spin ferrous compounds should also lie within 0·05 Å of the plane of the nitrogen atoms. The radius of the high spin ferrous iron, on the other hand, exceeds that of the high spin ferric by 0·12 Å (ref. 13). If we add this to the Fe–N distance of 2·061 Å in the five-coordinated high spin ferric form, we obtain an Fe–N distance of 2·18 Å. This would place the iron atom 0·83 Å out of the plane of the four nitrogen atoms.

Of ferrous haemoglobin or myoglobin derivatives, the deoxy form is high spin and five-coordinated, so that we should expect the iron atoms to lie about 0·8 Å out of the plane of the four nitrogen atoms, while oxy and carbonmonoxy forms are both low spin and six-coordinated so that the iron atoms should lie in that plane. All ferric derivatives are six-coordinated, the acid and fluoride met derivatives being high spin and the remainder

low spin. In agreement with expectation, the iron atoms in (high spin) acid metmyoglobin and meterythrocruorin lie 0·3 Å from the plane of the porphyrin ring[14,15], while those in a (low spin) cyanomethaemoglobin of lamprey lie in the plane[16]. Three-dimensional Fourier analyses of the deoxy derivatives of single chain haemoglobins have not yet been calculated. Difference Fourier analyses of deoxy with respect to met derivatives give conflicting results which will be discussed elsewhere.

The quaternary structure of mammalian haemoglobin depends only on the coordination of the iron atom but not on its valency or spin state. The structure of the deoxy form is unique, whereas all other derivatives have the same quaternary structure in common. We therefore call the latter simply "the liganded form". When we published the structure of that form we called it oxyhaemoglobin[1], because this was the state of the solution from which the crystals had been prepared, but by the time the X-ray data were collected, most of the haemoglobin had been oxidized to the (high spin) acid met state, where the ligand is a water molecule. This distinction did not matter then, but has now become important.

When Dr H. Muirhead and I measured the atomic coordinates of methaemoglobin using a plumb line and an electron density map drawn on the scale of 1 Å = 5 mm we did not believe our resolution of 2·8 Å to be sufficient to determine the displacement of the iron atoms out of the plane of the porphyrin ring[1]. But by redrawing the maps on a scale of 1 Å = 2 cm and viewing them in Dr F. M. Richards's reflecting box[17] it was clear that we had underestimated the information contained in them. Dr W. Bolton and I had no difficulty in fitting the porphyrin exactly to the contours. On measuring the perpendicular distance from the plane of the porphyrin ring to the observed iron peak, we found it to be 0·3 Å in both the α and β subunits, in exact agreement with the displacement of the iron atom observed in metmyoglobin[14] and meterythrocruorin[15]. Performing the same experiment with the electron density maps of deoxyhaemoglobin, on the other hand, revealed a displacement of 0·75 Å in both the α and the β subunits, in close agreement with the value of 0·83 Å calculated above. Both displacements are on the side of the proximal histidine (F8). In these measurements we kept the porphyrin ring flat. When we tried to make it slightly domed, as it is in haemin chloride[18], the displacement of the iron atoms from the plane of the four nitrogens came out smaller but their displacements from the mean plane of the light atoms remained the same.

According to R. J. P. Williams, theory predicts that the length of the bond linking the iron atom to Nε of the proximal histidine will also increase by 0·1–0·2 Å in going from a low spin to a high spin ferrous derivative. According to J. L. Hoard it should remain unchanged[11]. Our X-ray data are indecisive. Depending on its exact value, the distance of the proximal histidine from the plane of the porphyrin ring should increase by 0·75–0·95 Å. Such a shift, occurring in the transition from oxy to deoxyhaemoglobin, would be sufficient to force drastic changes in the contacts between the porphyrin ring and the tightly packed amino-acid side chains of the surrounding globin. Hoard first predicted that the reaction with oxygen should be accompanied by a substantial movement of the iron atom relative to the porphyrin ring, and that this could lead to cooperative movements in the protein framework of the haemoglobin molecule[30].

Room in the Ligand Pocket

Haem is attached to globin by a covalent bond extending from the iron atom to Nε of the proximal histidine F8. On the distal side, not directly linked to the iron atom, lie histidine E7 and valine E11 (Fig. 1). The ligand comes to lie between the iron atom and these two residues. Further removed from the iron atom 60 atoms of the globin are in van der Waals contact with the porphyrin ring (Fig. 2 of ref. 1).

We first select the smallest ligand that produces full haem–haem interaction. This is a hydroxyl ion, with a van der Waals radius of 1·5 Å, which becomes attached to the iron atom in the oxidation of deoxy to methaemoglobin at alkaline *p*H. A hydroxyl ion, placed at the expected distance of 2·1 Å from the iron atom in either the α or the β subunits of the liganded form or in the α subunit of the deoxy form, can be accommodated without making short contacts with neighbouring amino-acid side chains. In the β subunits of the deoxy form, on the other hand, the γ methyl of valine E11(67) would come to lie within 2·5 Å of the hydroxyl ion, which is 1 Å less than the sum of the van der Waals radii, so that there is not enough room for even the smallest ligand, let alone an oxygen molecule. Direct comparison of the electron density maps of the β-chains confirmed that the distance between the prophyrin ring and valine E11 shrinks by about 1 Å in going from the met, or oxy, to the deoxy form. Similarly, the difference electron maps of deoxy minus met-BME-haemoglobin, to be described, show a striking movement of valine E11 towards the haem group. These observations demonstrate that in the deoxy form of the β-chains the valines E11 must move relative to the porphyrin ring before the iron atoms can react, and that in going to the oxy form the distance between the porphyrin and helix E widens to make room for ligands. The width of the pocket in the α-chain, on the other hand, shows no measurable change, and has room for ligands in both forms.

Role of the C-terminal Residues

In oxy or methaemoglobin the C-terminal residues of all four chains have complete freedom of rotation, and the penultimate tyrosines have partial freedom in the sense that they spend only a small fraction of their time in their bound position, between helices F and H. The experimental evidence for this statement will be reviewed in the following article. In deoxyhaemoglobin, on the other hand, each of the C-terminal residues is doubly anchored by salt-bridges. The α-carboxyl of arginine HC3(141)α_1 is linked to the α-amino group of valine NA1(1)α_2, and its guanidinium group to aspartate H9(126)α_2. The α-carboxyl of histidine HC3(146)β_1 is linked to the ε-amino group of lysine C5(40)α_2 and its imidazole to aspartate FG1(94)β_1 (see Figs. 1 and 2 of the following article). All four penultimate tyrosines are firmly anchored in pockets between helices F and H, partly by van der Waals contacts with the helices and partly by hydrogen bonds between their OH groups and the carbonyls of valines FG5 (refs. 2 and 3). The conformation is such that the tyrosines cannot be displaced from

Table 1. DIMENSIONS OF IRON PORPHYRIN COMPLEXES (Å)

Compound	Centre of ring to N_{porph}	Fe–N_{porph}	Fe–axial ligands	Out of plane displacement	Fe Valency	Spin
Porphyrin[11]	2·005–2·006					
Chlorohaemin[15]	2·008	2·062	Cl at 2·218	0·475	3+	High
Acid metmyoglobin, meterythrocruorin and methaemoglobin			Nε at 1·9	0·3	3+	High
			H_2O at 2·1			
Deoxyhaemoglobin		**~2·18 (calc)**	**Nε at 1·9–2·1?**	**0·75**	**2+**	**High**
Bis(imidazole)-αβγδ-tetraphenyl-porphinate Fe(III)Cl (ref. 12)	1·989	1·989	Nε at 1·957 and 1·991	<0·01	3+	Low
Cyanomethaemoglobin of lamprey[16]				<0·1	3+	Low
CO erythrocruorin[15]				~0·05	2+	Low

their pockets without also displacing the C-terminal residues and rupturing their salt-bridges. I shall show this property to be vital for the entire mechanism of interaction between the subunits (Fig. 3).

Enzymatic removal of the C-terminal residues affects haem–haem interaction. Amputation of histidine HC3(146)β has the smallest effect, reducing Hill's constant from 2·7 to 2·5 (ref. 19). But Dr J. Greer pointed out to me that this does not mean that the salt-bridge of its carboxyl group with lysine C5(40)α is unimportant, because the α-carboxyl group of the histidine which normally forms the salt-bridge can be replaced in the truncated haemoglobin by the α-carboxyl of tyrosine HC2(145). Displacement of the C-terminal histidine by N-substituted maleimides, attached to cysteine F9(93)β, reduces Hill's constant to about 2·0 (ref. 31). In these derivatives the salt-bridge with lysine C5(40)α is not made, but the remaining structure of the α and β-chains is left undisturbed in both the oxy and deoxy forms. Removal of arginine HC3(141)α diminished Hill's constant to 1·7; removal of both the histidine and the arginine reduces Hill's constant to near unity as well as inhibiting most or all of the Bohr effect (ref. 19 and unpublished results of J. V. Kilmartin, J. Wootton and J. A. Hewitt).

Why should removal of these residues inhibit interaction? Because they are free in oxyhaemoglobin, they clearly serve no function there. Even in deoxyhaemoglobin their positions are such that they could exert no direct influence on the conformation of the haem groups or their immediate environment. We are driven to conclude that their importance for haem–haem interaction lies in the constraining crosslinks they form between the subunit in deoxyhaemoglobin.

This is confirmed by X-ray studies of the derivatives just described which were crystallized by Dr J. V. Kilmartin. Human Des-His-146β and Des-Arg(141)α-deoxyhaemoglobin each crystallize isomorphously with normal human deoxyhaemoglobin. Des-His-(146)β + Des-Arg-(141)α deoxyhaemoglobin, on the other hand, crystallizes in a form closely related to normal oxyhaemoglobin. This shows that in the absence of the constraining salt-bridges the quaternary deoxy structure is unstable, even if all four chains are in the deoxy state.

Conformational Changes within the α and β Subunits

Before the quaternary structure of the haemoglobin molecule can change from the deoxy to the oxy form, the reaction of the iron atoms with oxygen or other ligands may cause the tertiary structure of the individual subunits to alter, so leading to the rearrangement of the subunits. These initial changes cannot easily be observed on electron density maps of the fully liganded or the fully deoxygenated forms. I therefore tried to detect them in a haemoglobin derivative whose quaternary structure is locked in the oxy form.

The lock is *bis*-maleimido-methyl ether (BME), a bifunctional reagent which inhibits all cooperative effects in haemoglobin by linking cysteine F9(93) to histidine FG4(97) in the same β-chain[20–22]. The reagent, which lies in the $\alpha_1\beta_2$ contact, also blocks the entry of the penultimate tyrosines HC2(145) of the β-chains into their pockets between helices F and H, and causes small changes in the remainder of the β-chains and the C-helix of the α-chains[22]. Difference electron density maps of met minus deoxy BME-haemoglobin should therefore show the initial changes undergone by the subunits on reaction with ligands.

Crystals of horse met and deoxy BME-haemoglobin are isomorphous with crystals of the native methaemoglobin, so that the phase angles of the X-ray reflexions should be approximately the same. The crystals had been grown in the acid met form. I reduced them, collected X-ray data to 3·5 Å resolution and, with the help of Dr J. Greer, calculated difference Fourier syntheses.

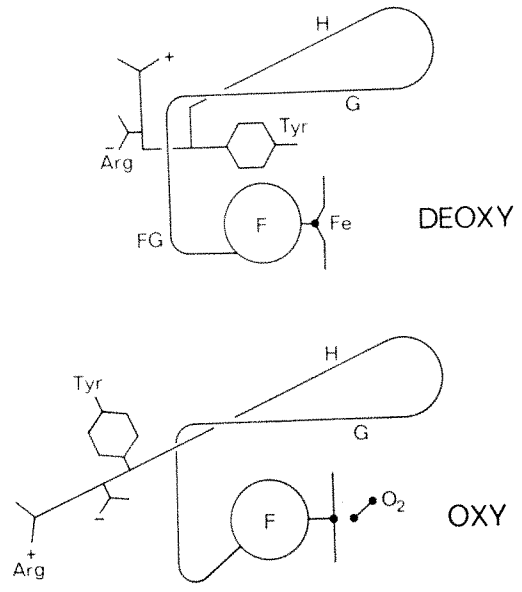

Fig. 3. Diagrammatic sketch showing the change in tertiary structure of the haemoglobin subunits on reaction with ligands. Movement of the iron atom into the plane of the porphyrin ring causes a movement of helix F towards helix H, which expels tyrosine HC2 from its pocket between the two helices.

When acid methaemoglobin is reduced, the haem-linked water molecule is removed and shows up as a positive peak in a difference map of met minus deoxy. The strength of that peak is a measure of the fraction of the iron atoms in the crystal that have been reduced. I first used ferrous citrate and found it had reduced most of the iron atoms in the β subunits, but very few of those in the α subunits. I next used $Na_2S_2O_4$ which reduced all the iron atoms in the β subunits and most of those in the α subunits. Ligands must be removed from the β-chains more easily than from the α-chains.

Difference electron density maps of met with respect to deoxymyoglobin and erythrocruorin reveal no significant changes in the conformation of the globin chain or movements of the haem relative to the globin. By contrast, the difference maps of met minus deoxy BME-haemoglobin show striking changes.

In the α-chains, the positive peak representing the entry of the haem-linked water molecule is matched by a negative one of the same magnitude representing the expulsion of tyrosine HC2(140) from its pocket between helices F and H. There is a further negative peak in the position of the amide group linking tyrosine HC2(140) to arginine HC3(141), corresponding to the fixed position which that amide normally takes up in native deoxyhaemoglobin. There is no positive peak corresponding to this amide, however, showing that it is rotating as freely in BME met as in native methaemoglobin. There are no peaks corresponding to either the side chain or the carboxyl group of arginine HC3(141), showing that these rotate freely in both forms of BME-haemoglobin.

There is a pair of positive and negative peaks indicating that helix F moved inwards, towards the centre of the molecule, narrowing the pocket between it and helix H. This looks like the movement responsible for the expulsion of tyrosine HC2 (Fig. 3). Finally, there are pairs of positive and negative peaks on either side of the propionic acid side chains of the haem group, showing that its inclination is becoming less steep in the liganded form (Fig. 2).

In the β-chains the entry of tyrosine HC2(145) into its pocket between helices F and H is blocked by the BME group, but the difference Fourier indicates a similar inward movement of helix F, leading to a narrowing of the pocket between it and helix H, as in the α-chain, evidently designed to expel the tyrosine if it were there.

The most prominent feature is a negative peak in the position of valine E11(67), showing the widening of the space between the porphyrin ring and helix E on ligand binding already referred to. There are also peaks near the haem group (when viewed as in Fig. 18 of refs. 4, 5) showing that its tilt becomes less steep in the liganded form, that is, its iron atom has moved away from valine E11.

The $\alpha_1\beta_2$ contact shows signs of strain as though on dissociation of ligand the residues were trying to move towards the deoxy conformation; that is, a set of positive and negative peaks which correspond to a movement towards the observer of the β_2 subunit in Fig. 2. It also looks as though the entry of the tyrosine HC2(140)α_1 into its pocket pressed on the indole ring of tryptophan C3(37)β_2, causing it to tilt over and to press on proline C2(36)β_2, and thus helping to push the β-chain in the required direction (see Fig. 15 of refs. 4, 5).

These results show that on binding of ligand to the α subunit, helix F moves so as to expel tyrosine HC2(140) from its pocket. A similar movement of helix F occurs in the β-chain. On removal of ligand, residues at the $\alpha_1\beta_2$ contact show signs of strain moving them towards the deoxy formation, even though the required sliding at the contact is inhibited by the BME.

I then examined the atomic models of oxy and deoxyhaemoglobin to see if the change in the width of the tyrosine pocket is detectable there, and found that, on going from deoxy to oxy, its width had shrunk by 1·3 Å in the α and by 2 Å in the β subunits. Model building shows that the tyrosines do not fit into the pockets of the oxy form without making short contacts with atoms of helices F and H.

The differences in quaternary structure are as previously described[23], with small shifts of not more than 1 Å at the pair of subunit contacts $\alpha_1\beta_1$ and $\alpha_2\beta_2$, and large relative shifts of up to 7 Å at the contacts $\alpha_1\beta_2$ and $\alpha_2\beta_1$. Apart from the salt-bridge just mentioned between histidine HC3(146)β_1 and lysine C5(40)α_2, a small increase in the number of van der Waals interactions seems to occur on oxygenation; the number of hydrogen bonds at either pair of contacts probably remains unchanged. Neither of the two forms contains any direct links between the two β-chains, but it will be shown in the following article that these are furnished in the red cell by 2,3-diphosphoglycerate.

At 5·5 Å resolution we had detected no changes in the tertiary structures of the individual chains. At 2·8 Å resolution various small shifts have become apparent, some distances between residues in neighbouring helices having changed by as much as 2–3 Å, which suggests that each subunit undergoes a small concerted change in tertiary structure. This possibility was first suggested by Dr A. D. McLachlan after he had built space filling models of myoglobin and of the two haemoglobin chains. He found the side chains in the interior of the myoglobin molecule to be tightly packed, which made the model rigid, while those in the haemoglobin subunits seem more loosely packed, giving the helices some freedom of movement. The observed changes will be described elsewhere.

Where is the force that changes the quaternary structure applied ? The evidence is overwhelmingly in favour of the contacts $\alpha_1\beta_2$. During the change of quaternary structure the contacts $\alpha_1\beta_1$ remain largely passive, whereas large movements occur at $\alpha_1\beta_2$. All but one of the mutations replacing residues at the $\alpha_1\beta_2$ contact diminish haem–haem interaction, whereas mutations at the $\alpha_1\beta_1$ contact do not. Nearly all residues at the $\alpha_1\beta_2$ contact are invariant throughout the vertebrates (except lamprey), while many of those at the $\alpha_1\beta_1$ contact are variable. The BME difference Fourier shows the beginnings of the changes that would make the contact jump from the oxy to the deoxy conformation.

The contact $\alpha_1\beta_2$ is dovetailed, so that the CD region of one chain fits into the FG region of the other (see Fig. 8 of ref. 1 or Fig. 14 of refs. 4, 5). During the change of quaternary structure the two subunits rotate relative to each other so that the dovetailing of CDβ with FGα remains much the same, whereas that of CDα with FGβ changes. The change works like this: in oxyhaemoglobin a knob consisting of the side chain of threonine C3(38)α fits into a notch made up of the main chain of valine FG5(98)β. In deoxyhaemoglobin that same notch is occupied by the side chain of threonine C6(41)α —that is, the one protruding from the next turn of the C helix. At the same time the hydrogen bond linking aspartate G1(94)α to asparagine G4(102)β in oxyhaemoglobin is replaced by a hydrogen bond between tyrosine C7(42)α and aspartate G1(99)β in deoxyhaemoglobin[3]. If there were an intermediate quaternary structure, there could be no dovetailing, because knobs would fit against knobs; nor could any hydrogen bond be made to stabilize it. On stereochemical grounds its existence therefore seems unlikely. Another type of intermediate would be one where the $\alpha_1\beta_2$ contact, say, has clicked to the oxy conformation and the $\alpha_2\beta_1$ contact has remained in the deoxy conformation. In such an asymmetric intermediate all four contacts would be severely stressed, which would make it very unstable. But in view of the high speed of the reaction of haemoglobin with oxygen the occurrence of such an intermediate cannot be excluded.

Spectroscopic evidence favours the existence of an intermediate, but not necessarily one with a quaternary structure different from the oxy and deoxy forms. McConnell and his group find the ESR spectra of spin-labelled oxy and deoxyhaemoglobin to be markedly different[24]. Their spin label is attached to cysteine F9(93)β which lies near the tyrosine pocket and the $\alpha_1\beta_2$ contact, so that the label would sense changes in the conformation of the β and the α-chains as well as shifts at that contact (Fig. 2). If haemoglobin existed in only two alternative conformations, then the ESR spectra at successive stages of oxygenation should exhibit common isosbestic points. Because this is not the case with one of the labels used, the authors argue that there must be an intermediate structure. I shall suggest what type of structure this might be.

We must now consider the tertiary structure of the individual subunits which changes on uptake of ligands, as the BME experiment has proved. On uptake of oxygen, the tertiary structures of the individual subunits click to the oxy conformation, but the quaternary structure may remain in the deoxy conformation until several of the subunits have reacted with oxygen; consequently, subunits in the oxy conformation will be constrained in the quaternary structure of deoxy, or vice versa. Will these constrained subunits take up an intermediate conformation ?

The BME difference Fourier should tell, because it shows deoxy subunits locked in the quaternary structure of oxy. When I compared that difference Fourier with the actual differences between the native oxy and deoxy structures, I found it contained many, but not all, of the expected pairs of positive and negative peaks. This suggests but does not prove intermediate tertiary structures. Direct comparisons of the oxy and deoxy structures are still at too early a stage to judge whether intermediate tertiary structures are probable or not on stereochemical grounds. So the X-ray evidence is not yet clear.

Ogawa and Shulman have examined NMR spectra of mixed hybrids in which one pair of chains is kept locked in the liganded form as the cyanomet derivative, and the other pair is free to be oxygenated or deoxygenated. They find that deoxygenation of $(\alpha O_2\beta^+CN)_2$ in phosphate buffer did not show any effect on the paramagnetically shifted proton resonances of the β-haem and its immediate environment, while marked changes can occur in the spectrum of the α-haem on deoxygenation of $(\alpha^+CN\beta O_2)_2$. They interpret this result to mean that the former derivative remains in the quaternary oxy structure throughout

the reaction, while the latter may change to the quaternary deoxy structure, where the liganded α-chains are subject to strains extending from the subunit boundaries right to the haem groups[25]. The magnitude of these strains seems to be too small, however, to contribute significantly to the internation energy between the haems.

In my proposed mechanism I shall assume that each subunit can take up only two alternative stable tertiary structures, the deoxy and the liganded form. But these structures may be subject to strains when subunits are confined in the "wrong" quaternary structure.

Mechanism of the Conformational Change

I shall discuss first the conformation changes in the individual subunits that follow the binding of ligand; next, the change in quaternary structure caused by them; and finally, the probable order of the steps of the reaction with ligands.

What is the trigger that sets the conformational changes in motion? The distances between the haem groups are far too large (25–37 Å) for electromagnetic interactions to be effective, which suggests that the trigger is stereochemical. It was not clear, however, whether the changes are triggered by some deformation of the haem group or by the ligand prising the haem pocket apart. Consider first the α subunit. Because a ligand finds ample room in its haem pocket in both the oxy and the deoxy form, and the width of the pocket does not change significantly, the latter mechanism can be safely excluded. We have seen that the transition from deoxy to oxyhaemoglobin involves a movement of the proximal histidine towards the plane of the porphyrin amounting to 0·75–0·95 Å. The transition from deoxy to acid methaemoglobin involves a smaller movement, of 0·45–0·65 Å, in the same direction. Movements of this magnitude should be sufficient to set the changes in tertiary structure of the reacting subunit in motion, because the iron atom is rigidly linked to histidine F8 and the porphyrin is in contact with about sixty atoms of the globin which is flexible and can give. The way it gives can be seen in the difference electron density maps of BME deoxy versus methaemoglobin, which showed, among other things, that helix F moves towards the centre of the molecule and expels tyrosine HC2(140) from its pocket between helices F and H (Fig. 3). The expelled tyrosine must pull arginine HC3(141) with it, thus breaking its salt-bridges with the opposite α subunit and releasing Bohr protons (see Fig. 2 of the following article).

We may now turn to the β subunits. Here the trigger is clearly composite. Before the ligand can reach the iron atom, it must prise open the haem pocket (or rather, wait until thermal vibrations provide the activation energy needed to open it); reaction with the haem then moves the iron into the plane of the porphyrin ring. The accompanying changes in tertiary structure have one feature in common with those observed in the α-chain: helix F moves towards the centre of the molecule, narrowing the pocket between it and helix F and presumably expelling tyrosine HC2(145). The validity of this vital point is supported by much indirect evidence concerning the inhibitory effects of reagents which either remove that tyrosine or prevent its entry into the pocket, but it will have to be checked by direct experiment. The expelled tyrosine must pull histidine HC3(146) with it and break its salt-bridge to aspartate FG1(94) (see Fig. 1 of the following article). The salt-bridge to lysine C5(40)α may or may not have been broken already before the β-chain could have reacted with a ligand.

We shall now examine the likely order of the steps involved in the reaction with ligands and the ensuing conformational changes (Fig. 4). In deoxyhaemoglobin, the α subunits have room for ligands, but the β subunits do not, so that the α subunits are likely to react first. The argument is not rigorous, for relative rates of combination with oxygen of the different subunits must depend on the total activation energy needed to change their tertiary structure from the deoxy to the oxy state—which cannot be readily predicted. Low ligand affinity of the β subunits in the deoxy tetramer is not supported by kinetic data, but further work is needed to test this point. In any case the cooperative mechanism I propose would not be affected if the order of steps turned out to be the reverse of the one given below or if it proved to be random.

Reaction of $Fe\alpha_1$ with oxygen causes tyrosine HC2(140)α_1 to be expelled from its pocket and the links between arginine HC3(141)α_1 and the α_2 subunit to be broken, with the release of Bohr protons. $Fe\alpha_2$ reacts next, followed by the expulsion of its tyrosine and the rupture of the links between the C-terminal arginine and the α_1 subunit, with further release of Bohr protons. By now four of the six salt-bridges constraining the deoxyhaemoglobin tetramer will have been broken, with a resulting change in the allosteric equilibrium constant in favour of the quaternary oxy structure. For illustrative purposes I shall assume that this is of a magnitude sufficient to change the quaternary structure to the oxy form. (In fact, the change might occur at any stage in the reaction depending on external factors such as *p*H and the concentrations of CO_2 and organic phosphates.) The $\alpha_1\beta_2$ and the $\alpha_2\beta_1$ contacts now give way and the tetramer clicks to the oxy form, breaking the remainder of the constraining salt-bridges, that is, the ones between lysines C5(40)α and histidine HC3(146)β, and the ones between DPG and the two β subunits. This step leads to the liberation of DPG but does not release Bohr protons.

We now have an intermediate with the quaternary structure of oxyhaemoglobin; the two-fold symmetry of the molecule is conserved; the haem and its immediate environment in the α subunit have the oxy conformation, and those in the β-chains have the (strained) deoxy conformation; that is, the tyrosines HC2(145)β are still in their pockets, keeping the ligand sites obstructed by valine E11(67). A structure of this type could be the intermediate sensed by McConnell's spin label. The change of quaternary structure has halved the activation energy needed to expel the tyrosines HC3(146)β from their pockets, because it has broken the salt-bridges between the C-terminal histidines and the α subunits, so that only the internal salt-bridges between the C-terminal histidines and aspartates of the same β-chain now remain to hold the tyrosines in place, with a resulting increase in oxygen affinity (see Fig. 1 of the following article).

The iron atoms of the β-chains now react with ligand, each reaction being accompanied by the expulsion of a tyrosine and the rupture of one of the salt-bridges just mentioned, causing release of the last Bohr protons.

The essence of the mechanism may be summarized as follows. The haem group is so constructed that it amplifies a small change in atomic radius, undergone by the iron atom in the transition from the high spin to the low spin state, into a large movement of the haem-linked histidine relative to the porphyrin ring. This movement, and the widening of the haem pocket required in the β chain, triggers small changes in the tertiary structure of the reacting subunits, which include a movement of helix F towards helix H and the centre of the molecule. Exactly how leverage from the iron atoms pushes helix F in that direction is not yet clear, but this movement can be observed to narrow the pocket between helices F and H so that the penultimate tyrosine is expelled. The expelled tyrosine pulls the C-terminal residue with it, rupturing the salt-bridges that had held the reacting subunit to its neighbours in the deoxy tetramer. The rupture of each salt-bridge removes one of the constraints holding the molecule in the deoxy conformation and tips the equilibrium between the two alternative quaternary structures some way in favour of the oxy conformation. In this conformation the oxygen affinity is raised because the subunits are no longer constrained by the salt-bridges to

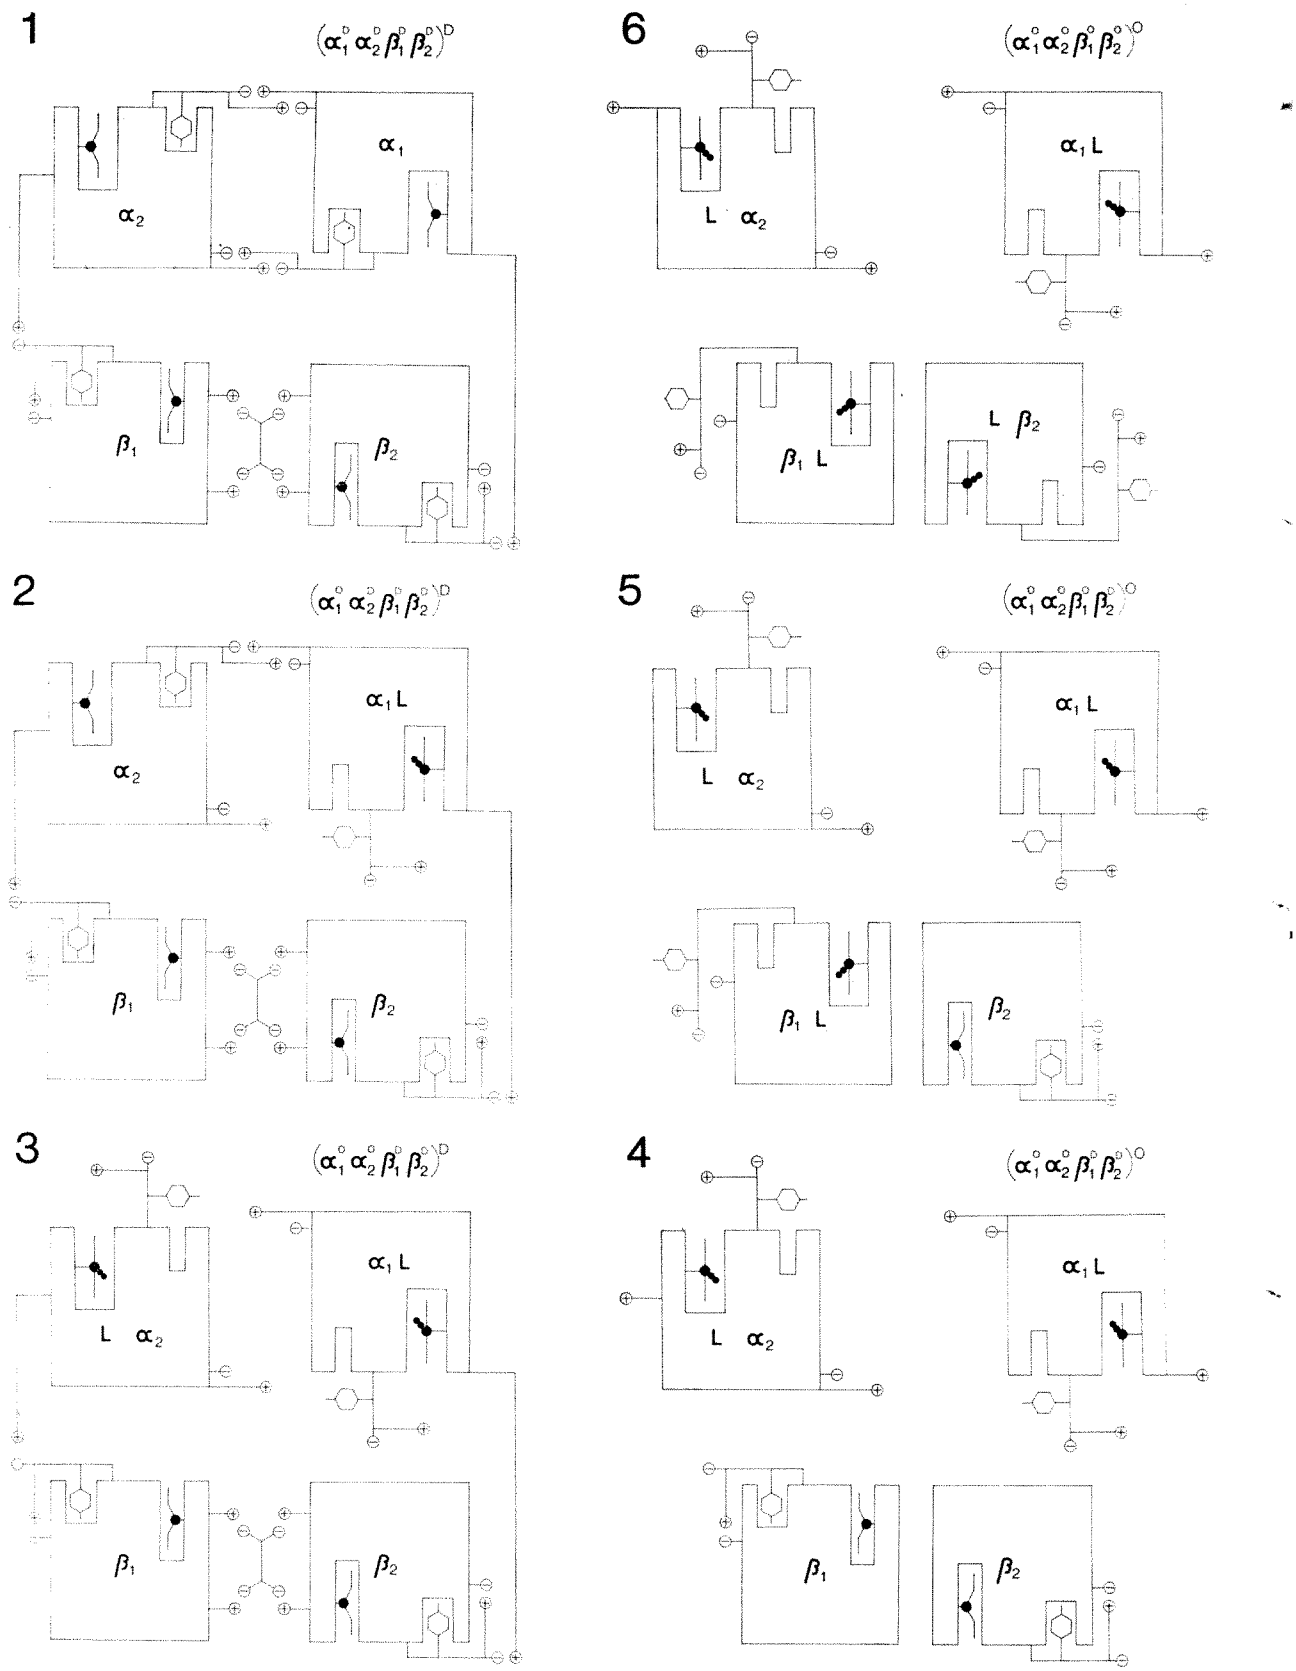

Fig. 4. Diagrammatic sketch showing one possible sequence of steps in the reaction of haemoglobin with oxygen. **1**, Deoxyhaemoglobin with all salt-bridges intact and with one molecule of DPG clamped between the two β-chains. At steps 1–2 and 2–3, the α-chains are oxygenated. The tyrosine pockets are narrowed, the tyrosines expelled and the salt-bridges with the partner α-chains are broken. In step 3–4 the quaternary structure clicks to the oxy form, accompanied by the expulsion of DPG, and the breakage of the salt-bridges between subunits α_1–β_2 and α_2–β_1. Note that the internal salt-bridges of the β-chains are still intact and their haem pockets too narrow to admit ligands. At steps 4–5 and 5–6, the β subunits react in turn, accompanied by widening of the haem pockets, narrowing of the tyrosine pockets and rupture of the internal salt-bridges from the C-terminal histidines to aspartates 94. Note that the change of quaternary structure could in fact take place at any stage of the reaction, and the cooperative mechanism is independent of the sequence in which the individual subunits react.

maintain the tertiary deoxy structure. The following article shows that it also leads to the liberation of Bohr protons, in agreement with the finding that their release is exactly proportional to the amount of oxygen taken up, and that the two reactions are synchronous[26,27]. I have suggested that the subunits react in the order α_1, α_2, β_1, β_2, but this is not certain and my cooperative mechanism would work equally well in whichever sequence the individual subunits reacted.

In haemoglobins where one pair of subunits, either α or β, is unreactive, the other, reactive, pair may or may not be able to actuate the change in quaternary structure: this will depend on the conformation of the unreactive pair and other factors. The literature contains instances where reaction with ligands of either the α or the β subunits alone apparently can or cannot change the quaternary structure of the tetramer. The reasons are not clear without X-ray analysis of each separate case.

Nature of Interaction Energy

Where in this large molecule should one look for that energy? Conceivably the reaction of one haem with oxygen might exercise a direct steric effect which raises the oxygen affinity of its neighbours. Nuclear magnetic resonance spectra offer an extremely sensitive probe for small changes in the environment of one haem caused by the binding of oxygen to another. Studies with mixed hybrids show no evidence that such changes occur unless there is a change in quaternary structure, which led Shulman and his colleagues to suggest that the energy of interaction arises at the boundaries between the subunits[25,36].

Bolton and Perutz found fewer van der Waals interactions at contacts between the α and β subunits in deoxy than in oxyhaemoglobin, and about the same number of hydrogen bonds. Consequently, neither of these is likely to provide the stabilizing interaction that constrains the subunits in the quaternary deoxy form. The most obvious constraints are the six salt-bridges made by the C-terminal residues which link the contacts $\alpha_1\alpha_2$, $\alpha_1\beta_2$ and $\alpha_2\beta_1$. This is borne out by the discovery that enzymatic removal of the four C-terminal residues makes the quaternary deoxy structure unstable and inhibits haem–haem interaction. The bond energy per salt-bridge may reasonably be estimated as 1–2 kcal/mole. For six salt-bridges this gives a total interaction energy of between 6 and 12 kcal/mole of haemoglobin, that is, a value of the same order as the observed interaction energy of 12 kcal/mole. If it is only the salt-bridges which constrain the deoxy tetramer, then part of the energy released by the reaction of the haem groups with oxygen must be expended to break them. The change in conformation of the haem group that leads to the expulsion of the tyrosine provides the required stereochemical mechanism.

Do the changes in the free energy of the subunit contacts in going from the deoxy to the oxy tetramer account for all the interaction energy or for only part of it? This question is important for an understanding of the mechanism, because the answer should tell us whether direct interaction occurs between the β-chains, say, if they react with oxygen after the tetramer has clicked to the oxy conformation. We have seen that haem–haem interaction is absent when the transition to the deoxy structure is inhibited as in BME haemoglobin and haemoglobin from which the C-terminal residues have been removed. Another system is haemoglobin M Iwate (His F8(87)$\alpha\rightarrow$Tyr)[28] where the α-chains are unreactive and the tetramer is locked in the deoxy conformation[29]. The β-chains have a low affinity for oxygen, and their reaction with oxygen produces no haem–haem interaction or Bohr effect, showing again that these effects are absent without a change of quaternary structure. The biochemical data on other systems offer no firm evidence that haem–haem interaction ever occurs without a change of quaternary structure, which suggests that the changes in the free energy of the subunit contacts do seem to account for all the energy of interaction. On the other hand, the abnormal haemoglobins include unexplained instances of very weak haem–haem interaction where the change of quaternary structure does take place.

Dimers or Tetramers as the Functional Units

It has been suggested that $\alpha\beta$ dimers exhibit all the cooperative effects characteristic of the haemoglobin tetramer[32]. These dimers have the structure $\alpha_1\beta_1$, so that the contact $\alpha_1\beta_2$ remains open. There is no reason why an oxyhaemoglobin dimer should not function as well as a tetramer, for the terminal residues are free, and the subunits are not constrained by the $\alpha_1\beta_2$ contact. On the other hand, the deoxy form can exhibit a low oxygen affinity only in the tetrameric form, for dissociation into dimers of whatever type would remove the constraining salt-bridges on which the energy of interaction depends. This conclusion may seem to contradict the finding that haemoglobin solutions show full cooperativity in conditions where the haemoglobin is apparently split into $\alpha\beta$ dimers. Kellett, Midgarden and Schachman, however, have recently discovered that only the liganded form of haemoglobin is split, whereas the deoxy form remains tetrameric in all conditions formerly believed to produce dimers (see ref. 35). They estimate the dissociation constants of the two forms to differ by a factor of at least 10^4. For comparison, the stabilizing free energy of either 6 or 12 kcalories for the extra six salt-bridges in the deoxy form would lower the dissociation constant by a factor of 5×10^5 and 2×10^9 respectively—sufficient to make dissociation of the deoxy form unobservable. This suggests that all cooperative effects observed on binding of haem ligands take place in the tetrameric molecule while it has the quaternary deoxy structure; splitting into dimers may occur at very low haemoglobin concentrations or at high concentrations of neutral electrolytes, but only after the salt-bridges have been broken, when normally the quaternary structure would click to the oxy conformation.

Implications for Allostery

For purposes of comparison haemoglobin may be regarded as an enzyme made up of two different pairs of subunits with oxygen as the substrate, haem as the coenzyme, and H^+ and DPG as the allosteric effectors. Let α and β denote the subunits in the free conformation and α^S and β^S their conformation when substrate is bound. $[\ ]^T$ represents the unreactive and $[\ ]^R$ the reactive quaternary structure. Then for illustrative purposes, the reaction scheme of Fig. 4 can be rewritten as

$$\left[\alpha_2\beta_2\right]^T \underset{+2S}{\rightleftharpoons} \left[\alpha_2^S\beta_2\right]^T \rightleftharpoons \left[\alpha_2^S\beta_2\right]^R \underset{+2S}{\rightleftharpoons} \left[\alpha_2^S\beta_2^S\right]^R$$

The mechanism of haem–haem interaction contains features of several of the theories that have been advanced to account for interaction between ligand sites in enzymes. Monod's model postulates "the existence of only two (or at least two) stable states that are accessible to allosteric oligomers. These states differ by the distribution and/or energy of intersubunit bonds, and therefore also by the conformational constraints imposed on the subunits. As a result, the affinity of one (or several) of the stereospecific sites is altered when a transition occurs to the other state"[9]. These words ring prophetically if we look at the mechanism in terms of the quaternary structure.

Monod *et al.* assumed all the subunits in the quaternary T-state to be in the unreactive and those in the quaternary R-state in the reactive form, no matter whether they were liganded or not. In their discussion they envisaged the possibility that this assumption might prove too

simple and this is indeed the case. The haemoglobin subunits change their tertiary structure in response, not to the change in quaternary structure, but to the binding of ligand, as predicted by Koshland's sequential model[34]. Yet Koshland's model implies that the change in tertiary structure of each subunit directly affects the ligand affinity of its neighbours, and there is no evidence of this happening in haemoglobin. Rather, all—or nearly all—the interaction energy arises through the step by step release of the constraints on the unreactive quaternary structure, which changes the equilibrium in favour of the reactive quaternary structure and diminishes the work required to change the tertiary structure of each subunit from the unreactive to the reactive form (see Fig. 6 of the following article).

In Koshland's terms[35], the change in tertiary structure of the α subunits would be caused by induced fit in response to a change in conformation of the coenzyme on reacting with substrate; that of the β subunits in response to both the change of conformation of the coenzyme and the steric adaptation of the active site to the substrate.

How would allosteric effectors influence the reactivity? In haemoglobin both hydrogen ions and DPG lower the reactivity; the former strengthen the salt-bridges constraining the inactive or T state by increasing the fraction of molecules carrying positive charges on one α amino and two imidazole groups (see the following article); DPG may increase the free energy of interaction by introducing additional salt-bridges specific for the T-state, to which it is stereochemically complementary but has either no affinity or a lower one for the R-state.

The cooperative mechanism outlined here explains most of the important properties of haemoglobin, even though stereochemical details are still lacking. It is of a kind that could not have been guessed without knowing the structure of the two forms in atomic detail and without further information which the inhibited BME-haemoglobin provided. Even then it could be worked out only by combining the structural information with many other results.

It is remarkable that there should be such an exceedingly complex, subtle and elegant instrument of respiratory transport, exploiting a difference in atomic radius of 13 per cent between the covalent and ionic forms of iron.

I thank Drs F. H. C. Crick, A. D. McLachlan, R. J. P. Williams and Mrs J. M. Baldwin for discussing the mechanism, Dr J. Greer for calculating difference Fouriers, Mr Lawrence Boxt for building a model of haemin chloride, and Miss Valerie Coulson and Miss Susan Crane for technical assistance.

The Bohr Effect and Combination with Organic Phosphates

LIKE haem–haem interaction, the Bohr effect results from the change in structure which the haemoglobin molecule undergoes on combination with oxygen (see preceding article). The stereochemical consequences of this change have been studied in atomic models derived from electron density maps of haemoglobin at high resolution[1–3]. The models show that the change in structure alters the environment of three pairs of weak bases so that they would tend to take up hydrogen ions on discharge of oxygen. The α-amino groups of valine 1α and the imidazole groups of histidines 146β are free in oxyhaemoglobin, but come close to carboxyl groups in the deoxy form[4,5]; the imidazole groups of histidines 122α approach guanidinium groups in the oxy and carboxyl groups in the deoxy form. A survey of all other ionizable groups in the structure of oxy and deoxyhaemoglobins suggests that none of them are likely to change their state of ionization significantly on binding of oxygen near neutral *p*H.

Early Ideas concerning the Bohr Effect

The Bohr effect is produced on combination of O_2, CO or NO with the ferrous form of haemoglobin (deoxyhaemoglobin) or on oxidation of deoxyhaemoglobin to the ferric form (methaemoglobin) but not on combination of methaemoglobin with ligands. In other words, it is observed only in those reactions involving a change in quaternary structure from the deoxy form, in which the iron atoms are five coordinated, to the oxy or liganded form in which they are six coordinated. It is observable either as a change in *p*H on binding of haem ligands or as a change in affinity of the haem iron to ligands as a function of *p*H. At a *p*H above 6·0 haemoglobin takes up protons on release of haem ligands; this is known as the alkaline Bohr effect and reaches its maximum of 0·7 protons per haem ligands at physiological *p*H.

The alkaline Bohr effect has a two-fold function. On liberation of oxygen haemoglobin neutralizes the protons released in the blood by the uptake of CO_2, thereby facilitating its transport from the tissues to the lungs. Acid *p*H lowers the affinity of haemoglobin for haem ligands, which helps the release of oxygen in tissues rendered acid by bicarbonate and lactic acid. Below *p*H 6·0 the Bohr effect is reversed, protons being liberated on release of haem ligands. Because *p*Hs below 6 are not likely to occur *in vivo*, however, this reverse, or acid, Bohr effect may have no physiological significance.

Wyman showed that the Bohr effect could be attributed to ionizable amino-acid side chains with a pK close to 7·0 which might either release or take up H^+ as a result of oxygenation of the iron atoms[6]. He determined the heat of dissociation of the Bohr protons as 6,500 calories per equivalent, and showed that this is characteristic for histidine. Further analysis based on the variation of proton released or taken up as a function of pH on oxygenation led him to suggest that each haem interacts with two histidines, one on each side of the haem, a scheme that had already been proposed by Conant[7]. To the histidine responsible for the alkaline Bohr effect he ascribed a pK of 7·8 in deoxy changing to 6·2 in oxyhaemoglobin; to that responsible for the acid Bohr effect a pK of 4·9 in deoxy and 5·7 in oxyhaemoglobin. Coryell and Pauling arrived at the same conclusion on the basis of magnetic susceptibility measurements and introduced the term "haem-linked acid groups"[8]. The environment of the haems first predicted by Conant was verified when the structure of myoglobin was solved, but the mystery of the Bohr effect was deepened because the tertiary structures of myoglobin and of each of the haemoglobin chains proved closely similar, yet myoglobin was known to show no Bohr effect[9]. This meant that the haem-linked histidines could not be responsible for it and that the term "haem-linked acid groups" was a misnomer. When the uptake of haem ligands was found to be accompanied by a marked change in quaternary structure[10] it seemed possible that this might alter the environment of ionizable groups other than the haem-linked ones in the required way. We were able to identify two of the groups concerned[4,5], but it took electron density maps of both the oxy and deoxy forms at high resolution before we could see all the groups and determine the exact stereochemical mechanism which changes their state of ionization in the two forms of haemoglobin.

C-terminal Residues

In the liganded form of haemoglobin the C-terminal arginines of the α-chains and histidines of the β-chains rotate freely. The penultimate tyrosines seem to rotate freely for most of the time; they spend the remainder in a slot between helices F and H. Several pieces of evidence support this picture. The C-terminal residues are invisible in the electron density maps of oxyhaemoglobins; only traces of the penultimate tyrosines are to be seen. Because model building showed various ways in which the C-terminal groups could be held down by salt-bridges[1], I thought at first that this freedom might be an artefact, arising from the weakening of salt-bridges by the 2 M ammonium sulphate solution in which the crystals were suspended.

Fortunately, crystals of methaemoglobin can be prepared free of salt; these are isomorphous with those of oxyhaemoglobin precipitated by salt. X-ray reflexions of the salt-free crystals were collected on a diffractometer to a resolution of 3·5 Å and a difference Fourier synthesis of salt-free minus salty haemoglobin was calculated. If the C-terminal residues had been held down in fixed positions in salt-free crystals they should have shown up there as positive peaks, but there was no sign of these. In fact, the difference map was featureless, except for a negative peak on the dyad axis, possibly representing a negative ion trapped in the internal cavity. I had to conclude therefore that the C-termini were equally free in the absence of salt.

Other evidence supporting freedom of rotation of the penultimate tyrosines of the β-chains comes from work on a haemoglobin carrying spin labels at the reactive SH-groups 93β (ref. 11). The spin label oscillates rapidly between two alternative conformations, in one of which it is free and in the other immobilized. X-ray analysis showed that in the immobilized conformation the spin label takes the place of the penultimate tyrosine in the pocket between helices F and H, implying that the tyrosine itself oscillates rapidly between a free and an immobilized position and that these oscillations are synchronized with those of the spin label[12].

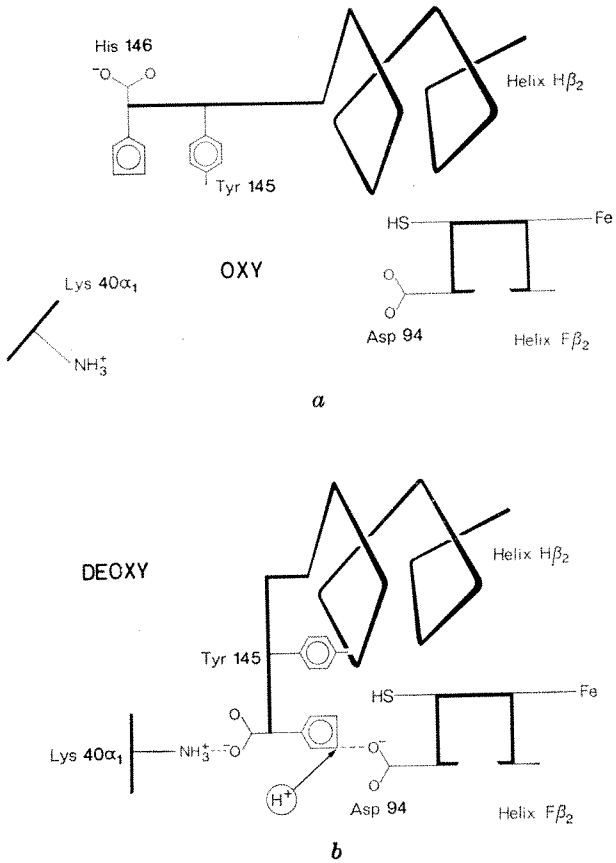
When we proposed that the contribution of the β-chains to the alkaline Bohr effect arose through the freedom of the C-terminal histidines in oxy and the linkage of their imidazoles to aspartates 94 of the same β-chains in deoxyhaemoglobin[4], we were unable to explain why this link was maintained only in the deoxy form, even though no steric obstacles appeared to stand in its way in the oxy form. The expulsion of the penultimate tyrosines already described and the existence of an unsuspected salt-bridge of lysine C5(40)α with histidine HC3(146)β now provide the explanation. Fig. 1*a* shows the freedom of the C-terminal residues in oxyhaemoglobin.

Consider now the transition to the deoxy structure. In oxyhaemoglobin lysine C5(40)α_1 thrusts its side chain far out into the solution. During deoxygenation the α_1-chain turns relative to the β_2-chain by 13·5°. The ε-amino group of lysine C5(40)α_1, being furthest removed from the axis of rotation of the α_1-chain, is shifted by 7 Å into the $\alpha_1\beta_2$ contact, where it can form a salt-bridge with the C-terminal carboxyl group of the β_2-chain. This salt-bridge keeps tyrosine 145β_2 fixed in its pocket between helices F and Hβ_2 and allows the further salt-bridge between the imidazole of histidine 146β_2 and aspartate 94β_2 to be formed (Fig. 1*b*). The electron density maps of deoxyhaemoglobin at high resolution show the interatomic distances between the acidic and basic groups to have the correct length (~3 Å) for the salt-bridges[2,3].

These findings suggest that histidine HC3(146)β contributes to the Bohr effect by a change in pK of its imidazole, arising through the shift from its free position in oxyhaemoglobin to its fixed position in deoxyhaemoglobin. In oxyhaemoglobin the pK of the imidazole must be slightly raised by the negative field of the histidine's own free carboxyl group. In deoxyhaemoglobin the field of the C-terminal carboxyl group is compensated by lysine 40α, but the imidazole becomes linked to aspartate 94β. This apparently produces a much larger increase in pK than the more distant interaction with its own carboxyl group in oxyhaemoglobin. We do not know of any comparable model situations which would allow us actually to predict the changes in pK, but it should soon be possible to titrate the histidines directly by NMR spectroscopy. The recently observed absence of half the alkaline Bohr effect in des-histidine(146)-haemoglobin confirms our scheme[13].

The first hint of the involvement of the C-terminal arginines of the α-chains was the observation that enzymatic removal diminished the alkaline Bohr effect[14], which has recently been confirmed[13]. This leaves a Hill's coefficient of 1·8, indicating that the change of quaternary structure still accompanies the reaction with oxygen[13]. Because the pKs of guanidinium groups and α-carboxyl groups are 12·5 and 3·4 respectively, neither group could itself lose or gain protons at neutral pH, which implies that their contribution must arise from interaction with other ionizable groups. The next advance came with the discovery that blocking of the α-amino groups of valine 1α with cyanate inhibited about one-quarter of the Bohr effect[5].

The electron density maps of oxyhaemoglobin at 2·8 Å resolution showed the valines 1α to be free, and the maps of deoxyhaemoglobin at 5·5 Å resolution showed bridges connecting the C-terminus of one α-chain with the N-terminus of its partner chain. These observations led us to propose that the pKs of the α-amino groups are normal in oxyhaemoglobin, but are raised in the deoxy form through linkage of the α-amino groups of one chain to the α-carboxyl groups of their partner chains. At that stage our hypothesis could not be proved, however, and in any case it was uncertain whether it could account for the entire share contributed to the Bohr effect by the α-chains. Our new results confirm the interaction between these



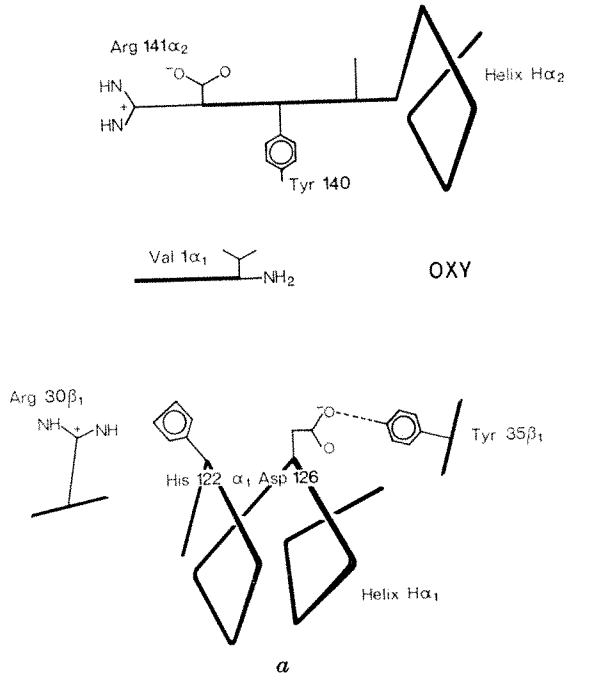


Fig. 1. Change in conformation of C-terminal residues of β-chain on deoxygenation: *a*, in oxyhaemoglobin histidines 146β_2, aspartates 94β_2 and lysine 40α_1 are free and far from each other. Access to the SH groups is free; *b*, in deoxyhaemoglobin, formation of a salt-bridge between aspartate 94 and the imidazole of histidine 146 leads to ionization of the latter. The salt-bridge is cemented by a further bridge between the C-terminal carboxyl of the β_2-chain and lysine 40α_1. Access to the SH groups is restricted.

terminal residues, and suggest the possibility of a further residue contributing to the Bohr effect.

The electron density maps of deoxyhaemoglobin at high resolution show that the C-terminal arginine of each α-chain forms two salt-bridges with its partner chain[2,3]. One bridge extends from the guanidinium group α_2 to aspartate H9(126)α_1 and the other from the α-carboxyl group α_2 to a cluster of three ionizable groups composed of valine NAl(1), aspartate A4(6) and lysine H10(127)α_1 (Figs. 2 and 3). The precise constellation of this cluster is not resolved but can be guessed with the help of stereochemical rules. Aspartate 6 is bound only to lysine 127. The α-carboxyl group of arginine 141 must have one of its oxygens pointing towards valine 1 rather than towards lysine 127, for otherwise the O–N distance would be too short. The electron density peak for valine 1 does not resolve its isopropyl side chain from its α-amino group, which leaves one free to rotate this residue as desired. On electrostatic grounds, however, the α-amino rather than the isopropyl group would tend to face the α-carboxyl group, resulting in the arrangement of Fig. 3. The proximity of the positively charged lysine 127 would weaken the effect of the negatively charged carboxyl on the *pK* of the α-amino group of valine 1, even though the lysine's charge is compensated by that of aspartate 6. Perhaps for this reason, the ionization of the α-amino groups may be only partial, so that it may not account for the α-chain's entire contribution to the Bohr effect.

We come now to a second possible contribution from the α-chains. Formation of links extending from the guanidinium group of the arginine HC3(141)α_2 to aspartate H9(126)α_1 causes a rearrangement in a cluster of polar groups which includes histidines H5(122)α_1. In oxyhaemoglobin the centre of the imidazole of histidine H5(122)α_1 lies within 5·5 Å of the guanidinium group of arginine B12(30)β_1 and is separated by 4·5 Å from the centre of the carboxyl group of aspartate H9(126)α_1. In deoxyhaemoglobin these distances are altered to 7·5 Å and 3 Å respectively (Fig. 4). This shift would suggest that the *pK* of histidine 122 is lowered by the proximity of a positive charge in oxy and raised by the proximity of a negative one in deoxyhaemoglobin. On oxygenation of

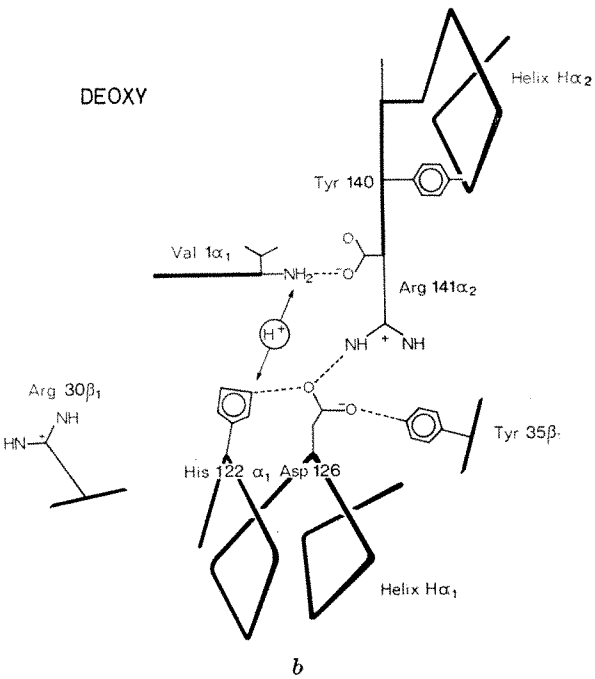

Fig. 2. Change in conformation of terminal regions of the α-chain on deoxygenation: *a*, in oxyhaemoglobin valine 1α_1 and arginine 141α_2 are free, histidine 122α_1 is close to arginine 30β_1, and aspartate 122α_1 is hydrogen bonded only to tyrosine 35β_1; *b*, in deoxyhaemoglobin valine 1α_1 is in contact with the carboxyl group of arginine 141α_2. Aspartate 126α_1 forms close contacts with histidine 122α_1, tyrosine 35β_1 and arginine 30α_2.

Feα, the expulsion of tyrosine HC2(140) would rupture the links of the C-terminal arginines with valine 1 and aspartate H9. Clearly, this would liberate the Bohr protons bound to the α-amino groups of valine 1, but it is not yet clear why this would also affect the conformation of histidine H5 relative to its two neighbours. Their movements seem to depend on the change in quaternary structure.

It may be hard to test the part played by histidine 122α chemically unless a mutant can be found in which it is replaced by a neutral residue. Similarly the relative contributions of valine 1α and histidine 122α may prove difficult to assess exactly unless at least one of these groups can be titrated directly.

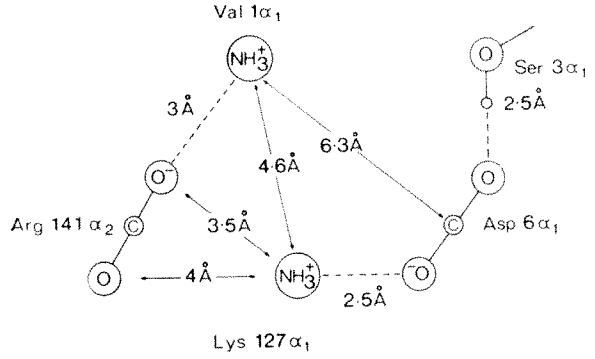

Fig. 3. Distances between members of the cluster of ionizable groups near valine 1α in deoxyhaemoglobin.

There are no changes in the conformation of the haem-linked histidines which would lead one to expect a change in their *pK*s. The proximal histidines F9 are linked to iron and would not be ionized; a contribution from the distal histidines is excluded by the presence of a full Bohr effect in haemoglobin Zürich in which histidine E7β is exchanged for an arginine[15]. A survey of all the other ionizable groups in oxy and deoxyhaemoglobin shows that most of the salt-bridges in the molecule are left undisturbed by the reaction of the haem group with ligands; the few that are disturbed involve ionizable groups with *pK*s far outside the range of physiological *p*H. Small changes in the general pattern of ionizable groups on the surface of the haemoglobin molecule do occur as a consequence of the change in quaternary structure that accompanies oxygenation. Some attempts are being made to use these as the basis for the interpretation of the Bohr effect, but theoretical reasons suggest that their contribution is small and experimental evidence confirms this[13]. We therefore conclude that no groups other than the ones described here contribute significantly to the alkaline Bohr effect.

The Acid Bohr Effect

The acid Bohr effect is observed at *p*H 6·0 and requires ionizable groups that change their *pK* from about 5·7 to 4·9 in going from oxy to deoxyhaemoglobin[6]. I could not find any groups that change their environment in the way required, however, and this made me wonder if there was not a different explanation. Horse oxyhaemoglobin crystals undergo a drastic lattice change at *p*H 5·9, the monoclinic angle decreasing from 111° to 98° (ref. 16). Patterson projections indicated at first that this lattice transition left the internal structure of the haemoglobin molecules unaltered[17], but isomorphous replacement with paramercuribenzoate showed that this was not true: a difference Patterson proved that the lattice transition was accompanied by a reduction of the distance between the reactive cysteines from 30 Å to 25 Å (ref. 18). (On deoxygenation this distance increases from 30 Å to 37 Å; that is, the changes are in the opposite direction.) Such a

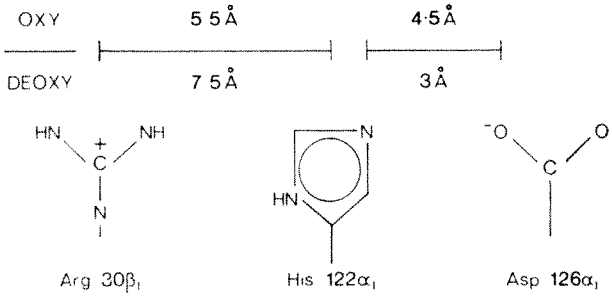

Fig. 4. Distances between histidine 122α and its neighbours in oxy and deoxyhaemoglobin.

reduction cannot occur without a change in quaternary structure which would affect the oxy and deoxy forms differently. I suggest that this is the cause of the acid Bohr effect: its details remain to be investigated. Incidentally, there is a further lattice change below *p*H 5·4, with a reduction of the angle from 98° to 85°, which may be the expression of a further change in quaternary structure[16].

SH Groups, the Spin Label, Invariant Residues

The reactivity of the SH groups at cysteine 93 increases in going from the deoxy to the oxy form and is linearly proportional to the degree of oxygenation[19]. This is readily accounted for by the changed conformation of the C-terminal histidines. In the oxy form they leave the SH groups accessible, while in the deoxy form they restrict access to it (Fig. 2). Oxygenation of each β-chain is accompanied by expulsion of tyrosine HC2 and the rupture of the restricting salt-bridges, thus accounting for the linear relationship between the two phenomena.

A similar mechanism accounts for the changed immobilization of the spin label attached to cysteine 93β. In deoxyhaemoglobin the tyrosine pocket is occupied, so that the spin label is free. In oxyhaemoglobin the tyrosine pocket is open, for part of the time, so that the spin label can be immobilized there. The transition from the free to the immobilized conformation is therefore proportional to the number of β chains which have taken up oxygen, as has been observed[20].

As far as can be judged from amino-acid sequences so far determined, all the residues involved in our scheme for the alkaline Bohr effect are present in all mammalian haemoglobins; they are also present in the α-chain of chicken, the only bird haemoglobin sequenced so far[21]. In the α-chains of carp the N-terminal serine is acetylated and could not contribute to the Bohr effect[22]; but histidine 122, aspartate 126 and arginine 141 are all present.

Chemical evidence bearing on our scheme will be described by Kilmartin and Wootton[13]; the temporal sequence in which the different residues liberate their hydrogen ions during the reaction with oxygen was discussed in the preceding article where it was shown that the combination of each atom of iron with ligand leads to the expulsion of the penultimate tyrosine from its pocket, and that this, in turn, breaks the salt-bridge formed by the C-terminal residue, with the liberation of a Bohr proton. This makes the liberation of Bohr protons synchronous with the uptake of haem ligands.

Model for the Binding of Organic Phosphates

2,3-Diphosphoglycerate (DPG) is present in the red cells of humans and many other species, and lowers the oxygen affinity of haemoglobin in a physiologically advantageous way[23]. It increases the free energy of haem–haem interaction but does not alter the Bohr effect. According to several investigators it binds specifically to deoxyhaemoglobin in the ratio of 1 mole/mole with a binding constant at neutral *p*H and physiological salt concentration of $1{\cdot}3 \times 10^5$, corresponding to a free energy of binding of

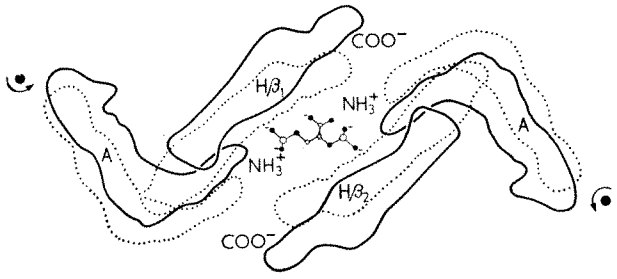

Fig. 5. Projection of the electron density maps of oxy (. . .) and deoxyhaemoglobin (———) at 5·5 Å resolution, showing the N and C-terminal portions of the β-chains grouped around the two-fold symmetry axis which is normal to the plane of the paper. In relation to Fig. 2 of the preceding article, the molecule is viewed from the top and the parts seen here are near the bottom. The DPG molecule has been tentatively placed in the central cavity, centred approximately on the two-fold axis (in fact the carboxyl group makes it unsymmetrical). The picture shows that its phosphates are close to the N-termini of the β-chains in deoxyhaemoglobin. On oxygenation the N-termini move apart and the H helices close up, thus expelling the DPG. The circular arrows indicate the positions of the axes around which the β subunits rotate on deoxygenation.

7 kcalories/mole. It also binds to free β-chains (β_4) in both oxy and deoxy states, suggesting that the binding site is on the β-chains. In certain conditions the binding is less specific and not stoichiometric, so that DPG binds to both the oxy and the deoxy forms, but the deoxy form has the higher affinity[24].

The affinity of DPG for haemoglobin is lowered by salt, showing that the binding is electrostatic, and is totally inhibited at the salt concentrations used to precipitate our crystals of deoxyhaemoglobin. For this reason we have not yet tried to determine its binding site by X-ray analysis, but fortunately Bunn and Briehl have obtained biochemical data which go far towards pinpointing that site[25]. They measured the effect of DPG on the oxygen affinities of normal human haemoglobin A and various other haemoglobins, including a minor human adult component (A_{1C}) in which the N-termini of the β-chains are covalently bound to a hexose by a Schiff base linkage; foetal human haemoglobin (F_{II}); and a minor component of human cord blood (F_I) in which the N-termini of the β-chains are acetylated. DPG increased the partial pressures of oxygen needed to produce half saturation with oxygen by a factor of 2·1 in haemoglobin A, 1·2 in haemoglobin A_{1C} and F_{II}, and unity in F_I, showing that the α-amino groups of the β-chains are involved in the binding of DPG. There is, however, clearly another nearby group which is responsible for the difference between haemoglobin A and haemoglobin F_{II}. A survey of the haemoglobin model and of the differences between the amino-acid sequences of the human β and γ-chains showed that of the residues which differ, 143(H21)β, which is histidine in adult and alanine in foetal haemoglobin, is the only likely one in the neighbourhood of the N-terminal amino groups.

When the atomic model of deoxyhaemoglobin was completed, Dr W. Bolton and I placed a model of DPG on the two-fold symmetry axis in the central cavity to see if binding to these residues would be likely on stereochemical grounds. We found that it fitted neatly so that its charged groups were within hydrogen-binding distance of the following pairs of residues of the β-chains: valine NA1(1), lysine EF6(82) and histidine H21(143). The position is shown in Fig. 5.

What happens on oxygenation ? The distance between the α-amino groups increases from 16 Å to 20 Å, so that they can no longer make contact with the phosphates of the DPG, and the helices H close up so that DPG is expelled from the central cavity. In oxyhaemoglobin this particular binding site is closed, therefore, but at this stage we cannot be sure that oxyhaemoglobin does not contain an alternative site, with a weaker binding constant, to which DPG can become attached.

Sheep haemoglobin has no affinity for DPG. The explanation is this: in its β-chain residues NA2 are deleted, which would make the non-helical segment at the amino end more than 3 Å shorter, and increase the distance between the two α-amino groups to about 22 Å, so that they could not reach the two phosphate groups of DPG.

DPG is thus seen to be stereochemically complementary to a constellation of six positively charged groups in the β-chains which face the central cavity of the haemoglobin molecule. DPG has two negatively charged groups with an average pK_a of 2·8 and three with an average pK_a of 7·1, whereas the three pairs of positively charged protein groups facing them have pK_as of 10·5, 6·8 and 7·6 respectively. Thus the charges on the DPG could be just compensated by those of the protein. This also explains why DPG does not alter the Bohr effect. On dissociation, the number of protons bound by DPG would roughly equal the number lost by the two α-amino groups and two histidines. An explanation of this general nature for the absence of a Bohr effect has been advanced[26].

ATP, ADP and AMP have binding constants with haemoglobin lower than DPG by one, two and three orders of magnitude respectively. The steric reasons for this lie in the progressive shortening of the distances between the terminal phosphate groups which weakens their interaction between the two rigidly spaced α-amino groups of the β-chains. (For fully stretched chains the distances between the terminal phosphates are 6·5 Å in 2,3-DPG, 5·5 Å in ATP and 2·8 Å in ADP.)

Pyridoxal phosphate binds to deoxyhaemoglobin in the ratio of 1 mole/mole by forming a Schiff base linkage with the α-amino group of one of the β-chains[27]. Its physiological effect is similar to that of 2,3-DPG, of which it is a competitive inhibitor. Model building shows that its phosphate group would lie near the two-fold symmetry axis of the molecule, within hydrogen bonding distance of the ε-amino groups of the two lysines EF6(82)β. The proximity of the phosphate group to the two-fold axis would inhibit the binding of a second molecule of pyridoxal phosphate. The binding site coincides with that of 2,3-DPG.

Discussion

The influence of DPG may consist simply in the stabilization of the quaternary deoxy structure where it may form the equivalent of four additional salt-bridges cross-linking the β subunits, but it probably has no direct influence on the tertiary structure of the individual subunits. Hydrogen ions, on the other hand, influence the tertiary structure of the β-chains and the quaternary structure directly by stabilizing the deoxy conformation of each. This is clearly seen by reference to Fig. 4 of the preceding article and Figs. 1 and 2. By increasing the fraction of the α-amino groups of valine 1α and imidazoles of histidine 122α that carry positive charges, H^+ directly opposes the rupture of the salt-bridges between the α-chains; the activation energy needed to expel the tyrosines from the pockets is thereby increased and, consequently, the movement of the iron atom towards the plane of the porphyrin ring which is needed for their reaction with oxygen is opposed. Similarly, in the β-chains, H^+ increases the fraction of the C-terminal histidines which carry positive charges, thereby strengthening the salt-bridges with aspartate 94 and opposing the expulsion of the tyrosines even if the quaternary structure had already clicked to the oxy conformation. The only salt-bridges not affected by H^+ near neutral *p*H are those between the C-terminal carboxyl groups of the β-chains and lysine 40α and those involving DPG.

This study has perhaps conveyed a too mechanistic picture of the cooperative effects involved in respiratory transport. In fact we should imagine a dynamic system, in which both the tertiary structure of each subunit, and the quaternary structure of the haemoglobin molecule as a whole, oscillate rapidly and continuously between the

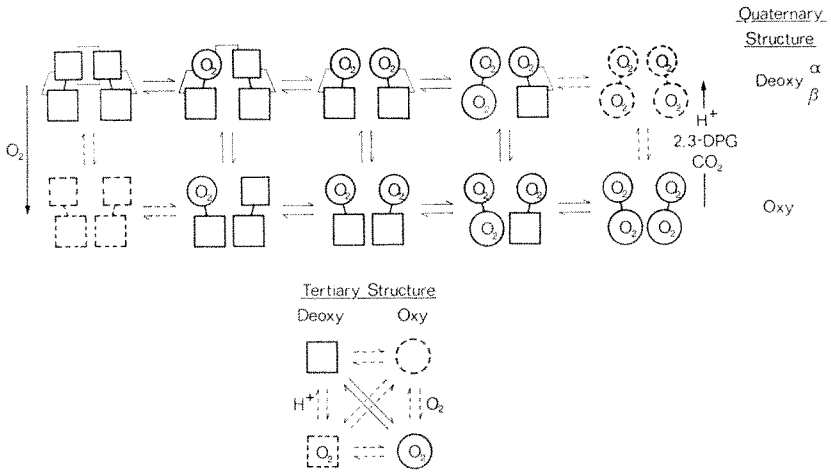

Fig. 6. Diagrammatic sketch of the allosteric mechanism of haemoglobin. The smaller subunits represent α, the larger β subunits. The clamps between them represent salt-bridges. Forms that may be too unstable to be observed have been drawn in broken lines. Note that the sequence of reaction of the individual subunits is unimportant.

oxy and the deoxy conformations. The concentrations of the different ligands alter the equilibrium between these two conformations of the various components rather than switching any of them completely to one or the other conformation (Fig. 6). This also means that the transition between the two quaternary structures could occur at any stage in the reaction, depending on the concentration of H^+, CO_2 and DPG, and on other factors, and that the mechanism would work equally well regardless of the sequence of reaction of the subunits.

I thank Dr W. Bolton for preparing the salt-free methaemoglobin crystals and Dr J. Greer for calculating the difference Fourier.

Mathematical Model of Clonal Selection and Antibody Production

by
GEORGE I. BELL
University of California,
Los Alamos Scientific Laboratory,
Los Alamos, New Mexico

Equations are developed to describe the effects of interaction between antigen and target cell. The model shows promise in predicting the constants of simple experimental systems.

When an animal is injected with a foreign substance, called an antigen, it may respond by producing antibodies, which are protein molecules that bind specifically to the antigen and hasten the elimination of the antigen from the animal[1,2]. Many features of such immune responses have been explained by the clonal selection theory[3,4] in which it is assumed that, in an adult animal, there are target cells that are capable of recognizing an antigen and being stimulated by the antigen to proliferate and produce antibodies. This clonal proliferation will lead to an increased population of target cells so that, if the animal is exposed a second time to the same antigen, the secondary response can be much more rapid and vigorous.

These notions are supported by several lines of evidence. (1) The antibody-like protein molecules which are produced by a patient with multiple myeloma are homogeneous but differ from one case to the next in their amino-acid sequences[1,2]. If it is assumed that multiple myeloma results from the uncontrolled proliferation of a single clone, starting from one target call, then all the cells in

a clone produce the same antibodies but different clones produce different antibodies. (2) The specificity of antibodies is determined by their amino-acid sequences. It is possible to denature antibodies and on renaturation their specificity and activity are recovered[5–7]. (3) The target cells seem to carry antibody-like surface receptors that combine specifically with antigen (see, for example, refs. 8, 9). Binding of antigen to surface receptors could be the mechanism whereby antigen is recognized by those cells that are able to produce the corresponding antibodies. (4) Small lymphocytes have been triggered into an active state *in vitro* by a variety of substances[10]. It is therefore tempting to believe that small lymphocytes are the target cells. Several cell types may actually be involved in triggering a primary immune response (see, for example, refs. 11–13), but the details are not yet clear.

In view of this and other evidence which supports a clonal selection theory of antibody formation, I have attempted to devise a quantitative mathematical model of clonal selection and antibody production for use in the planning and interpretation of experiments. In this article I will outline the model, report some calculations and encouraging agreement with experiment, and discuss future possibilities. (A more complete description of this work will be published elsewhere[14].) I have attempted to keep the model as simple as possible but retain enough biological content so that quantitative comparisons can be made with experiments. At present the model is restricted to the production of humoral antibodies in an adult animal. Moreover, the response to only one kind of antigen at a time is treated and the origin of the target cells and their diversity is not considered. Although it is necessary to introduce some arbitrary, but hopefully reasonable, assumptions into the model, these assumptions could, in principle, be tested by experiment and the resulting model shows agreement with experiments and suggests novel interpretations of data.

Outline of the Model

The model will be developed for a special case in which all the antibodies that are produced in response to a particular antigen are identical. A general model for heterogeneous antibody production in response to a single antigen will be sketched here for use in the comparisons with experiment.

The four kinds of cells considered in the model are indicated in Fig. 1. Target cells are initially present and capable of combining with antigen and thereby being transformed into proliferating cells which secrete antibody and rapidly divide. In the presence of sufficient antigen the proliferation continues, but when the free antigen concentration decreases to a low level, the proliferating cells divide unsymmetrically to become plasma cells, terminal antibody secreting cells, and memory cells which become, or are, functionally identical with target cells. The target, proliferating, and memory cells have antibody-like surface receptors which can combine specifically and reversibly with antigen and the number or fraction of the sites that are bound to antigen determines

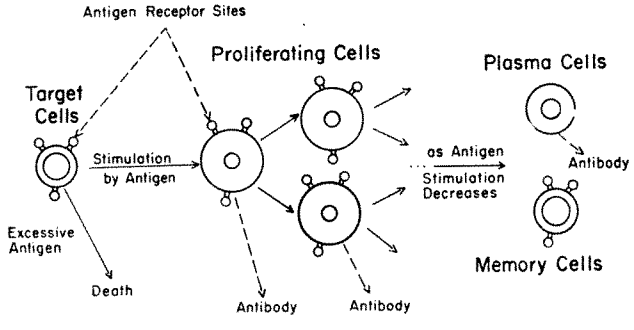

Fig. 1. Cells in the model.

the mitotic activity of a cell. Thus, if one or more sites are occupied on a target cell, it will be transformed to a proliferating cell in a mean time, T_1, though if nearly all the sites are occupied, the target cell is assumed to be killed, so that a possibility of inducing tolerance (that is, destruction of target cells) by exposure to very high antigen doses is built into the model. If many sites on a proliferating cell are occupied by antigen it will divide symmetrically in a mean time, T_2, while if less than one site is occupied, on the average, the cell will divide unsymmetrically to produce a plasma cell and a memory cell.

The binding of a cell receptor site to antigen is taken to be characterized by an intrinsic association constant, k', and the binding of antigen to antibody has the association constant, k. Conditions of chemical equilibrium can be worked out[14] for the interaction of antigen molecules having a single combining site per molecule (univalent) with antibodies having two sites per molecule (bivalent) and cells having many sites, m per molecule (multivalent). When multivalent antigens are considered, they are described by their effective number of independent antigenic sites per antigen molecule. The essential assumption of the model is that the average fraction r', and number, R' (where $R'=mr'$) of receptor sites, which are bound to antigen on a cell, determine its mitotic activity. Equations of chemical equilibrium are used to determine these quantities as functions of time.

It is assumed that the concentrations of the four kinds of cells and of antigen and antibodies are governed by ordinary differential equations in which some of the coefficients are functions of r' or R'. Let N_1, N_2, N_3 and N_4 denote the concentrations of target, proliferating, plasma and memory cells. The population of target cells will be depleted if these cells are binding antigen and we write

$$\frac{dN_1(t)}{dt} = -F(R')\frac{N_1(t)}{T_1} \qquad (1)$$

where T_1 is the mean life of a stimulated target cell (for transformation to the proliferating state or death) and thus $0 \leq F(R') \leq 1$. When $R' \ll 1$, there is only a small chance that a receptor site is occupied and stimulation is unlikely. In this case, $F(R') \ll 1$. When, on the other hand, many sites are bound to antigen, $R' \gg 1$ and it is natural to let $F(R') \simeq 1$. A simple but arbitrary choice for $F(R')$ which is used in all the following work is $F(R') = R'/(1+R')$.

Transformed target cells form the source of proliferating cells. Let this source be written $G(R')N_1/T_1$ so that G/F is the fraction of cells leaving the target state that reach the proliferating state. To allow for the induction of tolerance by high concentrations of antigen, I have assumed that G/F is small when nearly all sites are occupied; in particular, $G/F = (1-r') \equiv (1-R'/m)$.

In addition, the division of proliferating cells, with a mean life, T_2, will change the population. Let the fraction of such cells that on division remain proliferating be $(1+H(R'))/2$; the fraction that becomes plasma cells and memory cells is then $(1-H(R'))/2$. Division of a proliferating cell therefore leads, on average, to $1+H(R')$ new proliferating cells, together with $1-H(R')$ other cells. The net gain or loss of proliferating cells per division is then $H(R')$, and

$$\frac{dN_2(t)}{dt} = G(R')N_1(t)/T_1 + H(R')N_2(t)/T_2 \qquad (2)$$

According to our assumptions, when most sites are occupied (that is, when $R' \gg 1$) $H \simeq 1$ while when a site is seldom occupied (that is, when $R' \ll 1$) $H \simeq -1$. A simple choice for H with these properties is $H = (R'-1)/(R'+1)$.

Division of proliferating cells will serve as the source

of plasma and memory cells. If equal numbers of the latter are produced,

$$\frac{dN_3}{dt} = \frac{1 - H(R')}{2} N_2/T_2 - N_3/T_3 \quad (3)$$

and

$$\frac{dN_4}{dt} = \frac{1 - H(R')}{2} N_2/T_2 \quad (4)$$

where, in equation (3), T_3 is the natural lifetime of a plasma cell. (The corresponding lifetimes of target, proliferating and memory cells have been taken to be infinite in the above equations. They are assumed finite but long in the numerical work to be reported below.) According to equation (4), memory cells simply accumulate as inert cells which do not interact with antigen. To let them be equivalent to target cells, the source of memory cells $(1-H)N_2/2T_2$, is treated as a source of target cells and added to the right side of equation (1). Then N_1 will include both the target cells and the memory cells.

The differential equation for Ab(t), the concentration of antibodies, has two source terms arising from production of antibodies, by proliferating and plasma cells. If c_2 and c_3 are the rates at which a proliferating cell and a plasma cell produce antibodies, these source terms are $c_2N_2(t)$ and $c_3N_3(t)$. An antibody is assumed to have a natural lifetime T_5' while an antibody bound to antigen is taken to have a much shorter lifetime, T_5, for destruction or elimination from the system. If r is the fraction of antibody sites bound to antigen, then antibodies with two sites per molecule will be bound to antigen with the probability $2r-r^2$. Therefore,

$$\frac{d[Ab]_t}{dt} = c_2N_2(t) + c_3N_3(t) - \{(2r - r^2)/T_5 + 1/T_5'\}\,[Ab]_t \quad (5)$$

The rate of change of the antigen concentration, $d[Ag]_t$, will be the result of a possible source of antigen S_t, together with an elimination with mean life T_6 and an accelerated elimination of antigen, bound to antibodies, [bound Ag_t], with lifetime T_5, thus

$$\frac{d[Ag]_t}{dt} = S_t - \frac{[Ag]}{T_6} - [\text{bound } Ag_t]/T_5 \quad (6)$$

These six differential equations (1) to (6), together with the conditions of chemical equilibrium (which determine r, r' and R', and [bound-Ag] from N_t, [Ab] and [Ag]) and the definitions of F, G and H, constitute the equations of our model. They are to be solved subject to initial conditions on N_1, N_2, N_3, N_4, [Ab] and [Ag] for a specified antigen source S_t. Usually, a population of target cells, $N_1(0)$, is postulated, the initial concentrations of other cells and antibodies are set to zero, antigen is introduced either as an initial condition, Ag(0), or as a source, S_t, and the response of the system is determined as a function of time. Because many of the coefficients of the differential equations are functions of R' or r, which in turn depend on N_t, [Ab] and [Ag], the differential equations are non-linear and the solutions have been found by numerical methods.

So far, we have assumed that the antibodies produced in response to an antigen are all identical. In fact, even the antibodies produced in response to a simple antigen are heterogeneous, differing in association constants for binding antigen by orders of magnitude. Moreover, measurements of the association constants (affinity) and their variations with time are among the most relevant for comparison with the calculations.

In the clonal selection theory, heterogeneity of antibodies is said to arise from heterogeneity of the target cells. The model has therefore been generalized by dividing the populations of cells and antibodies into a finite number of groups. Let each group have an index $j(j = 1, 2, \ldots J)$ such that all quantities pertaining to that group have a subscript j. For example, $N_{1,j}$ is the number of target cells in group j; k_j' is their affinity for antigen, R_j' is the mean number of bound receptor sites per cell in group j, and so on. Cells (and antibodies) in the different groups have different affinities for antigen but a target cell in a particular group is assumed to produce other cells and antibodies exclusively in that group. Certain quantities are, for simplicity, assumed to be independent of j, namely, m, c_2, c_3 and all lifetimes.

With these assumptions, the foregoing equations have been generalized to allow for a multigroup representation of cell and antibody heterogeneity[14]. The resulting system of equations is solved by the program Abigail 2, on the Los Alamos digital computer, Maniac II. The program determines, at each time, the concentrations of the groups of cells, antibodies and antigen and an effective association constant, $\bar{K}$, for the population of antibodies (and free antibodies). Because of the wide range of association constants, a logarithmic scale of association constants is used in the multigroup calculation (that is, $k_{j+1} = \text{const} \times k_j$) and $\bar{K}$ is determined as $\bar{K} = \exp(\overline{\log k})$. It has been shown[14] that the resulting values of $\bar{K}$ are almost equivalent to the "average association constant, K_0" used in the immunological literature[1].

Comparison with Experiments

The model may be used to predict the response of a system, in terms of cellular proliferation and antibody production, to a prescribed exposure to antigen. In making quantitative comparisons with experiments on antibody production it is important to have experimental information on both the concentration and affinity of the antibodies or at least to know how the antibody assay depends on both these quantities. In a series of careful experiments on rabbits[15-17], antibody–antigen association constants in various conditions were measured. The antigen was bovine γ-globulin to which 2,4-dinitrophenyl (DNP) groups had been attached, and the anti-DNP antibodies were analysed. I have chosen constants in the model in an attempt to simulate this experimental system. The following values were selected[14]: $c_2 = c_3 = 7 \times 10^6$ h^{-1} (ref. 18); $T_1 = T_2 = 10$ h; $T_5 = 10$ h, $T_6 = 100$ h, $T_5' = 200$ h (ref. 1); $T_3 = 50$ h (ref. 19); $m = 10^3$. Cells and antibodies in the same group were assumed to have the same affinity for antigen, that is, $k_j = k_j'$ for $j = 1, 2, \ldots J$. The immunological system of a rabbit was taken to be a volume of 0·2 l., and an antigen molecule was assumed to have ten independent and identical DNP sites per molecule.

One thousand[18] target cells were taken, normally distributed (in log k') in seventeen groups between $k_1' = 3{\cdot}9 \times 10^3$ and $k_{17}' = 2{\cdot}6 \times 10^8$ l./mole, such that three cells were in groups 1 and 17. This choice was based on observations[15] of antibodies with association constants as high as 10^8 but with strong fluctuations between individual rabbits, suggesting few target cells of such high affinity for antigen. In many conditions, however, antibody affinities between 10^5 and 10^6 l./mole were found, suggesting a more abundant supply of corresponding target cells.

Antigen has been put into the model system, either as an initial condition or as a prolonged source. Experimentally, the antigen was injected with Freund's complete adjuvant which produces a slow absorption of the antigen by the animal[1]. Such a source was taken to be a linear function of time declining to zero at 10^3 h.

Before making detailed comparisons with the experiment, some general features of the computed response are considered. The concentration of free antigen, L, selects certain groups of cells for proliferation. A high concentration of antigen kills cells of high affinity and stimulates those of low affinity while a low concentration of antigen stimulates only cells of high affinity. Roughly, groups for which $10^{-2} \lesssim k_j'L \lesssim 1$ will proliferate most rapidly[14]. If the free antigen concentration, L, is nearly constant for a

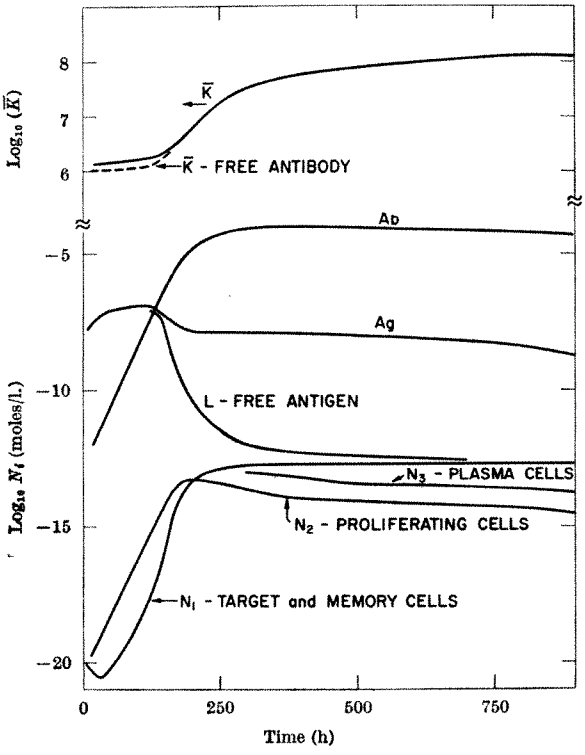

Fig. 2. Calculated concentrations and effective antibody association constant, $\bar{K}$, for a prolonged (1,000 h) source of antigen, containing 3 mg presented to the standard target cells. Parameters, given in the text, were chosen to represent DNP-bovine, γ-globulin as antigen in a rabbit.

long period of time, the antibodies will tend to have association constants reflecting this selective proliferation, that is, $10^{-2} \lesssim \bar{K}L \lesssim 1$.

The response to a typical prolonged source of antigen is shown in Fig. 2. Here, memory cells were identical to target cells so that the combined population first declines, because of the depletion of target cells, and later increases as a result of unsymmetric division of proliferating cells. At early times, the concentrations of proliferating cells and antibodies increase more or less exponentially. When the concentration of antibodies reaches the concentration of antigen, [Ab] = [Ag], the antibodies combine with much of the antigen and the concentration of free antigen begins to decrease to a low level. Cellular proliferation thereupon diminishes and the antibody population begins to decline. Note, however, that while the free antigen concentration is decreasing, the effective antibody affinity, $\bar{K}$, is increasing by about two orders of magnitude. This results from selective proliferation of those groups of cells with highest affinity for antigen.

Many features of the computed response are in agreement with experiment. The exponential increase of antibody concentration followed by a plateau and gradual decline are in general accord with experiments. The calculated increase of $\bar{K}$ from about 10^6 to 10^8 moles/l. is in excellent agreement with experiments[15], though this is partly the result of the design of the target cell affinity spectrum, $N_{1,j}(0)$. The computed variation of $\bar{K}$ is somewhat more rapid than observed.

A series of these experiments have been done with different doses of antigen, both as an initial condition (to simulate intravenous injection) and as a prolonged source (to simulate injection with adjuvant) and results are compared in Table 1. During the response to antigen as an initial condition, the antibody affinity, $\bar{K}$, does not increase much in time (compare column 3 of Table 1*A* giving $\bar{K}$ at an early time with column 5 giving the final value). The reason for this small increase is that after [Ab] = [Ag], the antigen is rapidly eliminated from the system and the free antigen concentration decreases rapidly so that there is only a short time during which the selective proliferation of high affinity cells takes place. This is in contrast to the result with a prolonged source (see Fig. 2 and Table 1*B*) where the free antigen concentration remains at a low but mildly stimulating level for a long time. Thus, if antigen is given as an initial condition it is possible to obtain high concentrations of low affinity antibodies or low concentration of high affinity antibodies. Only if the antigen is administered as a prolonged source is it possible to obtain a large amount of high affinity antibodies. This feature furnishes an explanation of the well known efficacy of adjuvants[1].

For the high doses in Table 1, cells in various high affinity groups are killed (see the last column) by the postulated mechanism of high dose tolerance. The prolonged source leads to lower antigen concentrations, destruction of fewer groups and, for this reason also, to higher affinity antibodies. It can be seen, however, that the responses to the highest doses of antigen in Table 1 predict an unreasonable amount of cellular proliferation and antibody production. I infer that when a rabbit is given such a large injection of antigen, its antibody producing system may be "overloaded" in that cellular crowding and similar effects will retard the proliferation[14].

The early values of $\bar{K}$ (third column of Table 1*B*) are in excellent agreement with the earliest values[15] measured for doses of 5–250 mg. This is shown in Fig. 3 where experimental[15] and calculated[14] values of $\bar{K}$ are compared for free antibodies. For the higher doses the measured value of $\bar{K}$ did not increase appreciably with time (in contrast to the results in Table 1*B*); this may be the result of overloading of the experimental system. Experimental[17] and calculated threshold doses to produce a barely detectable level of antibodies (50–70 μg/ml.) are in agreement at around 30 μg.

In Table 1*B*, it is seen that very small doses are leading to killing of high affinity cells. This unexpected effect is suggestive of tolerance produced by very low doses of antigen[20,21] and has been examined with care. It turns out to be the result of a detail of the numerical program[14] which does not have a clear biological counterpart. There is, however, an obvious mechanism for including low dose tolerance in the model. Consider target cells exposed to a low concentration of antigen such that $R' \ll 1$ and few target cells will be stimulated in a time T_1. The resulting proliferating cells will be weakly stimulated and will most likely divide only once. Very small clones, consisting of exactly two cells, will result. In the model it was assumed that equal numbers of memory and plasma cells arise from the proliferation, but if on average more plasma

Cell parameters simulate DNP-bovine γ-globulin as antigen in a rabbit. Column 6 represents the final concentration of memory cells plus target cells.

cells were made, then the net effect of producing these small clones would be to deplete the number of target plus memory cells. For example, if the proliferation produced three times as many plasma cells as memory cells, it would be possible to prescribe a low antigen concentration as a function of time which would reduce any initial population of target cells (plus the memory cells) to zero. This could be done without substantially affecting the response to high doses, in which very large clones are made.

Secondary responses may be simulated with the Abigail 2 program by using the memory cells from a first exposure to antigen as the target cells for the second exposure. Extensive cellular proliferation will result from the first exposure to moderate doses of antigen as shown in Table 1 and in Fig. 4. Moreover, when the first exposure is the consequence of a prolonged source of antigen, the memory cells will have high affinity for antigen and, during the secondary response, the antibodies will at all times have high affinity for antigen. The secondary response will be quicker than the primary response because of the larger number of target cells. An example is given in Table 1*C* for a 3 mg prolonged source of antigen. These qualitative features of the secondary response, quickness and high affinity antibodies, are in agreement with experiment[16,17] but comparable quantitative results do not seem to have been reported. Threshold doses in secondary responses have been compared with experiment with inconclusive results[14].

Usefulness of the Model

Considerable agreement is found between model calculations and experiments with simple antigens. How might the model be used for the planning and interpretation of experiments? First of all, the model suggests that it is useful to measure or have in mind both association constants and concentration of the quantities involved in an immune response. A concentration of free antigen will select certain cells for proliferation according to their affinity for antigen and the resulting antibodies will reflect this selective proliferation. The response will also depend on the affinity spectrum of the target cells, that is, the number of target cells as a function of affinity for antigen, and by studying the response of a system to

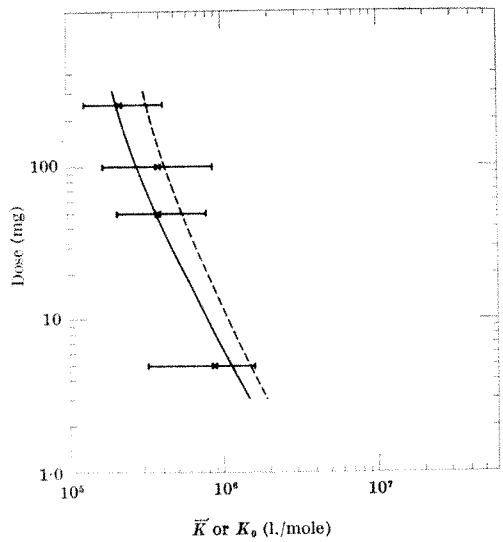

Fig. 3. Early antigen-antibody association constants. The measured value was found from a Sips plot, 2 weeks after injection of the indicated dose with Freund's complete adjuvant (ref. 15); mean and extreme values are shown with four or five rabbits for each dose. $\bar{K}$ was computed at the time when [Ag] = [Ab] and is representative of $\bar{K}$ at earlier times. —×—, Experimental values of K_0; - - -, computed $\bar{K}$ for total antibody; ———, computed $\bar{K}$ for free antibody only.

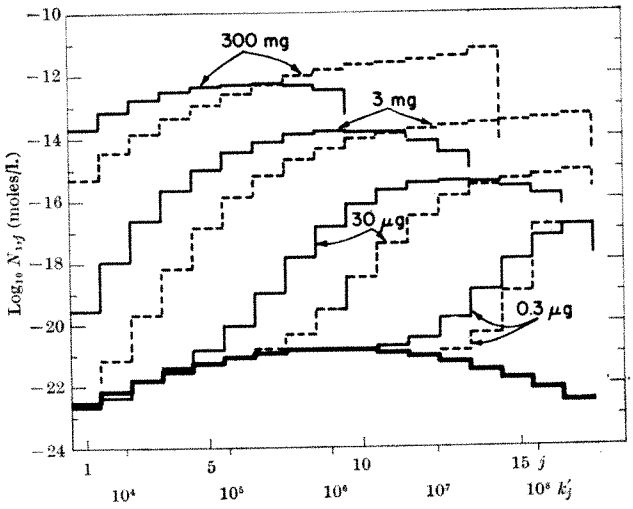

Fig. 4. Affinity spectrum for target and memory cell populations. The concentration of cells per group is shown as a function of the group index, j, and the antigen-receptor association constant or affinity, k_j'. ———, Initial target cell population: same all curves; ———, final population for rapid presentation of antigen as initial condition; - - -, final population for prolonged (1,000 h) source of antigen.

antigen it is possible to deduce some characteristics of the target cells and perhaps their origin. In particular, one can distinguish between virgin target cells and those selected by previous exposure to antigen, by both the quickness of the response and the affinity of the early antibodies[14].

If enough is known about the spectrum of target cells, then according to the model it is possible to tailor an antigen concentration to achieve special effects such as high dose tolerance, low dose tolerance or the selective proliferation of a single clone of cells, so as to produce nearly homogeneous antibody. The latter might be achieved by exposing a system having few target cells of high affinity to a prolonged low concentration of antigen. An ability selectively to produce homogeneous antibody could be of great help in elucidating the origins of antibody diversity. If, for example, two related animals were induced to produce identical antibodies, this would indicate an inheritance of the information prescribing the variable portion of the antibody.

The present model attempts to give a unified and quantitative interpretation of diverse immunological data; it suggests connexions and interpretations which might otherwise remain obscure. For example, we have already noted that certain high doses of antigen ($\gtrsim$30 mg of DNP bovine γ-globulin in rabbits) may lead to overloading of the immunological system in the sense that crowding of cells and similar effects change the response. A mechanism of low dose tolerance has also been suggested, namely, production of very small clones in which less than half the cells are memory cells. As a final example, I offer the speculation that heavy (19S) antibodies are produced by proliferating cells while light (7S) antibodies are produced by plasma cells. In the calculations, most antibodies early in the primary response come from proliferating cells; later in the primary response and at nearly all times in the secondary response the antibodies are largely of plasma cell origin. These time behaviours are analogous to those observed for the 19S and 7S antibodies[1]. In addition, it has been reported[22] that heavy and light antibodies have common genetic determinants in their variable portions, suggesting a clonal relationship of the producing cells.

Clearly many of the assumptions of the model are quite arbitrary, for example, the number of sites per cell, and the functions F, G and H which determine the response of the cells to antigen. Quantitative experiments on the

interactions between cells and antigen would therefore be valuable for confirming or denying the basic assumptions of the model. Progress has already been made in separating cells that bind particular antigens[23,24] and it is hoped that these antigen-cell interactions may be quantitatively characterized in the near future.

I thank Drs Herman Eisen, David Talmage, and Henry Clamen for helpful discussions and Mrs Dorothy Williamson for assistance in preparing and operating the computer program. This work was done under the auspices of the US Atomic Energy Commission.

Reconstitution of 50S Ribosomal Subunits from Dissociated Molecular Components

by
M. NOMURA
V. A. ERDMANN

Laboratory of Genetics and Institute for Enzyme Research,
University of Wisconsin,
Madison, Wisconsin

50S ribosomal subunits of *Bacillus stearothermophilus* have been reconstituted by incubating their RNA and protein components at high temperatures.

30S RIBOSOMAL subunits have been reconstructed *in vitro* from their molecular components for ribosomes from several different species of bacteria[1,2]. This has made it possible to determine the parts that individual molecular components play in the function of the ribosomes[2-4] and to describe in some detail the events leading to the assembly of the 30S subunit from its parts[5,6,10].

The 50S subunit of the ribosome has been less tractable. It is much more complex than the 30S subunit, and contains two RNA molecules—with sedimentation coefficients of 23S and 5S—and about 35 distinct protein components (ref. 25 and C. G. Kurland, personal communication). This structural complexity could account for the difficulty of reconstituting 50S subunits *in vitro*; only partial reconstructions from protein deficient "core" particles and split proteins have been achieved[7-9]. None of these experiments revealed a functional requirement for 5S RNA. We now report that using *Bacillus stearothermophilus* 50S subunits, we can reconstitute "50S" particles with considerable protein-synthesizing activity from dissociated RNA and protein components. Using this system, there is a partial requirement for 5S RNA in the reconstitution of functional 50S particles.

Reconstitution of 50S Subunits

One striking characteristic of the 30S reconstitution reaction is its strong temperature dependence. An Arrhenius activation energy of about 40 kcalories/mole has been obtained by measuring the rate of reconstitution of *Escherichia coli* 30S subunits at various temperatures[10]. 50S reconstitution might have a much higher free energy of activation and therefore require a higher incubation temperature to achieve a measurable rate of assembly *in vitro*. This would explain the lack of success in attempts to reconstitute *E. coli* 50S subunits. To permit higher incubation temperatures without inactivating the ribosomes, we decided to use a thermophilic bacterium, *B. stearothermophilus*. Reconstitution of 30S subunits from this organism has previously been studied[2].

RNA ("RNA50") and protein ("TP50") fractions were prepared by treating purified 50S ribosomal subunits with urea-LiCl as described in the legend to Fig. 1. Usually, more than 90 per cent of RNA was recovered in the RNA fraction and only a few per cent of RNA was found in the protein fraction. The amount of residual protein in the RNA50 fraction was about 2 to 3 per cent of that in an equivalent amount of 50S subunit. The residual proteins in "RNA50" fractions were analysed by standard polyacrylamide gel electrophoresis at *p*H 4·5 (ref. 11) after digestion of RNA with ribonuclease. Two weak bands were observed, both of which had counterparts with much higher intensities in the control gel made with an equivalent amount of TP50 fraction. Thus extraction of these two proteins by the urea-LiCl method was not complete, and the RNA fraction used for the reconstitution probably consists of a mixture of free RNA molecules and RNA molecules associated with these two proteins. Whether the reconstitution of functional 50S particles to be described below is really from free RNA or from RNA molecules with these proteins still tightly bound is not established. Fig. 1*a* shows the sedimentation pattern of the "RNA50" preparation analysed on a sucrose gradient. Intact 23S rRNA was a single peak. About 70 per cent of the 5S RNA was present in the protein fraction (TP50) and about 30 per cent in the "RNA50" fraction.

In many earlier experiments, the protein preparation was simply diluted with the reconstitution buffer and then mixed with the RNA preparation and heated at 60° C for 45 min as described in the legend to Fig. 1. The standard conditions for reconstitution were determined from several experiments to be described below. After incubation, particles were recovered and analysed by sucrose density gradient centrifugation in the presence of a small amount of reference ^{32}P-50S subunits. Fig. 1*b* shows that most of the original 23S ribosomal RNA (rRNA) then sedimented in a single peak which coincided with the peak of the reference ^{32}P-50S subunits. Thus the

addition of the 50S protein fraction to the RNA preparation converted most of the 23S rRNA to particles sedimenting at 50S.

Biological activity of the reconstituted particles was determined by using a poly U-directed polyphenylalanine synthesizing system[12] in the presence of 30S ribosomal subunits, and comparing this with the activity of control (undissociated) 50S subunits which were treated in the same way. The activity of the control 50S ribosomal subunits varied with the preparation, but remained about the same in different experiments as long as the same preparation was used. Table 1 and Fig. 2 show that reconstituted particles have definite incorporation activity. Neither the protein fraction alone nor the RNA fraction alone showed any significant activity (Table 1, experiments 1, 2 and 3). The degree of restoration of synthetic activity varied from 15 per cent to about 60 per cent depending on the experiment. One possible source of variation might be variable inactivation of the components during the incubation (60° C, 45 min). The presence of small amounts of urea in the reconstitution mixture in earlier experiments (final concentration 0·02 to 0·2 M) may be responsible for this inactivation. The reconstitution activity was higher when dialysed TP50 fraction was used. In addition, kinetic experiments with dialysed TP50 fraction suggested less inactivation during the incubation at 60° C over extended periods. For the sake of convenience, however, many earlier experiments to optimize conditions for reconstitution were done using undialysed protein preparations. The degree of reconstitution after 30 min incubation at 60° C was essentially constant at different urea concentrations used in these experiments (between 0·02 and 0·2 M urea). At 0·4 M or higher urea concentration, reconstitution was definitely impaired.

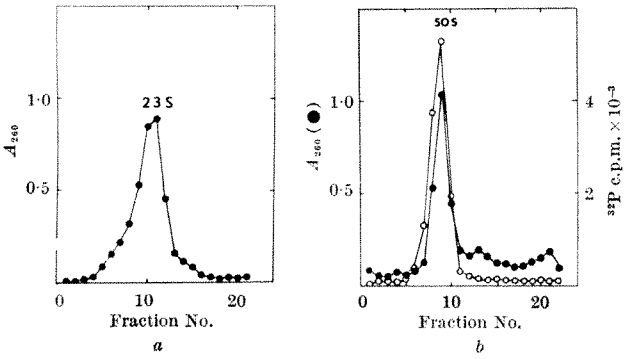

Fig. 1. Sucrose gradient sedimentation pattern of "RNA50" used for the reconstitution (*a*) and particles recovered from the reconstitution mixture (*b*). RNA and proteins used for the reconstitution were prepared as follows: purified 50S ribosomal subunits in TMAI buffer (about 200 to 500 A_{260} units per ml.) were mixed with an equal volume of 8 M urea-4 M LiCl solution and kept in an ice bath for 40 to 50 h. (In other experiments, ribosomes were treated with an equal volume of 8 M urea-4 M LiCl solution plus 0·6 volume of 10 M LiCl solution.) The mixture was centrifuged (10,000 r.p.m. for 20 min), and the supernatant was used as total 50S ribosomal proteins (TP50). Precipitated RNA was washed with a mixture of 8 M urea-4 M LiCl solution and TMAI (1 : 1), and then dissolved in H_2O. Composition of TMAI is as follows: 10^{-2} M Tris-HCl (*p*H 7·8)–10^{-2} M $MgCl_2$–3×10^{-2} M NH_4Cl–6×10^{-3} M mercaptoethanol. Reconstitution was done as follows: 10 A_{260} equivalents of 50S proteins (in about 50 μl.) prepared as above were diluted with 5 ml. of the standard reconstitution buffer: 10^{-2} M Tris-HCl (*p*H 7·5)–2×10^{-2} M $MgCl_2$–0·3 M KCl–6×10^{-3} M mercaptoethanol. 1 A_{260} equivalent is defined as the amount of protein which can be obtained from 1 A_{260} unit of ribosomes. RNA prepared as above (10 A_{260} units in 30 to 100 μl.) was added. The mixture was heated at 60° C for 45 min, and then cooled in ice. 0·65 volume of ethanol (precooled at −20° C) was added and the mixture was kept for about 1 h at −20° C. The reconstituted ribosomal particles precipitated in this way were recovered by centrifugation and dissolved in 0·2 ml. of TMAI. Aliquots were used for analyses of incorporation activity and/or sedimentation pattern of the reconstituted particles. In *a*, about 5 A_{260} units of RNA preparation were mixed with a small amount of reference ^{32}P-labelled 50S ribosomal subunits and put on a sucrose gradient (5–20 per cent in TMAI buffer, 4·6 ml.) and centrifuged at 45,000 r.p.m. for 100 min in the cold. Fractions were collected from the bottom of the tube, suitably diluted and both A_{260} and radioactivity were measured. The peak of ^{32}P-50S was at fraction 6. In *b* the reconstituted "50S" particles (about 10 A_{260} units) were mixed with a small amount of ^{32}P-labelled 50S ribosomal subunits (less than 0·5 A_{260} unit), put on a sucrose gradient (10–30 per cent in TMAI buffer, 16 ml.) and centrifuged at 22,500 r.p.m. for 18 h in the cold. Fractions were collected and measured for both A_{260} and ^{32}P.

Table 1. POLYPEPTIDE SYNTHETIC ACTIVITY OF 50S PARTICLES RECONSTITUTED FROM DISSOCIATED RNA AND PROTEIN COMPONENTS

TP50: Total proteins prepared from 50S by urea-LiCl method; "RNA50": RNA fraction prepared from 50S by urea-LiCl method; "RNA30": RNA fraction prepared from 30S by urea-LiCl method; "RNA50(phenol)": total RNA (23S and 5S) prepared from 50S by phenol extraction method.

Reconstitution procedures are described in the legend to Fig. 1. Reconstituted "50S" particles were recovered by alcohol precipitation. Aliquots containing 1·4 A_{260} units of particles were assayed for poly U-directed phenylalanine incorporation activity in the presence of 1·0 A_{260} unit of *E. coli* 30S ribosomal subunits according to the method described previously[23]. Undissociated *B. stearothermophilus* 50S ribosomal subunits treated in the same way were used as control. The treatment (that is, heating in the reconstitution mixture at 60° C for 45 min and alcohol precipitation after cooling) resulted in reduction of activity of control 50S ribosomal subunits to 40 per cent of the original activity. This reduction took place almost entirely during the alcohol precipitation step; and the heating step itself did not cause any significant reduction. Because the degree of activity reduction was the same in each set of experiments, the alcohol precipitation could be used without introducing uncontrollable variations. In experiment 2, "23S RNA" was prepared as follows: "RNA50" prepared by the urea-LiCl method was centrifuged on a sucrose density gradient. The A_{260} of aliquots was measured, peak fractions containing 23S RNA (see Fig. 1*a*) were pooled, and RNA was recovered by alcohol precipitation. In experiment 4, "RNA50(phenol)" was prepared as follows: 50S ribosomal subunits (in TMAI) were treated with phenol (saturated with 0·15 M NaCl–0·015 M sodium citrate) in the presence of 0·17 per cent bentonite. Phenol extraction was repeated six times. RNA was finally precipitated with 2 volumes of alcohol, dissolved in H_2O and dialysed overnight against H_2O. The reconstitution was done as described before except that 5 A_{260} units of purified *B. stearothermophilus* 30S ribosomal subunits were added in the 5 ml. reconstitution mixture as indicated. After incubation at 60° C for 45 min, the reaction mixtures were cooled in ice. Five A_{260} units of 30S subunits were added to the tubes which did not have 30S subunits. The reconstituted particles as well as added 30S subunits were then recovered by the alcohol precipitation method.

Table 1 also compares the activities obtained with several different RNA preparations. First, RNA ("RNA50") prepared by the urea-LiCl method can be purified by sucrose gradient centrifugation followed by alcohol precipitation. The 23S rRNA obtained from the peak region after sucrose gradient centrifugation was as active as the starting RNA preparation (Table 1, experiment 2). This result is not surprising, for we have found that the protein fraction contains most of the 5S RNA.

In contrast to "RNA50" prepared by the urea-LiCl method, RNA prepared by phenol treatment of 50S subunits was only weakly active (Table 1, experiment 4, and Fig. 2). The difference between "RNA50" and "RNA50 (phenol)" does not seem to result from incomplete removal of proteins from "RNA50". Several RNA preparations made by repeated phenol extractions were analysed for residual proteins by the ribonuclease digestion-polyacrylamide gel electrophoresis technique. This "RNA50 (phenol)" also contained the same two protein bands in amounts comparable with those in the "RNA50" preparation. The difference in activity between two kinds of preparation may be due to difference in their conformation. "RNA50" was prepared in the presence of 5×10^{-3} M Mg^{2+}, whereas "RNA50(phenol)" was prepared by repeated extraction of 50S with phenol saturated with a solution of NaCl (0·15 M) and sodium citrate (0·015 M). The former showed a slightly higher sedimentation coefficient (2–3S) than the latter in several conditions. In polyacrylamide gel electrophoresis, the former moved slightly faster than the latter. These results suggest that "RNA50" has a more compact structure than RNA prepared by the phenol method.

Table 1 (experiment 3) also shows that RNA (16S rRNA, called "RNA30" here) prepared from 30S subunits by the same urea-LiCl method cannot replace RNA

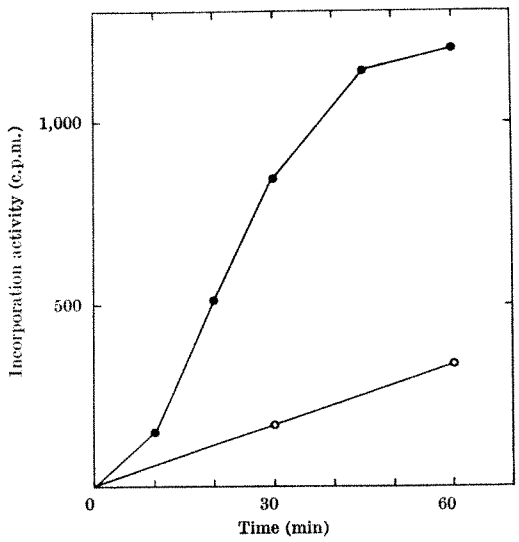

Fig. 2. Time course of reconstitution. Reconstitution procedures were as described in the legend to Fig. 1. After various times of incubation at 60° C, the reconstitution reaction was stopped by cooling, and particles were recovered by alcohol precipitation. Aliquots containing 1·5 A_{260} units of RNA were analysed for the incorporation activity. Closed circles: with "RNA 50"; open circles: with RNA prepared by phenol extraction method.

(23S rRNA) from 50S subunits. The same "RNA30" was fully active in 30S reconstitution (see Fig. 4). The 30S subunit preparation which was used to prepare RNA ("RNA30") for the experiment in Table 1 contained a small amount of 50S subunits (about 10 per cent of the total amount). This contamination can account for the weak activity of "RNA30" when tested with TP50. This shows that the requirement for RNA is specific.

Efficiency of Reconstitution

We have examined the effect of several factors on the efficiency of reconstitution by measuring the degree of reconstitution at times when reconstitution was still proceeding (usually after 30 min incubation, see Fig. 2). Thus the degree of reconstitution measured roughly reflects the rate of reconstitution, although precise information on kinetics of the reconstitution cannot be obtained from these results.

Fig. 3 shows the effect of KCl concentration on reconstitution. As in the case of reconstitution of *E. coli* 30S subunits (optimum ionic strength about 0·37, ref. 10), there is a sharp ionic strength optimum (about 0·33) for the reconstitution of 50S particles. If the ionic strength of the reconstitution mixture is below 0·1 or above 0·8, very little reconstitution takes place. The optimum ionic strength is about the same in these two different reconstitution systems, namely, *E. coli* 30S and *B. stearothermophilus* 50S reconstitutions.

The high ionic strength is probably needed to prevent non-specific RNA–protein or protein–protein interactions, as it is with *E. coli* 30S reconstitution[5,10]. The inhibition by higher ionic strength may be caused either by a weakening of specific interactions by high salts or by the formation of an inactive, highly compact ribosomal RNA structure.

Fig. 4 shows the effect of the temperature of incubation. The degree of reconstitution after incubation for 30 min was compared at different temperatures. For comparison, the effect of temperature on the reconstitution of 30S subunits from the same organism was examined in identical reconstitution conditions. The degree of reconstitution of 30S subunits after 5 min incubation at various temperatures is shown in Fig. 4. There is a marked difference in temperature dependence between 30S and 50S ribosome reconstitution. At 50° C, 30S reconstitution is more than 50 per cent complete in 5 min, whereas 50S reconstitution is barely detectable even after 30 min incubation.

The optimum temperature for 50S ribosome reconstitution is about 60° C. At 65° C, the efficiency of reconstitution drops, presumably because of heat inactivation of ribosomal components, intermediates or finished reconstituted "50S" particles. Thus 60° C was selected as the standard incubation temperature.

Cells of *B. stearothermophilus* multiply with a doubling time of about 15 min at 60° C. Thus although 50S ribosomal subunits can be assembled *in vitro*, their rate of assembly is much slower than the rate of assembly *in vivo* or that of 30S subunits under identical *in vitro* conditions.

Effect of 30S Subunits on Reconstitution

Genetic studies in our laboratory strongly suggest that the assembly of 50S ribosomal subunits *in vivo* is aided by participation of 30S ribosomal subunits or their precursor particles (ref. 13, and unpublished results of Nashimoto and Nomura). We therefore added purified 30S ribosomal subunits in an amount equivalent to that of the "RNA50" present in the system, incubated the mixtures for various times at 60° C, and compared the incorporation activity of the resultant particles with that of the control particles reconstituted in the absence of 30S subunits. 30S subunits were added to the control sample after the incubation. They frequently gave a significant stimulation of reconstitution, but the effect was not reproducible. A more reproducible stimulatory effect was observed when RNA50 prepared by the phenol extraction method was used instead of "RNA50" prepared by the urea-LiCl method. An example is shown in Table 1 (experiment 4). Even with phenol-prepared RNA, however, the stimulatory effect of 30S subunits was not always observed. The reason for this variability as well as the significance of the apparently positive stimulatory effect of 30S in many experiments is not clear. Thus we still do not know whether the coupling of 50S subunit biosynthesis with 30S biosynthesis inferred from *in vivo* work can be demonstrated *in vitro*.

5S RNA and 50S Reconstitution

The 50S ribosomal subunit contains one molecule of 5S RNA[14]. The role of 5S RNA is unknown. We have

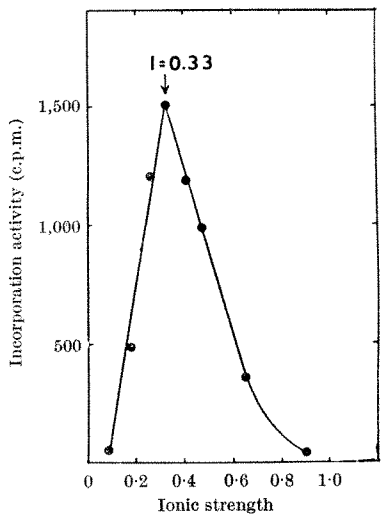

Fig. 3. Effect of ionic strength on reconstitution. 10 A_{260} units of "RNA50" were mixed with the equivalent amount of 50S proteins in 5 ml. of reconstitution buffer which had the standard concentration of all components (see the legend to Fig. 1) except KCl. KCl concentration was varied and the final ionic strength of the reconstitution buffers is shown on the abscissa. The mixtures were incubated at 60° C for 30 min and the reconstituted particles were recovered by alcohol precipitation as described in the legend to Fig. 1. Aliquots of the particle containing 1·5 A_{260} units were assayed for their activity in poly U-directed ^{14}C-phenylalanine incorporation.

done preliminary fractionation of the present reconstitution system in order to see whether 5S RNA is required for 50S function.

Analysis of ^{32}P-labelled 50S subunits showed that the principal portion (about 70 per cent) of 5S RNA is present in the protein fraction obtained by the urea-LiCl method. The protein fraction was dialysed against urea-Tris buffer containing 0·2 M KCl and then fractionated by DEAE-cellulose column chromatography as described in Table 2. Most of 5S RNA was eluted by 1 M KCl (fraction C), but not by 0·3 M KCl. Reconstitution experiments were then performed using separated fractions (Table 2). In the absence of fraction C, only weak 50S activity was observed after reconstitution. Addition of fraction C to the system increased the degree of reconstitution by a factor of about two. Analysis of RNA in fraction C by polyacrylamide gel electrophoresis[24] showed that it contains 5S RNA in addition to a very small amount of high molecular weight RNA and 4S RNA. Both *E. coli* 5S RNA and *B. stearothermophilus* 5S RNA purified by a standard gel filtration method[15] could replace fraction C in the stimulation of reconstitution (Table 2). This shows that 5S RNA is an important component of the 50S subunit. 5S RNA is also present in the "RNA50" fraction used in the reconstitution, and this may explain why we could not get a higher stimulatory effect of 5S RNA.

Using protein-deficient particles, Monier and his co-workers demonstrated specific reassociation of 5S RNA with ribosomal particles[16–18]. But their reconstituted "48S particle" did not have incorporation activity. In the present reconstitution system, we also studied incorporation of 5S RNA into reconstituted particles. Radioactive 5S RNA was prepared from ^{32}P-labelled 50S subunits in the following way: the protein fraction obtained by the urea-LiCl method was fractionated by DEAE-cellulose column chromatography as described in Table 2, and fraction C was extracted with phenol. RNA recovered by alcohol precipitation was further purified by sucrose gradient centrifugation to remove a small amount of high molecular weight RNA. This ^{32}P-5S RNA preparation was about 95 per cent pure as judged by polyacrylamide gel electrophoresis. Contamination by ^{32}P-transfer RNA was very small. This ^{32}P-5S RNA was added to the usual reconstitution mixture containing non-radioactive 5S RNA. The amount of ^{32}P-5S RNA added was about equal to that already present in the reconstitution mixture. After incubation, reconstituted particles as well as any residual RNA were recovered by alcohol precipitation and analysed by zonal sedimentation on a sucrose gradient in the presence of reference ^{3}H-50S subunits. As shown in Fig. 5, about 55 per cent of ^{32}P-5S RNA co-sedimented with the reconstituted particles in a single peak which coincided with the peak of reference ^{3}H-50S subunits. We conclude that externally added ^{32}P-5S RNA was incorporated into 50S particles. This incorporation seems to be quantitative—that is, every reconstituted "50S" particle has about one 5S RNA molecule in addition to one 23S rRNA molecule.

Table 2. FRACTIONATION OF 50S RIBOSOMAL PROTEINS AND STIMULATORY ACTIVITY OF 5S RNA

Exp.	Fractions added together with "RNA50"	50S activity c.p.m.	50S activity Per cent	Stimulation by "5S"
1	A	83	5	—
	A+B	279	16	(1·0)
	A+B+C	447	26	×1·6
	A+B+*E. coli* 5S	623	36	×2·2
	(Control 50S)	(1,746)	(100)	
2	A+B	229		(1·0)
	A+B+C	542		×2·4
	A+B+*B. stear.* 5S	461		×2·0

A, 0·2 M KCl eluate fraction obtained from TP50 in DEAE-cellulose column chromatography, 10 A_{260} equivalents per tube; B, 0·3 M KCl eluate fraction, 10 A_{260} equivalents per tube; C, 1 M KCl eluate fraction containing 5S RNA, 0·35 A_{260} units per tube; *E. coli* 5S, pure *E. coli* 5S RNA, 2·0 A_{260} units per tube; *B.s tear.* 5S, pure *B. stearothermophilus* 5S RNA, 1·8 A_{260} units per tube.

About 140 A_{260} equivalents of TP50 fraction prepared as described in the legend to Fig. 1 were dialysed overnight against the buffer containing 4 M urea–0·01 M Tris, *p*H 7·8–0·2 M KCl–10^{-3} M $MgCl_2$, and then applied to a small DEAE-cellulose column (1·0 cm × 1·3 cm). The column was washed with the same buffer, and materials which came through were called fraction A. The column was then eluted with the same buffer but containing 0·3 M KCl (fraction B), and finally with the buffer containing 1 M KCl (fraction C). Fraction C was dialysed overnight against H_2O. The reconstitution mixture contained, in a final volume of 5·7 ml. 10 A_{260} units of "RNA50", and in addition, fractions A, B, C and pure *E. coli* 5S RNA or *B. stearothermophilus* 5S RNA as indicated. Final ionic strength was adjusted to 0·33 and final urea concentration to 0·2 M. After incubation at 60° C for 45 min, the reconstituted particles were recovered by alcohol precipitation and aliquots containing about 1·4 A_{260} units of RNA were assayed for poly U-directed phenylalanine incorporation activity.

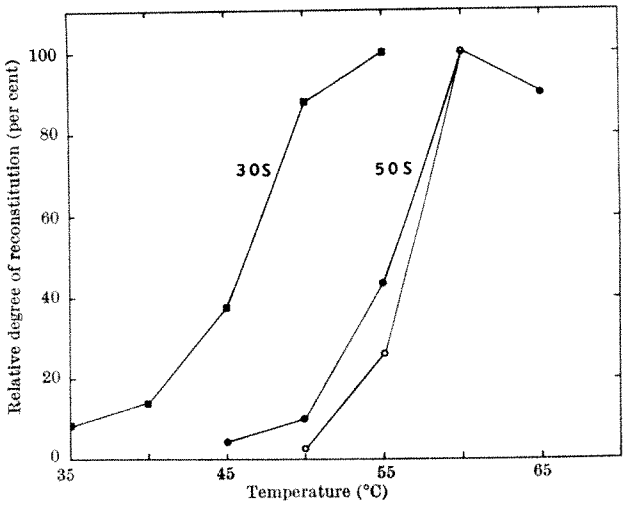

Fig. 4. Effect of temperature on reconstitution. Reconstitution of 50S subunits was done in two ways at different temperatures. The incubation time was 30 min in both cases. In one case (○) reconstitution was done as described in Fig. 1. In the other case (●), reconstitution was done using dialysed TP50 preparation as follows. The reconstitution mixture contained 4·8 A_{260} units of "RNA50" and 8·0 A_{260} equivalents of dialysed TP50 in the final volume of 0·48 ml. Other components in the reaction mixture were the same as in the first method. After incubation for 30 min at 60° C, aliquots containing 1 A_{260} unit of particles (100 μl.) were taken and the polypeptide synthesizing activity of reconstituted particles was assayed directly (without alcohol precipitation) at 37° C using the poly U-directed phenylalanine incorporation system. In both cases, the activity obtained at 60° C (1,330 c.p.m. and 463 c.p.m., respectively) was taken as 100 per cent. Reconstitution of 30S subunits was done using the same conditions as used for 50S reconstitution in the second case above (■). Both RNA and proteins were prepared from the purified 30S subunits. Reconstitution mixtures were incubated at the indicated temperatures for 5 min. The incorporation activity (assayed by poly U-directed phenylalanine incorporation in the presence of 50S subunits) obtained at 55° C was taken as 100 per cent which corresponded to 53 per cent of the activity of the control 30S subunits treated in the same way.

Significance of *in vitro* 50S Reconstitution

Although 50S subunits are probably reconstituted from completely protein-free RNAs, the RNA fraction used for the reconstitution contained a small amount of two different proteins. It is therefore possible that the presence of these proteins bound to 23S rRNA is important for reconstituting functional 50S particles. Physical conversion of 23S rRNA to particles sedimenting at 50S is almost quantitative. In this case, protein-free 23S rRNA is certainly converted to "50S" particles, which may or may not be functional. Incorporation of protein-free 5S RNA molecules into "50S" particles is also quantitative. The present reconstitution system will be useful in the study of the physical and functional roles of the molecular components of 50S subunits, as exemplified by our preliminary experiments on the role of 5S RNA.

50S subunits can be reconstituted in the absence of any other external macromolecular components, which demonstrates that the information for their assembly is contained in the structure of their molecular components, as is the case with 30S subunits. The *in vitro* assembly reaction in the present system, however, is too slow to account for the efficient ribosome assembly reaction which takes place *in vivo*. Perhaps our *in vitro* conditions are not fully optimized. Alternatively, the *in vivo* assembly reaction may be much faster because it uses immature submethylated precursor 23S RNA[20–22] (and precursor

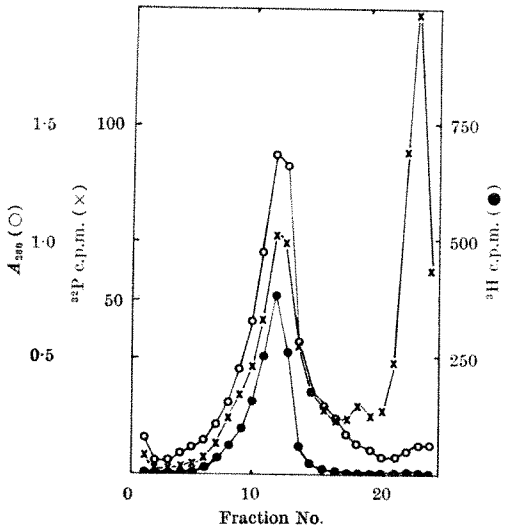

Fig. 5. Incorporation of ^{32}P-5S RNA into the reconstituted "50S" particles. The reconstitution of "50S" particles was done in the same way as described in the legend to Fig. 1 except that about 0·4 A_{260} units of ^{32}P-labelled 5S (about 800 c.p.m.) were added to the reaction mixture before the incubation. After the incubation at 60° C for 45 min, the reaction mixture was cooled to 0° C. The reconstituted particles were recovered by alcohol precipitation, mixed with a small amount of reference ^{3}H-labelled 50S (about 0·05 A_{260} unit), and then subjected to a sucrose gradient sedimentation analysis (5–20 per cent sucrose in TMAI buffer, 100 min at 45,000 r.p.m.). Fractions were analysed for A_{260}, ^{3}H and ^{32}P.

5S RNA[19]) instead of mature 23S rRNA (and 5S RNA). But we should emphasize that reconstitution of 30S subunits from the same organism is much faster under identical *in vitro* conditions (see Fig. 4) and that this reconstitution is performed using mature 16S rRNA rather than immature precursor RNA. Assuming first order reaction kinetics for both 30S and 50S assembly (see ref. 10), we have calculated the approximate rate constants at 50° C for both 30S and 50S assembly reactions, using experimental data similar to those described in Fig. 4. The calculation showed that the rate of assembly of 30S is about 300 times faster than that of 50S at 50° C. In contrast to this *in vitro* situation, 30S and 50S ribosomal subunits are synthesized coordinately *in vivo*, with about equal numbers of both particles synthesized per unit time per cell in growing bacterial cells under normal conditions. Such considerations suggest that the assembly of 50S subunits is facilitated *in vivo* by some special mechanism which is not involved in the 30S assembly *in vivo*. As will be reported elsewhere, genetic studies in our laboratory have shown that all mutational alterations discovered so far which inhibit 30S ribosome assembly also inhibit 50S assembly, whereas many mutations which abolish 50S assembly do not appear to affect 30S assembly[13,26]. Thus we propose that assembly of 50S subunits somehow depends on simultaneous assembly of 30S subunits *in vivo*, while the assembly of 30S subunits is independent of 50S assembly[26]. The present *in vitro* 50S reconstitution system may offer an experimental system for the investigation of the mechanism for this apparent coupling of 50S assembly with 30S assembly *in vivo*.

We thank Dr C. Nepokroeff, Mr K. Higo, Mrs K. Foss and D. Becker for technical assistance; Dr M. Susman and Mr C. V. Lowry for reading the manuscript; and Dr J. C. Garver for the use of his pilot plant. This work was supported by grants from the US National Institutes of Health, Institute of General Medical Sciences and the National Science Foundation. Operation of the Biochemistry Department's pilot plant is supported by a grant from the National Institutes of Health.

Factor Necessary for Ribosomal RNA Synthesis

by

ANDREW A. TRAVERS*
ROBERT I. KAMEN†
ROBERT F. SCHLEIF‡

The Biological Laboratories,
Harvard University,
Cambridge, Massachusetts

A transcription factor, Ψ_r, which preferentially stimulates the synthesis of ribosomal RNA *in vitro* has been identified in crude extracts of *E. coli*. This factor activity is also a component of Qβ replicase.

Ribosomal RNA cistrons comprise only 0·2 to 0·4 per cent of the genome of *Escherichia coli*[1,2] and yet, in a rapidly growing culture, rRNA synthesis can account for up to 40 per cent[2,3] of the instantaneous rate of total RNA synthesis. This high rate of synthesis per cistron is much greater than that of most mRNA species and suggests that there may be some fundamental difference in the transcription processes. Because streptovaricin[4] and rifampicin (unpublished observations of R. F. S.) inhibit rRNA synthesis, and their target is the core RNA

polymerase[5,6], at least one subunit of the polymerase must be used in the synthesis of rRNA; probably the entire core is used. But when highly purified RNA polymerase with or without the sigma factor is used to transcribe highly purified *E. coli* DNA, no detectable rRNA is synthesized. In such an experiment (Fig. 1) labelled rRNA is hybridized to *E. coli* DNA in the presence of increasing amounts of unlabelled *in vitro* product of the RNA polymerase reaction. This assay can detect rRNA levels in excess of 0·2 per cent of the *in vitro* product. Because, as shown in Fig. 1, this level is not attained, the proportion of rRNA made *in vitro* must be less than the proportion of rDNA in the template. The failure to synthesize appropriate quantities of rRNA suggests that the purified *in vitro* system lacks some effector necessary for the preferential synthesis of rRNA. We report here the identification of such an effector, which stimulates the *in vitro* synthesis of rRNA by RNA polymerase containing sigma. This activity, termed Ψ_r, has been found both in crude extracts of *E. coli* and as a component of phage Qβ RNA replicase.

The effector responsible for the preferential synthesis of rRNA could act in either of two ways. A change in the initiation specificity of RNA polymerase could be mediated by a factor which acted directly on core polymerase. For example, such a factor appears during T4 phage development[7,8]. Alternatively the factor could interact with complete enzyme (core polymerase plus sigma) as suggested for the CAP factor[9,10], which is necessary for the transcription of operons under catabolite repression control.

To search for additional *E. coli* transcription factors, we first fractionated a ribosome-free crude extract by zone sedimentation in a glycerol gradient at high ionic strength ($I = 0{\cdot}5$). The resulting fractions were then assayed for their ability to stimulate transcription of *E. coli* DNA by either core RNA polymerase or RNA polymerase holoenzyme. Assaying with holoenzyme

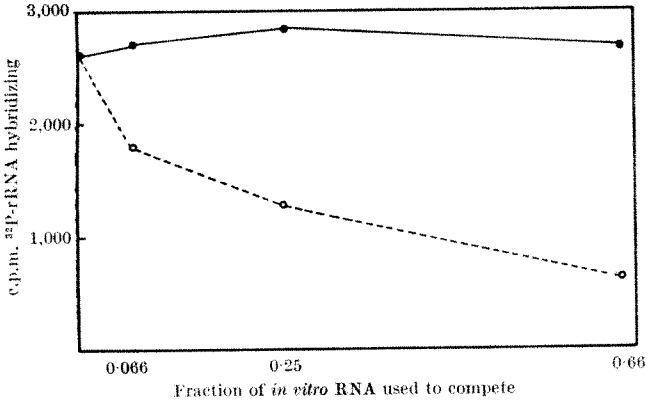

Fig. 1. Competition of radioactive rRNA by non-radioactive *in vitro* RNA. Two 1 ml. reactions containing 25 μg *E. coli* DNA, 10 μg complete enzyme, 0·01 M KCl, 0·04 M Tris-HCl (*p*H 7·9), 0·01 $MgCl_2$, 10^{-4} M EDTA, 10^{-3} M KH_2PO_4, 6×10^{-3} M 2-mercaptoethanol and 0·15 mM triphosphates. One reaction contained in addition 0·2 μg rRNA. A parallel reaction with ^{14}C-UTP showed that 30 μg total of RNA was synthesized per reaction. After incubating for 30 min at 37° C, the reactions were chilled and extracted twice with phenol equilibrated with 2 × SSC (0·3 M sodium chloride–0·03 M sodium citrate). The extracted RNA was precipitated from 2 × SSC at 0·1 M KCl by adding 2 volumes of 95 per cent ethanol and after 2·5 h at −10° C. The precipitate was collected by centrifugation at 10,000*g* for 60 min. The invisible pellet was resuspended in 0·2 ml. 2 × SSC, extracted twice with ether, and bubbled with nitrogen. Each annealing reaction mixture (200 μl.) contained a marked 1/8 sector of a 25 mm 'Millipore' filter, each sector bearing 0·3 μg *E. coli* denatured DNA. Different quantities of the *in vitro* RNA were annealed for 18 h at 67° C in 2 × SSC + 5 per cent dimethylsulphoxide together with 0·02 μg ^{32}P rRNA. After annealing the filter sectors were combined in a test tube and washed by agitation with 5 × 5 ml. 2 × SSC. 2 ml. 2 × SSC and 200 μg ribonuclease A (previously heated to 95° C in dH_2O) were then added and the sectors were kept at room temperature for 1 h. The filter sectors were then rinsed five more times with 2 × SSC, dried and counted. Non-specific binding of rRNA to filters is about 2 per cent of the saturation of 3,000 c.p.m., and at saturation about 5 per cent of the input radioactive RNA hybridizes. ●—●, The amount of ^{32}P-rRNA hybridizing in the presence of increasing quantities of *in vitro* product; ○- - -○, the ^{32}P-rRNA hybridizing when 0·2 μg of rRNA was added to the *in vitro* synthesis reaction.

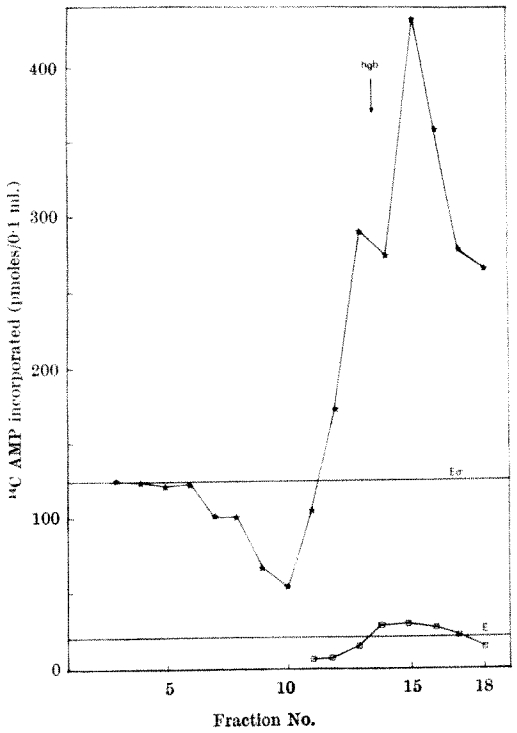

Fig. 2. Zone sedimentation of a ribosome free crude extract. 1 g *E. coli* strain RFS 524 was suspended in 1 ml. 0·01 M Tris-HCl (*p*H 7·9 at 25° C), 0·0001 M dithiothreitol, 0·005 M EDTA, 300 μg/ml. lysozyme and 5 per cent glycerol. The cells were frozen and thawed twice and 2 ml. 0·01 M Tris-HCl (*p*H 7·9), 0·01 M $MgCl_2$, 1·0 M KCl, 0·0001 M dithiothreitol, and 5 per cent glycerol were added to the crude lysate with gentle mixing. Ribosomes together with the bulk of the DNA were removed by centrifugation for 2 h at 100,000*g*. 500 μl. of the clear supernatant was layered on a 12 ml. linear 10–30 per cent glycerol gradient containing 0·01 M Tris-HCl (*p*H 7·9), 0·01 M $MgCl_2$, 0·5 M KCl, 0·0001 M EDTA, and 0·0001 M dithiothreitol. The gradients were centrifuged for 24 h at 41,000 r.p.m. at 7° C in an 'SW 41' rotor. 0·06 ml. fractions were collected and 20 μl. aliquots of the fractions were assayed for factor activity as described in the legend to Table 1. The activities of core polymerase (E) and complete enzyme (Eσ) on *E. coli* DNA without added fractions are shown as base lines. The depression of activity sedimenting at about the 8S region is probably due to the termination factor, ρ[18].

revealed a broad peak of stimulating activity sedimenting at ~3S (Fig. 2). Furthermore, these same fractions possessed no significant RNA polymerase activity of their own and only negligibly stimulated core enzyme. Thus the stimulating activity is not a new polymerase nor a sigma factor. The failure to stimulate core polymerase suggests that it is not a non-specific nuclease which would be expected to stimulate core polymerase by generating nicks in the DNA template[11].

The observed stimulation of RNA synthesis represents the synthesis of a specific class of RNA species rather than merely a general increase in activity. Competition of labelled RNA synthesized *in vitro* in the presence of Ψ_r demonstrated (Fig. 3*a*) that rRNA synthesis was stimulated very strongly. About 30 per cent of the RNA synthesized *in vitro* in the presence of the peak stimulating fraction was competed by rRNA, whereas no detectable rRNA was synthesized by RNA polymerase complete enzyme alone. In this experiment rRNA accounts for about half of the total stimulation of RNA synthesis. We have not yet determined the nature of the other RNA species stimulated. Thus rRNA synthesis requires, in addition to the RNA polymerase complete enzyme, another factor(s) which we have called Ψ_r. These experiments have shown that this factor can stimulate rRNA synthesis at least one hundred and fifty-fold *in vitro*.

Further purification of this crude Ψ_r fraction has not yet been attempted because, as shown below, we discovered that Ψ_r activity is also manifested by a component of Qβ replicase.

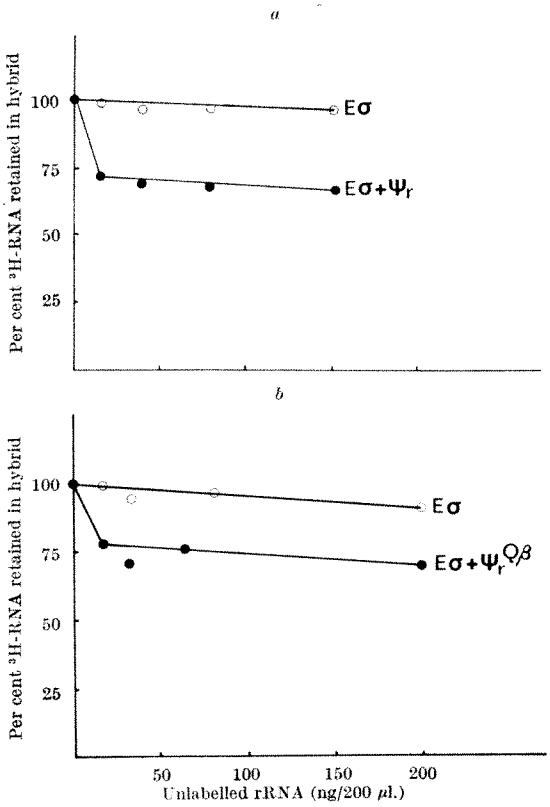

Fig. 3. *a*, Hybridization competition of *in vitro* ψ_r stimulated ³H-RNA by rRNA. *E. coli* ³H-RNA was synthesized *in vitro* in the presence and absence of fraction 15 of the gradient shown in Fig. 2. The reaction mixtures contained in 200 μl. 0·02 M Tris (*p*H 7·9), 0·10 M KCl, 0·01 M $MgCl_2$, 0·006 M 2-mercaptoethanol, 0·15 mM CTP, GTP and UTP, 0·04 mM ³H-ATP at 2·5 Ci/mmole, 75 μg/ml. *E. coli* DNA, 30 μg/ml. RNA polymerase complete enzyme and 200 μl./ml. of fraction 15 as appropriate. The reactions were terminated after 10 min at 37° C by the addition of SDS to 0·05 per cent. Water saturated phenol was then added and, after centrifugation, the resulting aqueous layer was used as the source of ³H-RNA. Aliquots of ³H-RNA were annealed in 2×SSC for 5 h at 66° C with 6 μg/ml. denatured *E. coli* DNA, and the indicated amount of unlabelled rRNA. The reaction mixtures (200 μl.) were then chilled and incubated with 10 μg/ml. heat treated ribonuclease A for 45 min at 25° C. They were filtered on Schleicher and Schuell 'B6' filters, rinsed with 30 ml. 2×SSC, dried and counted in toluene–liquifluor. ○, Competition of RNA synthesized by complete enzyme alone—input 34,200 c.p.m.; RNA hybridized in absence of competitor (mean of duplicate samples), 3,013 c.p.m. ●, Competition of RNA synthesized by complete enzyme and fraction 15—input 62,710 c.p.m.; RNA hybridized in absence of competitor, 6,526 c.p.m. A background of 320 c.p.m. has been subtracted from all points. *b*, Hybridization competition of *in vitro* ³H-RNA synthesized in the presence of Qβ replicase smaller subunit. The reaction mixtures were as described in the legend to Fig. 2, except they contained 0·05 M KCl, 6 μg/ml. termination factor, 0·2 μg/ml. purified small subunits of Qβ replicase where appropriate. They were incubated for 15 min at 37° C. ○, Competiton of RNA synthesized by complete enzyme alone, input 28,320 c.p.m.; RNA hybridized in absence of competitor 2,212 c.p.m. ●, Competition of RNA synthesized by holoenzyme and small replicase subunits, input 43,990 c.p.m.; RNA hybridized in absence of competitor 3,560 c.p.m.

Ψ_r as a Component of Qβ Replicase

There may be a relationship between rRNA synthesis and RNA phage replication, because RNA phages R17 (ref. 12) and Z1K/1 (ref. 13) inhibit rRNA synthesis in a progressive manner between 10 min and 30 min after infection. Furthermore, both RNA phage replication[14] and rRNA synthesis[15] are subject to stringent control when *rel*⁺ cells are starved for an amino acid. One attractive explanation of these phenomena is that RNA phage replicases and DNA dependent RNA polymerase compete for a protein(s) which is necessary for both rRNA synthesis and phage RNA replication.

Kamen[16] and Kondo *et al.*[17] have shown that the RNA replicase induced in infected cells by RNA phage Qβ contains three host specific polypeptides. These specifically copurify with the single phage specific polypeptide, and are thought to be subunits of the replicase[16]. The two smaller host subunits (molecular weights of 45,000 and 35,000) have been separated from the two larger subunits[16]. The subunits were first tested for Ψ_r activity by assaying for stimulation of total RNA synthesis by RNA polymerase complete enzyme on *E. coli* DNA. The pair of smaller subunits but not the pair of larger subunits showed such activity while neither pair was active without complete enzyme (Table 1*a*). The smaller subunits specifically stimulated RNA synthesis on *E. coli* DNA—they had no effect on transcription by core polymerase alone and also failed to stimulate complete enzyme on phage T4 or T7 DNA (Table 1*b*).

The replicase subunits preferentially stimulate rRNA synthesis. In the presence of both of the small subunits and the RNA termination factor, ρ (ref. 18), about 20 per cent of the total RNA synthesized in 15 min at 37° C could be competed by rRNA (Fig. 3*b*). The synthesis of rRNA in the presence of ρ suggests that its transcription is not an artefact of "readthrough" from a contiguous region of the DNA. Interestingly, ρ preferentially decreased RNA synthesis stimulated by the replicase subunits (Fig. 4). This depression was observed both in the initial rate of reaction (measured as early as one min) and in the final extent of synthesis under ionic conditions (0·05 M) which do not allow reinitiation[19]. This result can be accounted for if a fraction of $\Psi_r^{Q\beta}$ directed initiations occur at short transcriptional units, such as those specifying tRNA. The presence of ρ would allow rapid termination and release of short RNA chains, preventing readthrough into adjacent genes (see, for example, ref. 18). Experiments to assess directly the role of $\Psi_r^{Q\beta}$ in tRNA synthesis are now in progress.

To illustrate the purity of the enzyme used in these experiments, SDS–polyacrylamide gels are shown in Fig. 5. The RNA polymerase contained subunits β, β′, σ, and α (ref. 20), while the stimulating fraction contained predominantly replicase subunits III and IV[16], but none of the 65,000 molecular weight phage specific subunit.

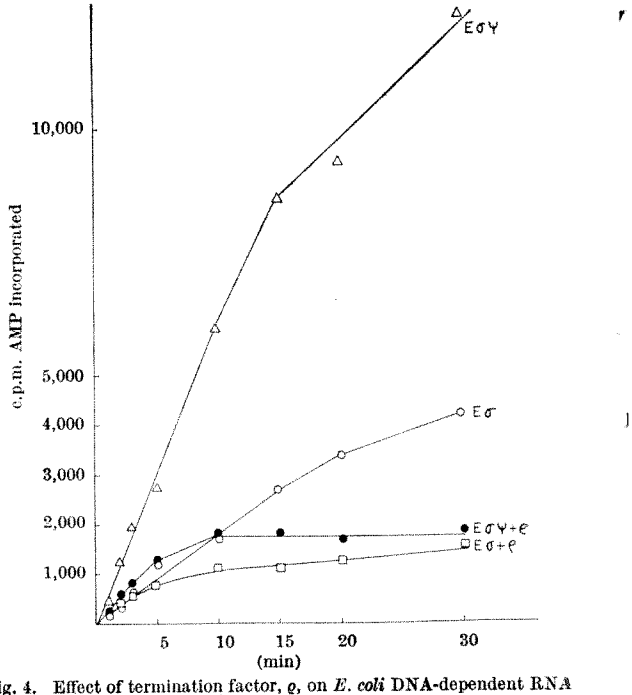

Fig. 4. Effect of termination factor, ρ, on *E. coli* DNA-dependent RNA synthesis with or without $\psi_r^{Q\beta}$. The reaction mixtures were as described in the legend to Fig. 3, except they contained 5 μg/ml. *E. coli* DNA, 15 μg/ml. complete enzyme, 8 μg/ml. $\psi_r^{Q\beta}$ and 6 μg/ml. termination factor, when indicated. The DNA was added to the incubation mixtures (at 0° C) last, the mixtures divided into 50 μl. aliquots, and then incubated at 37° C for the indicated times. Reactions were terminated by the addition of 3 ml. 5 per cent TCA, 0·01 M sodium pyrophosphate, 1 M NaCl, filtered through Millipore 'DA' membrane filters, washed five times with 3 ml. of the same TCA solution, once with 95 per cent ethanol, and then dried and counted in toluene–omnifluor scintillation fluid. A zero-time blank, measured from a sample which was kept at 0° C until precipitated, of 30–60 c.p.m., is subtracted in each incorporation curve.

Table 1. TEMPLATE SPECIFICITY OF Ψ_r STIMULATED RNA SYNTHESIS

(a)

Enzyme	Template	c.p.m. AMP incorporated
Complete enzyme (Eσ)	*E. coli* DNA	1,089
Complete enzyme + replicase subunits III + IV		1,932
Complete enzyme + replicase subunits I + II		1,132
Replicase subunits III + IV		7
Replicase subunits I + II		5

(b)

Enzyme	Template	c.p.m. AMP incorporated minus ψ	plus ψ
Complete enzyme (Eσ)	*E. coli* I	556	1,094
	E. coli II	987	1,830
	T4	5,410	4,784
	T7	7,349	6,385
Core (E)	*E. coli* I	172	171
	E. coli II	260	258

The reaction mixtures were as described in the legend to Fig. 3, except they contained 0·05 M KCl, 0·15 mM ^{14}C-ATP at 35 Cl/mole, 0·2 μg/ml. purified small subunits of Qβ replicase, 15 μg/ml. complete enzyme or 18 μg/ml. core polymerase as appropriate. The DNA templates used are as indicated. Incubation was for 10 min at 37° C. The reaction was stopped by the addition of 3 ml. 5 per cent TCA containing 0·01 M sodium pyrophosphate, and the RNA precipitate resulting was filtered on a 'Millipore' 'DA' filter. The filters were washed, dried and counted in a gas flow counter at a counting efficiency of 35 per cent.

Thus an activity functionally similar to the crude Ψ'_r factor activity was observed in a highly purified defined system.

Both in the specificity of stimulation and in the fraction of rRNA stimulated the activity of the two smaller replicase subunits resembles that of the crude Ψ'_r fraction. We have no evidence whether one or both of the replicase subunits is required for factor activity, nor do we have direct physical evidence that either of the replicase polypeptides is identical to the active entity in the crude preparation.

The method of preparation of Ψ'_r from uninfected cells is similar to that employed by Davison *et al.*[21] for identification of M factor, a transcription factor sedimenting at 4S which stimulated RNA synthesis by both core polymerase and holoenzyme on a variety of DNA templates. Ψ'_r is, however, clearly different from M-factor both on the basis of template specificity and of their relative abilities to stimulate transcription by core polymerase.

Mechanism of Action

What is the molecular mechanism of the action of Ψ'_r? There are two simple possibilities. Ψ'_r could either interact initially with the DNA at or close to the rRNA promoter site, or it could initially bind to the RNA polymerase complete enzyme to form a ternary complex which acted as the recognition unit for promoters under Ψ'_r control. The latter seems more likely because $\Psi'^{\sigma}_{r\beta}$ interacts directly and functionally with the other polypeptide chains of Qβ replicase. Furthermore, a mixture of replicase subunits III and IV will not bind poly C (as detected by retention on nitrocellulose filters), while subunits I + II or intact replicase will bind the polymer (unpublished observations of R. I. K.). This suggests that $\Psi'^{\beta}_{r\beta}$ (subunits III + IV) does not interact with poly C even though it is required for RNA synthesis by Qβ replicase with this template[16]; in a parallel fashion it seems likely that

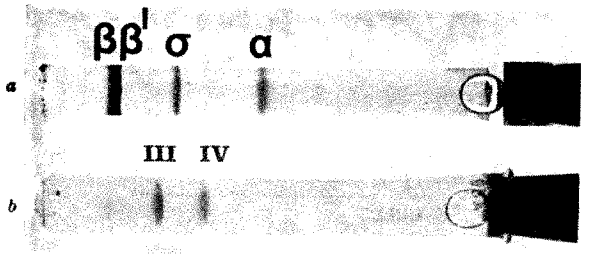

Fig. 5. SDS-polyacrylamide gels of RNA polymerase and Qβ replicase smaller subunits. *a*, Approximately 8 μg RNA polymerase complete enzyme run on a 5 per cent gel as described by Weber and Osborn[26]. The enzyme contained (from left to right in the photograph) subunits β, β', σ and α, with less than 1 per cent of any other polypeptide. *b*, Approximately 3 μg replicase host subunits III and IV, run on a 10 per cent gel. A small amount of replicase host subunit I is barely visible (< 5 per cent) but no other component can be detected (< 1 per cent).

Ψ'_r stimulation of transcription is mediated by interaction with the RNA polymerase rather than with the DNA.

Control of Transcription in Bacteria

The similarities between Ψ'_r and CAP[9] are striking. Both are thought to be involved in the specific initiation of particular classes of RNA. They are approximately the same size and they both require sigma function. Further, they are both functionally involved in transcriptional processes controlled by a nucleotide, CAP activity being activated by cyclic 3′,5′-AMP and Ψ'_r function, as we will show (A. A. T., R. I. K. and Cashel, manuscript in preparation) being inhibited by ppGpp.

The parallels between Ψ'_r and CAP suggest the provocative possibility that these factors are representative of a class of bacterial positive control elements which we propose be generally termed psi (Ψ') factors. The existence of such factors implies that a hierarchy of recognition elements for the initiation of RNA synthesis might operate *in vivo*. Sigma factors are the primary determinant for promoter recognition. The Ψ' factors would act as secondary specificity determinants allowing the RNA polymerase with sigma but not the core polymerase to transcribe general classes of transcription units, each Ψ' factor being specific for a given class. In this context it is worth noting that a mutation of the *lac* promoter apparently relives the requirement for the CAP factor[22]. The regulation of Ψ' factors by low molecular weight effectors provides a system of control that is readily reversible and which would allow the bacterial cell to respond rapidly to environmental changes. Changes of a more irreversible nature, however, such as those associated with sporulation in *B. subtilis* or with lytic phage development involve such phenomena as modification of the core polymerase[23,24], the appearance of a phage induced transcription initiation factor[7,8], or even the *de novo* synthesis of a new RNA polymerase[25].

We thank Professor James D. Watson and Professor Walter Gilbert for their support and advice; and Mr Alan Maxam, Miss Judith Karelitz and Miss Marilyn Magazin for technical assistance. A. A. T. is a postdoctoral fellow of the Damon Runyon Memorial Fund for Cancer Research, R. I. K. is a predoctoral fellow of the National Science Foundation, and R. F. S. is a postdoctoral fellow of the Helen Hay Whitney Foundation.

Correlated Subpulse Structure in PSR 1237 +25

by
D. C. BACKER]
Cornell-Sydney University Astronomy Center,
Arecibo Observatory, Arecibo, Puerto Rico

PSR 1237+25 has a short-period subpulse system in which subpulses march in a sense opposite to that found in other pulsars and a long-period system which is strongest in the midpulse region where the short-period system disappears.

THE Fourier analysis method of quantifying the class two phenomenon in PSR 1919+21 (ref. 1) has been applied to a sequence of pulses from PSR 1237+25. The results are: (*a*) The two features which appear in a fluctuation power spectrum of a sequence of pulse energies at $P_3 = 0{\cdot}354$ cycles per pulse period (c/P_1) and at $P_4 = 0{\cdot}021$ c/P_1 (ref. 2) are found to arise from variations of different components of the average pulse profile. The latter occurs in the central region of the profile, while the former occurs in the outer regions. (*b*) The variation with position in the pulse profile of the phase of the short-period feature (P_3) in the spectra of energies formed with a narrow time gate shows that the feature is due to correlated subpulse structure in short sequences of pulses. It also indicates that the subpulses evolve in a reverse manner to that found in the five other pulsars in which the detection of the phenomenon has been reported[3-5]; that is, the subpulses are correlated from pulse to pulse at progressively later points within the pulse profile. (*c*) The variation with position in the profile of the phase of the long-period feature (P_4) is difficult to interpret but suggests that this feature is due to an independent system of correlated subpulses. (*d*) The frequent and narrow type II pulse nulls which occur in this object and which are described in ref. 6 are found to arise from a subpulse spacing (P_2) which is broader than the width of those components in the average profile which participate in short-period events. (*e*) The wide and infrequent type I nulls, which are also described in ref. 6, are weakly correlated with the long-period feature (P_4) in the spectra. The data also show that these type I nulls are only occasionally associated with a phase discontinuity of the short-period subpulse evolution as has been shown for a similar null phenomenon in PSR 0808+74 by Huguenin *et al.* (unpublished). The data are insufficient for more definite conclusions about the relations between the long-period feature, the type I nulls and the short-period feature.

The possibility of both forward and backward marching subpulses supports pulsar models where a group of charges which is responsible for the emission is retained from pulse to pulse and is only partially decoupled from the clocking mechanism. The symmetry of the phenomena taking place across the pulse profile supports models with a hollow cone of emission which sweeps across the observer's line of sight. The existence of two systems of correlated subpulses may indicate that both ionic components of a plasma are active in separate regions of the objects.

Observations

The data were obtained as in ref. 1. In this case the receiver parameters were an observing frequency of 607·5 MHz, linear polarization, a bandwidth of 1·0 MHz and a post detection time filter of 1·0 ms. A time filter was used to reduce the correlation between samples which would be present using *RC* time constants with strong pulsed radiation. The radiation intensity was sampled every millisecond over a window of 200 ms centred on the pulse. A new method of synchronizing the sampling window with the pulsar apparent frequency ($1/P_1$) was used. This method uses the radar timing equipment available at the observatory and allows the repetition frequency of the synchronizing trigger pulse to be updated during a run to allow for variations in the pulsar apparent period due to the Doppler effect of the Earth's rotation. By this means the pulsar radiation can be sampled synchronously to within a fraction of a millisecond over a full observing period of 2½ h.

Fluctuation Power Spectra

Fig. 1 presents the digitally recorded data as deflexions from a consecutive pulse number axis which are proportional to the full pulse energies, or the integral of the samples on the pulse less the integral of the same number of samples off the pulse. The first 512 pulses were used in

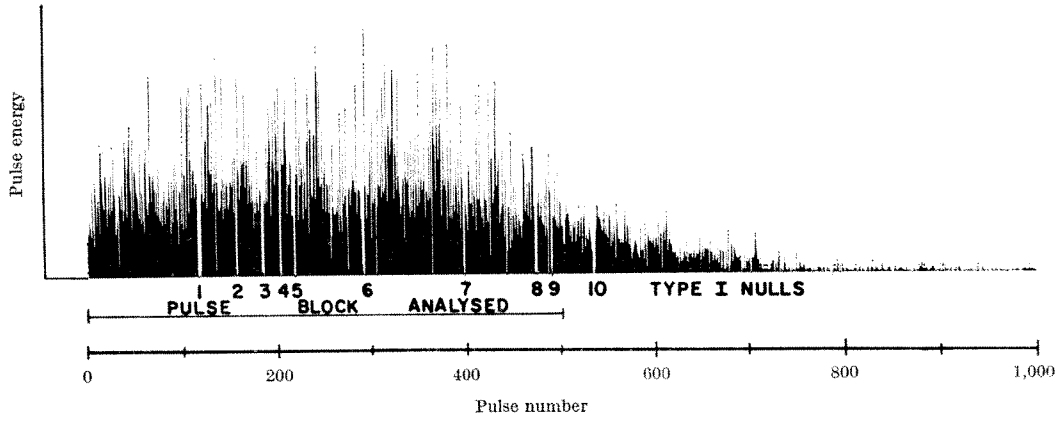

Fig. 1. Pulse energies from observation of PSR 1237+25 on May 17, 1970, presented as deflexions from a pulse number axis (the abscissa). The block of pulses used in the analysis described in the text and the location of type I nulls defined in ref. 6 are noted.

the analysis which will be described below. A fluctuation power spectrum formed from the Fourier transform of this block of full pulse energies confirmed the details of the spectrum which were noted by Lang[2]. His average spectrum is dominated by a very low frequency tail, due presumably to interstellar scintillations, but also contains a short-period feature (SPF) at $P_3 = 0{\cdot}354$ c/P_1, and a long-period feature (LPF) at $P_4 = 0{\cdot}021$ c/P_1.

A power spectrum analysis was then done using the data in a narrow time gate, or longitude box (LB*), for each pulse. Analysis I formed 23 spectra for 23 LBs, each containing three samples (3 ms or 7°·8 of longitude), across the pulse width. Analysis II, which was performed to increase the resolution, used a gate of one sample (1 ms or 2°·6 of longitude) for 61 LBs. The mean level for each LB in analysis II, or the average pulse profile, is shown in Fig. 3*a* with the positions of the 23 LBs of analysis I marked. This average profile as well as those from other observations indicate the presence of five components which have been numbered in Fig. 3*a* from the leading edge to the trailing edge. Components IV and V are unresolved in this average, but are distinct in others.

The fluctuation power spectra from analysis I are presented in Fig. 2. The spectra were formed from the incoherent sum of the power coefficients of two transforms of 256 pulses each and from taking a running mean over five coefficients. The linear scales are dependent on the maximum frequency component in each spectrum. Thus for LBs where the mean level is small, the spectral noise appears large. The zeroes are displaced uniformly. The SPF is very strong, dominating the very low frequency tail, in LBs 3 to 6 and again in LBs 20 to 22. The LPF is equally as strong in LBs 12 to 15. This immediately suggests that the average profile is a composite of independent components. This will be discussed later.

In order to untangle how the average pulse profile is constituted statistically, several quantities were defined and measured. The variation of these quantities with LB is presented in Fig. 3*b* to *e*. For each of the features three quantities were defined as in ref. 1. The "strength" was determined from the integral of the spectral power in the feature above the level of the white component by taking the square root of the integral and dividing by the mean level. The regions of integration for the LPF, SPF, and white component are indicated in Fig. 2. Second, the centre frequency was defined to be the point where half of the power in the feature occurs on either side. Finally, the phase of the spectral component at the centre frequency was determined from the complex coefficients. In this analysis the phases from the two transforms for a given component were added modulo 360°.

The level of the white component in the spectra was defined as the square root of the ratio of the average power in the signal spectra away from the features to the average power in the noise spectra. The modulation index was determined from the square root difference between the integral of the power in the signal spectrum and the integral of the power in the noise spectrum divided by the mean level squared.

Discussion

The variation with LB of the strength of the SPF from the spectra in analysis I (Fig. 3*c*) indicates that only components I, II, IV and V participate in the short period events. The SPF centre frequency (Fig. 3*c*) is constant in components I and V and is offset slightly in components IV and V. The phase function for the frequency 0·363 c/P_1 determined from the spectra in analysis II (Fig. 3*c*) displays a high degree of correlation from one LB to the next in the regions where the SPF is strong. Throughout these two regions the phase evolves slowly.

* The term "longitude" is introduced in place of "pulse phase" which was used in ref. 1 because dual usage of the word phase is confusing and because many authors are referring to the phase in a pulse period as longitude.

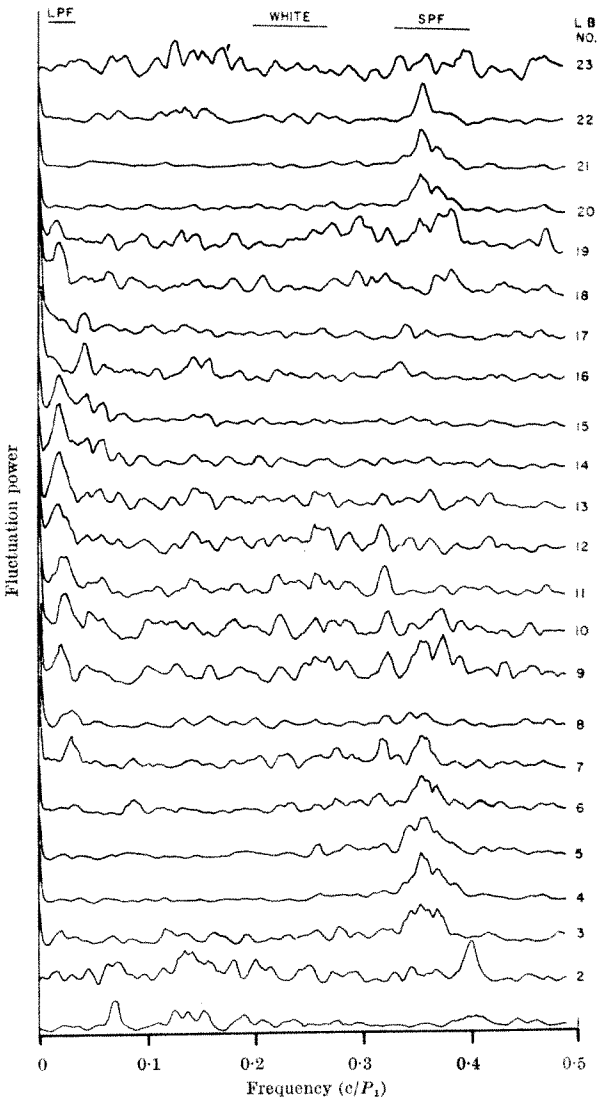

Fig. 2. Fluctuation power spectra of pulse energy for a narrow time gate for 23 longitude boxes (LBs) across the pulse profile. The linear scales for each spectrum vary according to the maximum power coefficient and zeroes for each are displaced. The regions of the long-period feature (LPF) and short-period feature (SPF) are noted as well as a region used to determine the level of the white component in the signal spectra.

It is increasing slowly across component I and decreasing in component II. When the correlation reappears near LB 15, the phase is at first decreasing across component IV and then approaching a constant in component V. As demonstrated in ref. 1 for 1919+21, this correlation of the phase indicates the presence of a class two phenomenon with the gradient of the phase with LB being a measure of the average subpulse spacing P_2. The negative gradient shown in Fig. 3*c* thus implies that the subpulses are correlated from pulse to pulse at progressively later positions within the pulse profile. Qualitatively this phase function then indicates that subpulses arise between components I and II, move rapidly through component I to the leading edge with $P_2 = 34$ ms and slowly through component II towards the trailing edge with $P_2 = -7$ ms (the minus sign denotes a negative gradient in the phase function and therefore the fact that new subpulses appear at earlier points within the pulse profile). In the midpulse region (component III) the subpulses cannot be followed because, for some reason, their strength diminishes to zero. On the trailing edge (components IV and V) an acceleration to the trailing edge occurs with $P_2 = -4$ ms in component IV and P_2 decreasing indefinitely (towards $-\infty$) across component V.

Because the SPF arises in a similar manner in components I, II, IV and V, and because the values of P_2 in components II and IV are similar, it is likely that these components are closely related physically and that some independent effect causes the observed variations in the SPF strength. In fact, the strength and phase functions of the SPF suggest that components IV and V are in some sense mirror images of components I and II with the mirror centred on component III.

It is interesting to compare at this point the SPF strength and phase function for 1237+25 with the to 2·78 lines, or pulses. The phase in the midpulse region was drawn slowly decreasing on the basis of the phase functions for adjacent frequency components which showed more correlation. Individual subpulses are seen to evolve along the average path given by this phase function, especially in the region of component II, although the intricacies of the function and the pulse profile are confusing. The phase of individual subpulse paths relative to the overlay is seen to fluctuate up to 360°, as has been noted for other pulsars[3,4].

Interpretation of the LPF is difficult as the block of

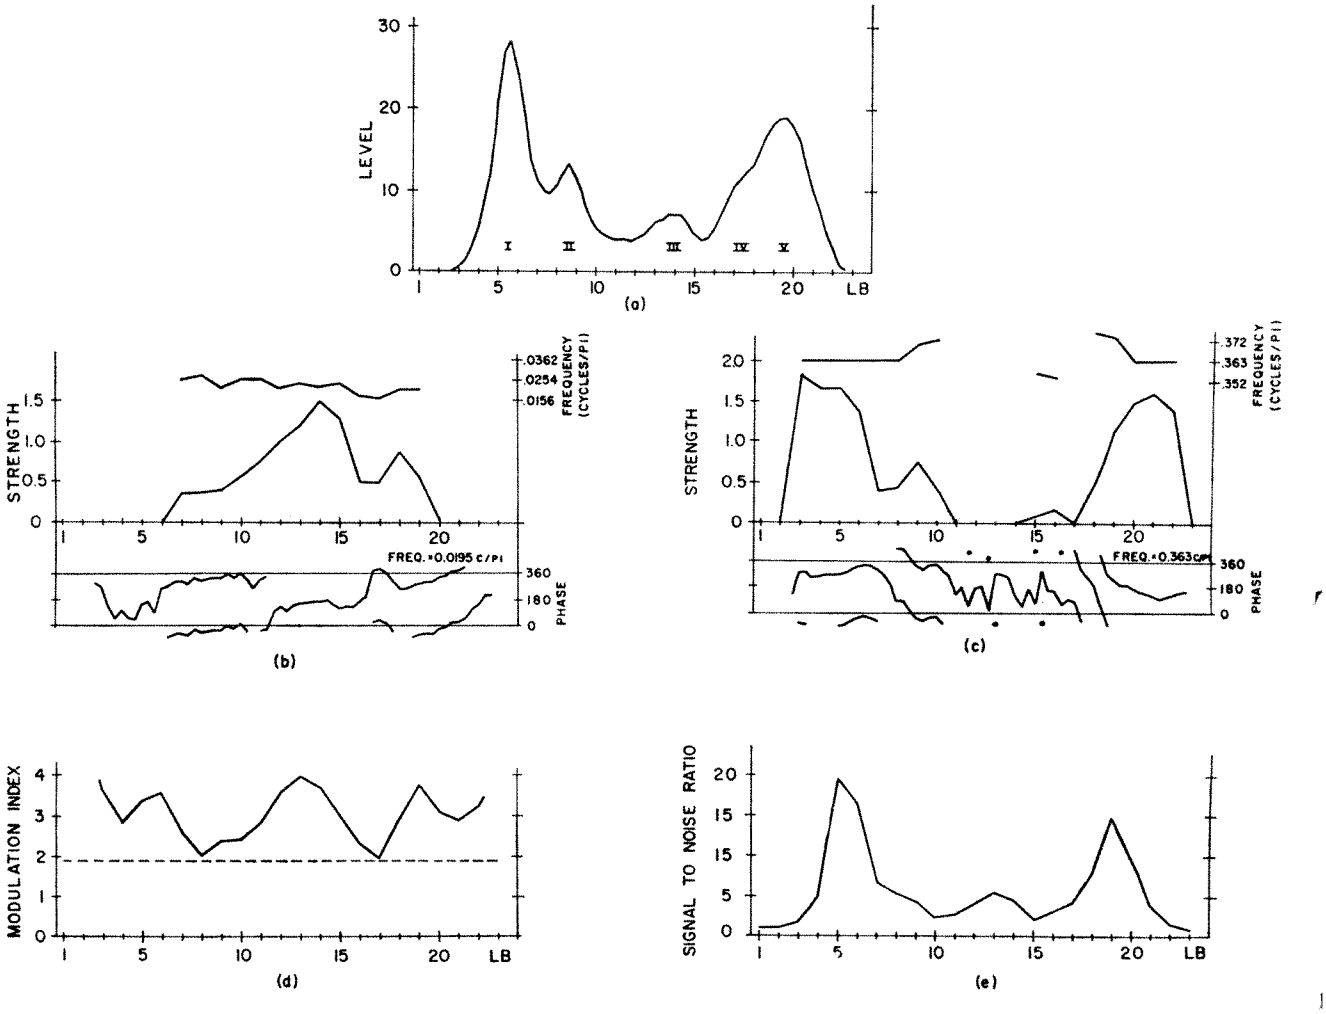

Fig. 3. Summary of the spectra from analyses I and II described in the text. *a*, The mean levels from the spectra in analysis II. Five components of the average profile are noted. *b*, Strength, centre frequency and phase of the long-period feature as defined in the text. The phase function is plotted between −90° and +450°. *c*, Strength, centre frequency and phase of the short-period feature analogous to *b*. *d*, The modulation index for the spectra in analysis I. *e*, The ratio of the level of the white component to the noise (as defined in the text) from analysis I.

corresponding results for 1919+21 (ref. 1). Both have strength functions which are peaked on the leading and trailing edges of the average pulse profile and both have phase functions which flatten out ($|P_2|\to\infty$) at the leading and trailing edges. Although the profiles of the two objects are vastly different, the 1919+21 profile is dominated by a steady component while 1237+25 is not. If this were removed, the profiles would be similar.

To see if the raw data confirm this complex average behaviour an overlay of the phase function smoothed from Fig. 3c and repeated every $P_3=2{\cdot}78P_1$ was placed on a computer printout of the intensity as a function of sample number in the window on a single line and sequential pulse number for successive lines (Fig. 4). The overlay was scaled such that 360° of phase was equal 512 pulses contains only ten full periods of the oscillation. It can be seen in the data that component III is active for only a few pulse periods at infrequent intervals. The large increase in the modulation index in the region of component III (Fig. 3*d*) is a result of this intermittent behaviour. The LPF indicates that the intervals between activity are periodic. The spectrum of a periodic phenomenon with such a low duty rate should contain many harmonics of the fundamental frequency. This indeed is the case as may be seen in Fig. 2. The spectra for LBs 14 and 15 definitely show several harmonics of the LPF, while the spectra for LBs 16 and 17 show the second harmonic as the dominant feature. The latter is related to the dip in the strength and the shift in the centre frequency of the LPF for these LBs (Fig. 3*b*).

The LPF phase function (Fig. 3*b*) shows the phase of the 0·0195 c/P_1 component of the spectra in analysis II increasing slowly across component III where the feature is strongest. This indicates the presence of correlated subpulse structure in long sequences of pulses. The low duty rate of component III mentioned here is thus a result of a second system of subpulses which are particularly strong in component III. The exact path along which they evolve is not well determined from the phase function presented here because the centre frequency of the feature varies by 25 per cent across the pulse. This variation introduces gradients in the phase function not due to evolving subpulses. This is particularly evident between LBs 14 and 18. There the harmonic content in the spectra increases and eventually dominates the LPF fundamental and the phase function of the fundamental wanders. In conclusion, the interpretation is consistent with the data but must be considered tentative.

Finally, the signal-to-noise ratio of the white component in the spectra (Fig. 3*e*) is found to follow the pulse profile level closely. This implies that the amplitude of pulse-to-pulse random variations of the grated energies is proportional to the mean level.

Pulse Nulling Phenomena

Pulse sequences from this pulsar contain two types of pulse nulls[6]. As described in ref. 6, type I nulls last for several pulse periods and occur infrequently while type II nulls are frequent, single pulse nulls. The positions of type I nulls in this block of data are shown in Fig. 1 and examples of both types of nulls are located in Fig. 4. On the basis of the overlay in Fig. 4, the type II nulls can be explained by the occurrence of two successive evolutionary paths of subpulses with a phases of plus and minus 180° referred to the null pulse. When this occurs, components I and V in the preceding and (or) following pulses are active and little energy is detected in the centre pulse.

The type I nulls are often associated with a strong component III following the null, but nulls 5 and 6 in Fig. 4 show that this rule does not occur without exception. Also the type I nulls are occasionally associated with a phase discontinuity of the evolving subpulses. In Fig. 4 at the type I null number 5 the phase was disrupted slightly while at number 6 it remained coherent.

Interpretation

Although this object shows very complex behaviour, the analysis indicates that there is a good chance that it can be unravelled. The independent effect which modulates the SPF subpulse system so that we see two pairs of components may be the geometry of a rotating beam crossing our line of sight. The apparent mirror image effect of these pairs is particularly suggestive of the pulsar models where the radiating region produces a hollow cone of emission[7] at the pole of a strong magnetic field on a rotating neutron star which swings across our line of sight. Manchester[8] finds that components I, II, IV and V show a high degree of linear polarization with a constant angle. His interpretation of the constant angle result is that our line of sight passes through the centre of a cone of emission from a magnetic pole. This is consistent with the results presented here.

The forward marching subpulses in this object remove the asymmetry that up to now has been observed in other objects. The correlation that exists between the subpulse structure in successive pulses suggests, but does not imply, that a group of charges responsible, in some manner, for the emission is retained from pulse to pulse. Either they are radiating themselves, or they are stimulating radiation.

The occurrence of a second subpulse system in the centre of the 1237 + 25 profile with a long repetition period P_4 could be interpreted as an effect of a second component of the plasma that is active in this object. It is suggested that the short period system is due to electrons and the long period system is due to ions. Other interpretations are certainly possible, but it is interesting that Sturrock[9] has proposed a model for short period pulsars such as 0532+21 based on a rotating, magnetic neutron star which has two cones of emission due to an electron polar zone surrounding a proton polar zone. According to his calculations, however, the proton polar zone would not be active in pulsars with 1 s periods due to energy considerations.

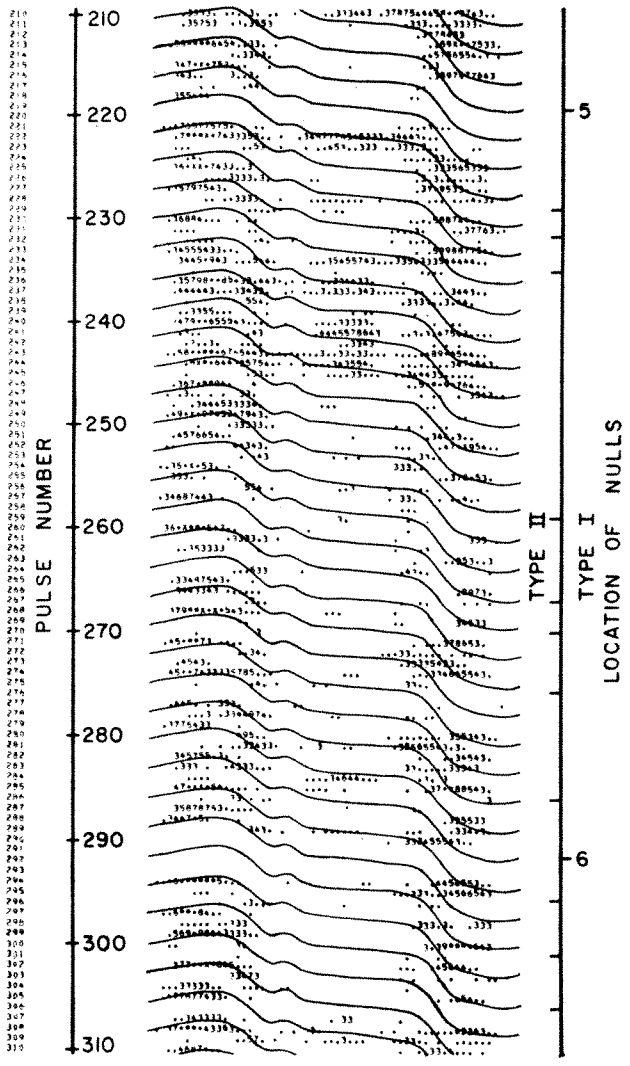

Fig. 4. Computer printout of pulse intensity across the window on a single line for 101 pulses used in the analysis. The phase function of the short-period feature from Fig. 3*c*, smoothed and repeated as described in the text, is drawn over the printout. The locations of type I and type II pulse nulls are noted.

The Arecibo Observatory is operated by Cornell University under contract with the National Science Foundation and with partial support from the Advanced Research Projects Agency. This work has been partially supported by the Air Force Office of Scientific Research.

ESRO Mission Definition Group on the X-ray Astronomy Satellite,
ESRO,
114 Avenue de Neuilly,
92 Neuilly-sur-Seine

A proposal for a European X-ray astronomy satellite includes a lunar occultation technique for the more accurate observation of new and existing X-ray sources.

AFTER eight years of research with small rocket and balloon borne payloads, X-ray astronomy currently embraces some fifty discrete sources ranging in intensity from the remarkably bright Sco X-1 source (40 photons cm^{-2} s^{-1} above 1 keV) to the present observational limit near 0·1 photon cm^{-2} s^{-1}. Unfortunately only eight sources have so far been identified with reasonable certainty and the majority of source positions, to one or two degrees, remain much too crude to allow this number to be increased significantly. The variety of the identified sources, comprising three supernova remnants, two peculiar yet visibly faint galactic stars, two strong extra-galactic radio sources and the brightest visible quasar, for each of which the association of a strong X-ray emission has added a new dimension to its apparent nature, emphasizes the primary importance of improved position determination—and hence the possibility of identification—in the future study of cosmic X-ray sources.

More Sources

The total of detected sources is expected to rise to several thousand following the launch later this year of the US X-ray Explorer, the first Earth satellite to devoted to X-ray astronomy and having a sensitivity threshold near 10^{-3} photon cm^{-2} s^{-1} in the kV energy range. This experiment will obtain position measurements accurate to 1′ for the stronger sources and to 10–20′ for those with photon intensity below 10^{-2} photon cm^{-2} s^{-1}, and should result in a considerable number of new optical and X-ray object associations. Yet, as Table 1 indicates, a reliable identification—on positional coincidence alone—will in many cases demand an accuracy of position to several arc seconds, particularly for X-ray sources at low galactic latitude. A similar precision is required for known X-ray sources, such as M87, CenA and the Crab nebula, to locate the region(s) of emission within the structure of the visible and radio counterpart.

Table 1. OPTICAL AND X-RAY OBJECT ASSOCIATIONS

X-ray source intensity above 1 keV (photons cm^{-2} s^{-1})	Number of X-ray sources	Corresponding visible magnitude, M_V	Density of stars of magnitude $\leq M_V$ (arc minute)$^{-2}$ $b^{II}=0$	$b^{II}=90°$
40	1	12·5	0·03	0·004
1	10	16·5	1·2	0·06
10^{-1}	100	19	8	0·2
10^{-2}	1,000 (?)	21·5	42	0·5

The positional accuracy required for an objective source identification is estimated from the density of visible stars having at least the brightness of the optical extension of the X-ray spectrum. This assumes the X-ray source to be optically thin bremsstrahlung of the Sco X-1 type and will underestimate the star brightness if additional cool gas is present and overestimate it in regions of significant dust obscuration.

Against the above background situation, we recently undertook the preliminary study of a European X-ray astronomy satellite with a projected launch in 1974/75. The results are reported briefly here and the proposed payload should shortly be the subject of a technical and cost assessment by the European Space Research Organization.

Occultation Technique

The arc minute accuracy of the X-ray Explorer and other early X-ray astronomy satellites, such as UK5 (to be launched in 1973), is essentially set by the inertial stability of the spacecraft itself. The achievement of a stability in the arc second range is both technically complex and extremely expensive. Thus, in the proposal described here, a lunar occultation technique is suggested, allowing considerable relaxation of the pointing control requirement. Instead, the limit to most source location measurements is set by the determination of the satellite position in space and this can be obtained much more easily and from a ground station. Fig. 1 shows the orbit of the ESRO HEOS A2 satellite which is known to be stable. The high eccentricity and large semimajor axis of this orbit extend the region of sky which is occultable well away from the ecliptic plane, thereby covering a greater number of source positions. A second advantage of the eccentric orbit is the very low angular velocity of the satellite near apogee, where the most precise measurements will be possible. Fig. 2 shows the region of sky occultable with the HEOS A2 orbit and it includes most of the Sco-Sagittarius sources and those in the Ara and Norma constellations, as well as the Crab nebula. It is unlikely that the HEOS A2 orbit is an optimum choice

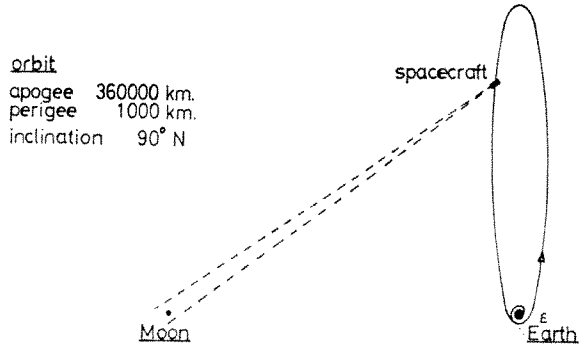

Fig. 1. Schematic of HEOS A2 orbit used to compute occultation area shown in Fig. 2.

for the suggested mission, and further studies could consider an increase in semi-major axis at the cost of payload weight, thereby extending the occulted region to the Centaurus sources. A second, or alternative, launch to the south of the ecliptic plane would then cover the remainder of the galactic centre sources, the Cygnus region and the important cluster of galaxies in Virgo.

Two successive orbits are drawn in Fig. 2 and it may be seen that they are separated by up to 5°. With a lunar diameter at the spacecraft varying from 0·3° to 0·5°, it will clearly be necessary to carry out orbital manoeuvres in order to occult a maximum number of chosen sources, these being known from earlier observations typically to a few arc minutes. An economical method of obtaining small changes in orbit position uses the same gas jet system envisaged for the main altitude control. The high velocity ejection of 0·2 kg of cold gas near orbit perigee can modify the satellite velocity by up to 1 m s^{-1}, causing a shift in the occultation path of several arc minutes in one day and up to several degrees after a month. Clearly it will be necessary to plan the observing programme carefully in advance in order to minimize the use of gas for a chosen number of source occultations. Such planning must also take into account the availability of ground based facilities, necessary for correlative observations.

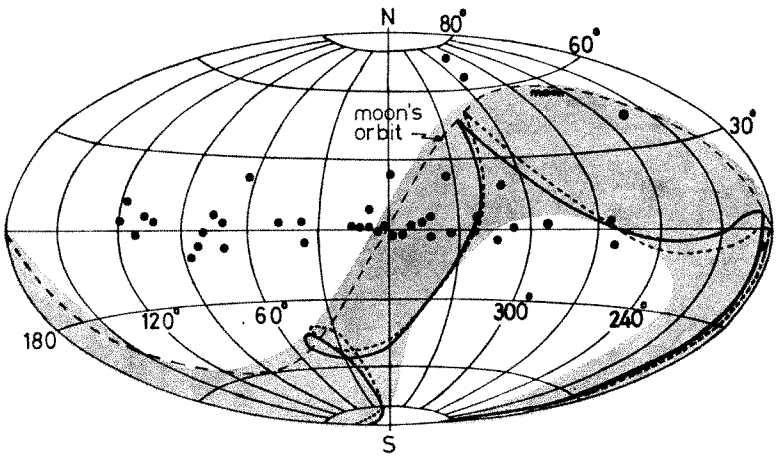

Fig. 2. Illustration in galactic coordinates of the area of sky (shaded) that may be occulted with the HEOS A2 orbit in one year of operation. Also shown are occultation paths of two successive satellite orbits and the distribution of known X-ray sources.

Factors affecting Accuracy

The accuracy of measurement possible with the occultation technique involves two principal factors, namely the determination of the spacecraft–Moon axis in astronomical coordinates and the X-ray counting statistics. For the former, the limit is clearly set by the measurement of spacecraft position and it is estimated that an accuracy of 1 or 2 km should be feasible, corresponding to an angular error subtended at the Moon of the order of 1″. The main X-ray detector in the satellite is envisaged as a conventional gas proportional counter, with effective window area 3,000 cm^2 and a sensitive bandwidth from 1 to 30 keV. A collimator mounted in front of the detector having a field of view of 2·5° (FWHM) will allow for the desired (moderate) lunar pointing accuracy, and will still limit severely the chance of a strong X-ray source other than the object source being viewed simultaneously and consequently adding significantly to the background counting rate. The satellite velocity in the nominal orbit varies from 0·25 km s^{-1} at apogee to 11 km s^{-1} at perigee, with corresponding angular rates of the occultation path from 0·5 to 5″ s^{-1}. It is therefore necessary to observe the disappearance (or reappearance) of an X-ray source within 2 to 0·2 s to achieve a positional accuracy of 1″. An estimate of detector performance, using typical values of efficiency and background counting rates, has shown that a 3σ variation should result from the occultation near apogee of a source of intensity 10^{-2} photon cm^{-2} s^{-1}. Stronger sources observed near apogee would then be limited by the satellite position error, and a similar statistical accuracy is predicted for sources three times stronger when observed near the satellite perigee.

The position measurement discussed above refers, of course, to the coordinate axis parallel to the path of occultation. In the transverse direction the angular distance of the source path from the centre of the Moon will be obtained from the period of occultation and this value will be less accurate than the longitudinal position for rather more than 50 per cent of all possible occultation paths. At worst, that is for a weak source (10^{-2} photon cm^{-2} s^{-1}) passing close to the Moon's centre, the transverse accuracy from a single observation will be of the order of 1′ and for such cases there will also be an inherent ambiguity of transverse position either side of the lunar diameter.

Higher Resolution

The second principal advantage of the occultation experiment lies in its ability to measure the size and structure of X-ray sources with a resolution unattainable by other means. Until now, only the overall extent of the Crab nebula source has been measured (~2′) and the upper limit of 20″ for Sco X-1 represents the best resolution achieved on any source. Many sources are likely to be much smaller than 1″ and extended sources may contain interesting structure on a comparable scale; in the proposed experiment the angular size of a source simply determines the rise or fall time of incident flux as the source crosses the Moon's limb. Table 2 gives the minimum angular dimension reliably measured for both strong and weak sources, near apogee and perigee, and there seems to be no reason why these figures should not be realized in practice. It should perhaps be noted that 10^{-3} arc second represents only 1 m in the lunar profile and thus quite small surface irregularities on the Moon and the finite extent of the X-ray detector may both modify the measured values for the stronger sources.

Table 2. MINIMUM ANGULAR SIZE DETECTED BY THE PROPOSED INSTRUMENT FOR A RANGE OF SOURCE INTENSITIES

X-ray source intensity (photons cm^{-2} s^{-1})	Minimum angular size detected (arc second) At apogee	At perigee
40	5×10^{-4}	5×10^{-3}
1	2×10^{-3}	2×10^{-1}
10^{-1}	3×10^{-1}	3·5
10^{-2}	25	250

In addition to the principal measurements of position, size and structure, the experiment will be capable of several other observations of sources that cross the field of view, whether occulted or not. A given source will remain visible for up to 4 h during a typical transit and the most useful additional study may be the search for short term variability in both intensity and spectrum (including periodic fluctuations). In the special case of X-ray sources associated with a known pulsar, it will be a relatively simple matter to phase analyse the X-ray counting rate using the known radio period and using a satellite clock. An estimated sensitivity of between 1 and 2 per cent pulsed component in a source of intensity 10^{-2} photon cm^{-2} s^{-1} should be obtained in a 3 h observation.

Aggregation of Nitrogen in Diamond

THIS note is an attempt to make quantitative the view[1] that it is erroneous that the impurity nitrogen in diamonds is mostly located in the platelets of diamonds.

The atomic percentage (N) of nitrogen in fifteen diamonds and the absorption coefficient (μ) at 1,282 cm^{-1} have been measured[2,3] by different techniques and are

$$\mu_{1,282} = (300 \pm 20)N \text{ cm}^{-1} \quad (1)$$

for

$$4 \times 10^{-3} < N < 2{\cdot}5 \times 10^{-1} \quad (2)$$

The only exception among the fifteen crystals was slightly inhomogeneous and had a small N. Sobolev *et al.*[1] found that the absorption coefficient at 1,368 cm^{-1} is proportional to the intensity of the X-ray diffraction spike that is caused by condensations, or platelets, in the cube planes[4]. The proportionality constant was not determined. Both these correlations hold over at least the ranges

$$1{\cdot}3 < \mu_{1,282}/\mu_{1,368} < 30 \quad (2, 3) \quad (3a)$$

$$0{\cdot}2 < \mu_{1,282}/\mu_{1,368} < 12 \quad (1) \quad (3b)$$

These data were taken on natural transparent diamonds apparently of types I*a* and II*a*. The rare type I*b* diamond (about 0·1 per cent of clear diamonds[5]) is assumed not to complicate the data.

It is known that there is a negligible concentration of paramagnetic isolated or almost isolated nitrogen in these types[6–8]. The bulk of the nitrogen must therefore exist in other forms such as in the platelets, in smaller aggregates, or in an isolated non paramagnetic form. We assume that the platelets contain nitrogen and, initially, that the nitrogen may exist in only one non platelet form. The correlations above may then be fulfilled subject to one of two conditions: either both the platelet and non platelet forms give absorption at 1,282 cm^{-1} in proportion to the number of atoms in those forms, or, if this is not so, one form of the nitrogen must account for the bulk of the nitrogen.

We consider first the former possibility. The strongest 1,368 cm^{-1} absorption on record[1] is about 25 cm^{-1} in a diamond with $\mu_{1,282} = 5$ cm^{-1}, implying, from (1), a total nitrogen content of 0·06 per cent. Hence the concentration of nitrogen in platelet form is, at most, $N_p = \mu_{1,368}/1{,}500$ per cent, where $\mu_{1,368}$ is measured in cm^{-1}. Then, for diamonds in which $\mu_{1,368} \sim 0{\cdot}5\ \mu_{1,282}$, as is often the case (see Fig. 2 of ref. 3), at most 10 per cent of the nitrogen is in platelet form.

The latter possibility can only satisfy (1) and (3) if the dominant form of the nitrogen is that giving the 1,282 cm^{-1} band. A figure may be put on the degree of domination required by noting that if a specimen has a 1,282 cm^{-1} absorption lower than that predicted by (1) we would ascribe the difference to the presence of nitrogen in platelet form. If the 1,282 cm^{-1} absorption measured is higher than (1), the difference must be due to experimental error. In no specimen has the 1,282 cm^{-1} absorption been measured significantly low (Fig. 4 of refs. 2 and 3) so that at the most the nitrogen in platelet form is 5 to 10 per cent of the total present, for the specimens within the limits of (3*a*) at least.

To distinguish between the two conditions it is necessary to know the absorption at 1,282 cm^{-1} per nitrogen atom for the two forms of nitrogen. Calculations are unreliable because no detailed models for the centres have been confirmed. The temperature independence of most of the impurity induced infrared bands[9] implies a lack of anharmonicity in the vibrational potential and hence uniaxial stress measurements are unlikely to determine the symmetry of the nitrogen forms. As observed in Si[10–13], different defects in diamond may stimulate the same perfect lattice modes. Thus all the neutron induced one photon bands[14] have the same shape and energy (although different relative intensities) as impurity bands in type I*a* diamond, many of which, in turn, may be associated with peaks in the perfect lattice density of phonon states[15]. Some bands in Si[10–13], however, are characteristic resonances of a defect. This characterization is shown in diamond by the failure of irradiation damage to create either the 1,282 cm^{-1} or the localized 1,368 cm^{-1} band[14]. So, although in principle the platelets could vibrate at 1,282 cm^{-1} with an absorption satisfying equation (1), it is unlikely.

We have demonstrated that existing data show that at least 90 to 95 per cent of the nitrogen in diamonds satisfying equation (3*a*) is in an unknown non platelet form if, as seems likely, the platelets cannot give absorption at 1,282 cm^{-1}. If the platelets do absorb at 1,282 cm^{-1} then the fraction of nitrogen in platelet form is at most $0{\cdot}2\ \mu_{1,368}/\mu_{1,282}$ and the non platelet form is again usually dominant. This still leaves sufficient nitrogen to be present in many other forms, including platelets at their known concentration[16]. The arguments given may be readily generalized to allow for several aggregated forms, but the conclusions are unaltered.

Correlations between Earth's Gravitational and Magnetic Field

IN a recent communication Hide and Malin[1] studied the similarities in the variations of Earth's gravitational and magnetic fields in an effort to determine the undulations on the core-mantle interface. These undulations, if present, can produce significant distortions in the geomagnetic field as it is observed on the Earth's surface[2,3]. These bumps will also distort the gravitational field.

Hide and Malin[1] confined their attention to displacements of magnetic pattern in longitude alone and observed a high degree of correlation between the two fields requiring a displacement of the magnetic pattern 160° to the east. I extend their studies here by considering displacements in latitude. This study will require transforming spherical harmonic series from one polar axis to another.

A rotation can be completely specified by the angle of rotation and the axis about which it takes place. An arbitrary rotation may be represented as a product of rotations. A set of all such rotations forms a group and is completely defined by a matrix. Consider a rotation about ox through an angle $\bar{\theta}$ and rotation about oz through angle $\bar{\varphi}$. Donating the matrices corresponding to each of these rotations by T_φ, T_θ, produces[4]

$$T_g = T_\varphi T_\theta \tag{1}$$

Rotation of spherical harmonic series about the axis ox and oz leads to[4]

$$T_g = \mathrm{e}^{-im\bar{\varphi}}\, u_n^m(\bar{\theta}) \tag{2}$$

where

$$u_n^m(\bar{\theta}) = \frac{(-1)^{n-m}}{2^n(n-m)!}\sqrt{\frac{(n-m)!}{(n+m)!}}\,(1-\sin\theta)^{-m/2}$$
$$(1+\sin\theta)^{-m/2}\frac{\mathrm{d}^n}{\mathrm{d}(\sin\theta)^n}[(1-\sin\bar{\theta})^{n-m}\,(1+\sin\bar{\theta})^{n+m}] \tag{3}$$

where m denotes the order of the harmonic and n the degree, m and n being positive integers. Let a_n^m and b_n^m be spherical harmonic coefficients in the expansion of magnetic potential v. If the magnetic pattern is displaced longitudinally by angle $\bar{\varphi}$ and in latitude by angle $\bar{\theta}$ the coefficients will be modified as

$$a_n^m \rightarrow [a_n^m \cos m\bar{\varphi} - b_n^m \sin m\bar{\varphi}]\, u_n^m(\bar{\theta})$$
$$b_n^m \rightarrow [a_n^m \sin m\bar{\varphi} + b_n^m \cos m\bar{\varphi}]\, u_n^m(\bar{\theta}) \tag{4}$$

If A_n^m and B_n^m be the spherical harmonic coefficients in the spherical harmonic expansion of gravitational potential U, then the correlation coefficient k defined as

$$k = \frac{\sum_{m,n}(a_n^m A_n^m + b_n^m B_n^m)}{[\sum_{m,n}[(a_n^m)^2 + (b_n^m)^2]]^{1/2}\,[\sum_{m,n}[(A_n^m)^2 + (B_n^m)^2]]^{1/2}} \tag{5}$$

will remain unchanged on further displacement of magnetic pattern in latitude. The high degree of correlation observed by Hide and Malin[1] requiring a displacement of the magnetic pattern 160° to the east is not therefore affected by the displacement in latitude. This further supports Hide's suggestion[2] that core motions are probably chiefly zonal.

Earthquake Lightning

IN some parts of the world, earthquakes are often accompanied by ball lightning, stroke lightning and sheet lightning[1]. The only causal connexion that seems possible is that the seismic strains of the earthquake somehow cause an electric field in the air, which in turn produces ball lightning[2] and stroke and sheet lightning. What is the mechanism of this "seismoelectric effect"?

It is suggested by Terada[3] that the streaming potential of subterranean capillary flow of water causes these electric fields. We estimate, however, that the seismic stresses necessary to produce breakdown fields by this mechanism are several orders of magnitude greater than exist during earthquakes. Electrostatic generation by dust, which is probably important in volcano lightning, is not significant in these earthquakes.

We propose that the piezoelectric effect in the Earth's crust causes the electric field.

The only significant piezoelectric constituent of the crust seems to be quartz. The mere presence of quartz is not sufficient; there must be the right kind of long range crystalline order or texture, for example, $m3:m$ or ∞m. The existence and magnitude of just such order are known from piezoelectric prospecting for quartz-bearing ores[4–6]. The range of order relevant to the seismoelectric effect is the wavelength of seismic waves (~ 2 km). Natural geological structures of this size may exhibit effective piezoelectric coefficients of the order of several per cent that of x cut single crystal quartz.

The long range order implied by these measurements is probably the result of the stress history shared by rocks in one tectonic unit[7–9]. At the relevant temperatures the z axes of quartz crystals tend to line up along the principal direction (eigenvector) of greatest stress. In one rock, for example, 50 per cent of the z axes are within 6·4 degrees of the principal stress direction[10]. There are several processes which can then order the x axes of the z ordered quartz grains. Secondary stresses may order the flats of quartz grains by mechanical action, thus ordering the x axes up to sense. An ordering of their senses occurs in the elimination of Dauphiné twinning by a shift in the direction of principal stress[11].

In rock with a mean piezoelectric coefficient several per cent that of x cut single crystal quartz, and with typical seismic stress changes 30–300 bars, an earthquake makes an average electric field of 500–5,000 V cm^{-1}. For distances of the order of half the seismic wavelength, the generated voltage is 5×10^7 to 5×10^8 V, which is comparable with the voltage responsible for lightning in storms. The impedance presented to this generator by a thin stratum of conductive soil or by conduction through the rock itself does not significantly load it at typical seismic frequencies.

For example, the North Idu peninsula earthquake of November 26, 1930, the best documented instance[3,12] of seismoelectricity (over fifteen hundred sightings), occurred in a region with widespread quartz rich lava flows. The geology and petrology of this area have been extensively treated by Kuno[13–15]; near Mt Hakone, the approximate centre of earthquake lightning, most of the lava flows contain between 15 and 30 per cent by weight of free silica, usually in the form of quartz. Some rocks contain up to 43 per cent free quartz. The rocks are usually crystalline and rarely glassy. In addition to these lava flows there are many regions with exposed dikes and plugs which contain large amounts of quartz and which have crystallized very slowly. One particular quartz diorite plug north of Mt Hakone forms a whole mountain, Yagura-dâke, approximately 1 km across. This plug is only a few km north of the active Hakone fault along which there was extensive slippage during the earthquake of November 26, 1930. The whole North Idu region has been undergoing tectonic processes since the late Tertiary[16] with consequent strong regional shearing stresses. Thus we conclude that extensive long range ordering of quartz rich rocks has probably taken place in this region.

These calculations make certain predictions possible. We expect that field measurements will show ground voltage differences in the North Idu region during earthquakes, differences sometimes large enough to cause atmospheric electric discharges. It surprises us that while minute piezomagnetic fields of seismic origin have

been explored[17], no attention seems to have been paid to such gross piezoelectric fields.

There should also be very low frequency electromagnetic radiation from seismoelectric waves ranging from 10 Hz, the approximate upper frequency of seismic waves, to well below 1 Hz, and from transient stress changes at higher frequencies. The seismic waves provide an effective 1 km³ antenna carrying a current of some 1 to 10 A with a spectral maximum near 1·5 Hz, the approximate maximum for seismic waves. The radiation takes place into the atmospheric cavity whose fundamental frequency is approximately 7 Hz. Electromagnetic radiation from 1·5 Hz seismic waves will be of low power ($\ll$1 W) but radiation from higher frequency transients will be much more intense.

There will also be electrical precursors to earthquakes resulting from changes in stress near earthquake foci. There is a tradition in Japan of predicting earthquakes, sometimes with great saving of life, from unusual clear sky lightning[3]. It may be possible to put this kind of prediction on a more systematic basis using more sensitive and quantitative electric measuring instruments than earthquake lightning.

Crack Growth under Creep Conditions

In recent years there has been a growing awareness that the techniques of linear elastic fracture mechanics provide a powerful method for quantifying the behaviour of engineering components containing crack-like defects. In the fast fracture of high strength, low toughness materials[1] and in fatigue crack growth[2], it is now established that data from laboratory tests can be confidently applied to predict the integrity of a structure or crack extension in service using sharp crack stress intensity factors. More recently, a study of fatigue crack initiation from sharp notches in mild steel[3] has shown that the number of cycles to initiate a crack can also be calculated using stress intensity factors. In components which operate at elevated temperatures there is a need to develop methods which describe the growth of crack-like defects in creed conditions. This is particularly relevant to welded joints where defects can be evident after stress relief and assessments are required of fitness for use.

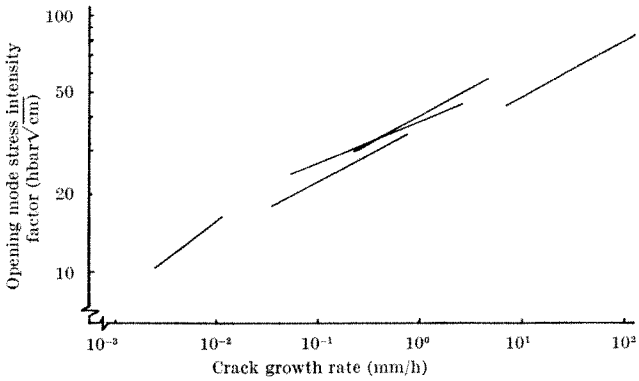

Fig. 1. The relationship between sharp crack stress intensity factor and crack growth rate for 2·25 per cent Cr, 1 per cent Mo steel under creep conditions at 565° C.

The mechanisms of creep fracture in terms of the nucleation and growth of cavities and cracking at grain boundary triple point junctions have been extensively studied[4–7]. Direct studies of crack growth in creep conditions leading to a quantitative description of material behaviour are, however, relatively few[8,9]. This has no doubt been principally because of the lack of a convenient technique for the measurement of crack length at elevated temperature. This difficulty can be overcome by using the electrical resistance method as described by Gilbey and Pearson[10]. The technique has been used in these laboratories during the past three years and has proved reliable; good discrimination has been achieved by the use of high specimen currents, high sensitivity recorders and by careful attention to experimental detail.

Work has been carried out on samples of 2·25 per cent Cr 1 per cent Mo steampipe steel, which had been quenched from 1,350° C to simulate the heat affected zone of a weld. Edge notched rectangular cross-section tensile specimens were tested in air at 565° C using a conventional lever loaded creep machine and the voltage drop across the crack was monitored continuously. The specimen dimensions were: parallel gauge length 75 mm, width 25 mm, thickness 5 mm, and initial notch depth 2·5 mm. Dead loads were applied which produced nominal stresses from 10 to 44 hbar and caused fracture in times up to about 1000 h. Some results are presented in Fig. 1 where each line represents a single test. An equation describing all the tests has the form

$$\dot{a} = \text{constant } K^n$$

where $\dot{a}$ is the crack growth rate, K is the stress intensity factor and where the value of n is about 5·5. This value is similar to the exponent that relates minimum creep rate to stress for materials of this type[11,12]. Correlations of growth rate with nominal applied stress or net section stress produced families of approximately parallel lines. There are obvious objections to applying linear elastic fracture mechanics to a creep situation, but we consider that the present findings represent a useful empirical relationship. Limited tests to verify the generality of the results, by testing at constant stress intensity factor by progressive load reduction with crack growth and by alteration of specimen dimensions, produced crack growth rates in agreement with the equation. The results encourage the view that it may be possible to establish relationships in high temperature crack propagation analogous to these which have already proved so useful in lower temperature applications.

BIOLOGICAL SCIENCES

Subcellular Distribution of Neutral Protease and Peptidases in Rabbit Polymorphonuclear Leucocytes

SEVERAL peptidases which are active around neutral *p*H have been described in polymorphonuclear (PMN) leucocytes. One of these, which we have found concentrated within the lysosomes of rabbit peritoneal exudate PMN cells, hydrolyses histone but not haemoglobin at neutral *p*H[1,2]. Here we compare the subcellular distribution of this enzyme with that of three peptidases active at near-neutral *p*H in rabbit PMN cells. Hydrolysis of their respective substrates seems to be due to separate activities, and this distinction must precede any attempts to ascribe a function to the enzymes in tissue injury[3–6].

The three peptidases whose subcellular distribution is described are (*a*) leucine 2-naphthylamidase (LNA), representative of several amino-acid naphthylamidases previously described in rat peripheral blood PMN cells[3]; (*b*) acetyl-DL-phenylalanine naphthylesterase (APNE) described in viable rabbit peritoneal exudate PMN cells and implicated in the chemotactic process[4] and; (*c*) benzyloxycarbonyl-L-alanine β-nitrophenylesterase (abbreviated as NBA esterase in ref. 5), which is probably identical to the elastinolytic enzyme[6] in human circulating PMN cells.

In all experiments we used rabbit peritoneal exudate PMN obtained by established procedures[7]. Three subcellular fractions were obtained by differential centrifugation[8]: nuclear debris (400*g* for 10 min); these granule (8,200*g* for 15 min) and a postgranule supernatant were treated with 0·1 per cent 'Triton X-100' to release particulate enzymes. All fractions were assayed for protein content[9], β-glucuronidase activity[10] and neutral protease activity, determined as arginine containing sulphosalicylic acid-soluble material released from calf thymus histone[1]. One or more of the peptidases (LNA, APNE, NBA) were assayed in subcellular fractions of different preparations and their subcellular distribution was compared with that of neutral protease and β-glucuronidase, two enzymes present in the azurophile (lysosomal) fractions of rabbit PMN[1,11]. A recovery of β-glucuronidase in the granule fraction of 77·4 ± 9·8 per cent in five experiments indicated the reproducibility of the fractionation procedure. Because not all of the fractions were assayed for LNA, APNE and NBA, results for each enzyme are given for representative experiments.

LNA activity was measured by diazotization of naphthylamine released with *o*-aminoazotoluene diazonium salt (0–5 mg/ml.) after incubation of equal volumes of subcellular fractions and substrate (0·5 mg/ml. in 0·2 M Tris-maleate buffer *p*H 7·2). Colour development was complete after 10 min when absorbance was measured at 525 nm. Table 1 shows that LNA activity was predominantly in the postgranule supernatant. Further fractionation of the postgranule supernatant by centrifugation at 105,000*g* for 2 h showed that the pellet had a specific activity five times greater than the supernatant. Only a small proportion of LNA activity was present in the granule fraction in which β-glucuronidase and neutral protease were concentrated. The different subcellular distribution of neutral protease and LNA suggests that these are different enzymes. As pointed out by Barrett[12], however, L-leucine naphthylamide may be hydrolysed by several enzymes of varying properties. Indeed, lysosomal and microsomal amino-acid naphthylamidases, LNA among them, are clearly distinguishable on the basis of their activation and inhibition by various reagents[13]. The possibility has been raised that cathepsin B displays LNA activity at neutral *p*H[14,15]. This enzyme, however, was absent from rabbit PMN when benzoyl arginine amide hydrochloride was used as a substrate[16]. Moreover, it was clear that cathepsin B was not responsible for the LNA activity in human rheumatoid synovium[17]. This has been confirmed by the chromatographic separation of LNA from cathepsins B and B′; the latter enzymes were shown to be devoid of LNA-like activity[18]. Only further detailed investigation will reveal whether more than one enzyme is responsible for the LNA activity shown in Table 1.

Table 1. PERCENTAGE DISTRIBUTION OF PROTEIN, NEUTRAL PROTEASE (HISTONE), β-GLUCURONIDASE AND LEUCINE-2-NAPHTHYLAMIDASE IN PMN SUBCELLULAR FRACTIONS

	Nuclear debris	Granule	Postgranule supernatant
Protein	4·0	30·5	65·5
Neutral protease	1·0	99·0	0
β-Glucuronidase	3·5	82·0	14·5
Leucine-2-naphthylamidase	5·0	20·9	74·1

Combined recovered specific activities were: neutral protease, 5·28 μg arginine/mg protein/h; β-glucuronidase, 90·0 μg phenolphthalein/mg protein/h; and leucine-2-naphthylamidase, 6·3 μg naphthylamine/mg protein/h.

Hydrolysis of acetyl-DL-phenylalanine naphthylester was measured in the same manner as described for leucine 2-naphthylamide. The substrate was dissolved in N,N-dimethylformamide and acetone as detailed by Becker and Ward[4]. Table 2 shows that APNE was almost completely absent from the granule fraction; more than 80 per cent of the activity was detected in the postgranule supernatant. Moreover, in an experiment where this fraction was centrifuged at 100,000*g* for 2 h, esterase activity was confined almost entirely to the pellet, the specific activity of which was seven times greater than that of the combined fractions. This enzyme was first found in living PMN cells[4] when it was separated into three components, two of which are irreversibly inhibited by different phosphonate concentrations. One of the phosphonate sensitive enzymes was identified as the esterase of chemotaxis on the basis of its profile of inhibition by a variety of phosphonate compounds. Appearance of esterase activity in microsomal fractions could represent the association of the enzyme with small granules or with relatively intact fragments of the cell membrane itself which sedimented at 100,000*g*. Until it has been located correctly, its role in chemotaxis cannot be fully evaluated.

NBA has been described as a substrate for pancreatic elastase[19] and was subsequently shown to be hydrolysed by crude extracts and semipurified preparations of human PMN lysosomes[6]. These preparations gave similar increases in specific activities for hydrolysis of orcein-elastin and NBA suggesting their identity. NBA esterase activity was also found in rabbit PMN cells (Table 3). Enzyme activity was assayed as previously described[5]

Table 2. PERCENTAGE DISTRIBUTION OF PROTEIN, NEUTRAL PROTEASE (HISTONE), β-GLUCURONIDASE AND ACETYL-DL-PHENYLALANINE NAPHTHYLESTERASE IN PMN SUBCELLULAR FRACTIONS

	Nuclear debris	Granule	Postgranule supernatant
Protein	12·2	29·3	58·5
Neutral protease	0	100	0
β-Glucuronidase	18·1	70·0	11·9
Acetyl-DL-phenylalanine β-naphthylesterase	15·0	4·0	81·0

Combined recovered specific activities were: neutral protease, 2·10 μg arginine/mg protein/h; β-glucuronidase, 164·5 μg phenolphthalein/mg protein/h; and acetyl-DL-phenylalanine β-naphthylesterase, 63·6 μg naphthylamine/mg protein/h.

Table 3. PERCENTAGE DISTRIBUTION OF PROTEIN, NEUTRAL PROTEASE (HISTONE), β-GLUCURONIDASE AND NBA ESTERASE IN PMN SUBCELLULAR FRACTIONS

	Nuclear debris	Granule	Postgranule supernatant
Protein	6·7	30·5	62·8
Neutral protease	1·7	93·9	4·4
β-Glucuronidase	5·7	76·3	18·0
NBA esterase	6·7	59·0	34·3

Combined recovered specific activities were: neutral protease, 6·0 μg arginine/mg protein/h; β-glucuronidase, 110·2 μg phenolphthalein/mg protein/h; and NBA esterase, $\Delta A_{400} = 0{\cdot}462$/mg protein/min.

except that the *p*H was 7·2 and *p*-nitrophenol release was measured at 400 nm. The enzyme (Table 3) was found chiefly in the granule fraction, as was human PMN orcein-elastase activity[6]. The subcellular distribution of NBA esterase activity in human PMN cells has not been reported. NBA esterase differs from neutral protease in that a far higher percentage of its total activity is found in the postgranule supernatant. Other differences observed between the two enzymes are: (*a*) NBA esterase activity of the granule fraction is only partially inhibited (52 per cent) by postgranule supernatant in contrast to the complete inhibition by this fraction of neutral protease[1]; (*b*) total recovery of NBA esterase activity from subcellular fractions approximates that found in whole cells whereas neutral protease recovery amounts to from seven to twenty times that found in whole cells. This finding is explained by the presence of a potent inhibitor of neutral protease in postgranule supernatant fractions[1]. These data support the possibility that NBA esterase and neutral protease are different enzymes, although, because NBA is a more sensitive substrate than histone, smaller enzyme protein concentrations had to be used in assays with NBA as substrate.

However valid the use may be for leucine-2-naphthylamide as a marker substrate for lysosomal enzymes in some cell types[20], our data suggest that the bulk of this activity in PMN is not associated with lysosomes in conditions which permit the localization in these granules of neutral protease and β-glucuronidase. Because the subcellular distribution of hydrolytic activity was distinct for each substrate it would appear reasonable that there exist in PMN at least four separate peptidases active at near-neutral *p*H. The isolation of these enzymes by various procedures will be the subject of a future report.

This work was supported by grants from the US Public Health Service and the National Cystic Fibrosis Research Foundation. P. D. is an SRC/NATO postdoctoral fellow.

Vitamin A Inhibition of Cortisol Induction of HeLa Alkaline Phosphatase

HELA 65 [1], an aneuploid clone derived from a transformed human cervical carcinoma, has a low level of alkaline phosphatase that is elevated 10 to 15-fold by cultivating the cells with cortisol[2–4]. This enzyme "induction" occurs through synthesis of new alkaline phosphatase messenger RNA[3] at a point in the cell cycle just after initiation of DNA synthesis[5], but the result of these alterations is a more active (efficient) enzyme population, not an increase in the steady state level of control enzyme[4]. These findings have been interpreted as cortisol-effected alterations in the translation of recently synthesized alkaline phosphatase messenger RNA[4,5]. The present study shows that vitamin A inhibits this cortisol mediated increase in enzyme activity, suggesting a membrane component as a mutual cellular target for retinol and cortisol.

HeLa 65 cells were grown in Eagle's minimal essential medium (MEM) supplemented with 10 per cent calf serum, 50 units penicillin and 50 μg/ml. each of streptomycin and kanamycin. Kinetic studies of cortisol mediated induction of this phosphatase have shown 72 h as an optimum time for maximum acute effect on the enzyme[3]. Fig. 1 shows a dose response curve of (all-*trans*)-retinol inhibition of cortisol (3 μM) "induction" of alkaline phosphatase after 72 h of cell growth with these agents. The points are an average of triplicate experiments with duplicate biological samples, and standard deviation was less than 10 per cent. The minimum point on the dose curve is 0·2 μg/ml. retinol, for the growth medium contained 10 per cent calf serum, and the serum used for most of these studies contained 2·0 ± 0·3 μg/ml. saponifiable retinol (assay performed by N. Chiba and B. Warriner). Several other compounds of the vitamin A class had this effect, but little or no inhibition was produced by a variety of other fat soluble vitamins (Table 1).

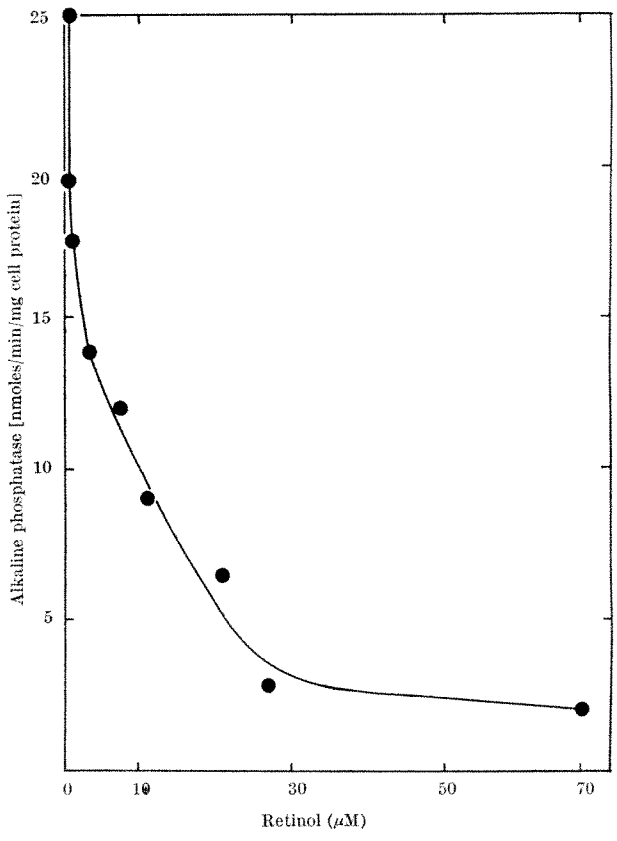

Fig. 1.

Increasing concentrations of cortisol could be counter-effected by increased concentrations of retinol up to about 100 μM, which killed most of the cells. Another HeLa cell clone which has high constitutive levels of the phosphatase (HeLa 71) was not affected by retinol or its derivatives, either in control or hydrocortisone regulated states (continuous growth and subculturing with cortisol). The alkaline phosphatase level of HeLa 65 in the hydrocortisone regulated state could also be reduced to control levels by addition of retinol to the growth medium.

The concentration of retinol in the medium is plotted in Fig. 1, and because HeLa 65 cells concentrate retinol, cellular concentrations are shown in Table 2. In another study[5], radioactive hydrocortisone has been shown not to be concentrated by HeLa 65 cells. Thus the 3 μM cortisol medium concentration amounts to a 3 μM cell concentration, but a cellular retinol concentration resulting in 74 per cent inhibition (10 μM medium concentration) is estimated at about 1,400 μM (140-fold concentration). If each effector interacts reversible at a single type of cellular site, cortisol is about 460 times as effective as retinol (1,400/3). Because HeLa alkaline phosphatase is predominantly a membrane bound enzyme[6], a membrane cellular site is suggested.

Table 1. INHIBITION OF CORTISOL BY FAT-SOLUBLE VITAMINS

Compound	Concentration (μM)	Alkaline phosphatase† (per cent of cortisol treated)
Retinol	10	36

Table 2. CELLULAR CONCENTRATIONS OF RETINOL

Medium	Retinol concentration (μM) Cells*	Fold increase
17	2,400	140
70	8,900	130
175	11,600	67

* Assayed spectrophotometrically by a difference in absorbance at 325 nm between control and retinol treated cells using a 0·5 per cent sodium deoxycholate cell lysate. This value is based on a volume of cell water for HeLa 65 of 3·5±0·4 μl./10^6 cells.

Several studies have reported vitamin A induction of alkaline phosphatase in rat skin fibroblast cells[7,8]. One of these studies[7] showed that the acute elevation of the phosphatase by topical application of vitamin A to wounded rats could be counteracted somewhat by simultaneous topical application of hydrocortisone. This seems to be a sort of mirror image of the HeLa system described above, and suggests some generalized membrane system which interacts with both cell effectors. Preliminary experiments in these laboratories show no effect of either cortisol or vitamin A on human skin fibroblasts cultivated *in vitro*. Cortisol has been shown to antagonize partially the action of vitamin A on both embryonic fowl skin[9] and embryonic cartilage and bone in culture. Again membrane systems have been implicated as site(s) of action.

We thank Dr B. Connor Johnson for helpful discussion and Barbara Warriner for technical assistance.

Biological Activity of a Polar Metabolite of Vitamin D_3

NEW interest is being shown in the nature of the metabolites of vitamin D, particularly those found in the target tissues, and in the part they play in controlling Ca^{2+} metabolism[1-4]. The first to be identified was 25-hydroxycholecalciferol (25-HCC) which is 1·4 times more potent than cholecalciferol itself[2] and which we have shown to be converted to a more polar metabolite, not yet fully characterized. Experiments with [1-^{3}H,4-^{14}C] cholecalciferol indicated that all the ^{3}H is lost during the formation of this metabolite. This suggests that there is an oxygen function at C-1 as well as at C-3 and C-25 (refs 3 and 4). Contrary to the original reports[5], it is this metabolite (designated compound P) and not 25-HCC that is found in the intestinal nuclei of chicks. The intestine is the richest source of compound P, although it is also found in other tissues, particularly kidney, bone, liver and muscle[3,4].

In the intestine, compound P has never been found at concentrations above 1 ng/g of tissue, although it is the predominant form of the vitamin found in the intestine after a physiological dose of cholecalciferol. Because of the scarcity of material, classical bioassays based on the changes in bone calcium effected by vitamin D could not be done. But because it was of paramount importance to establish whether or not this substance has biological activity we used a modification of the assay procedure of Norman[6], which involves another function of vitamin D, namely the increase in the intestinal absorption of Ca^{2+}, and which requires very small amounts of the vitamin.

Recently Myrtle, Haussler and Norman[7] have reported that their compound IVb, isolated from chick intestine and which has similar properties to compound P, has biological activity although they did not estimate its relative potency. We have attempted to establish the relative potency of compound P.

To prepare sufficient metabolite for the assay, 440 rachitic chicks were dosed with 0·5 μg of [1,2-$^3H_2$,4-^{14}C] cholecalciferol (51 mCi/mmole). The birds were killed 24 h later and the intestines were removed and saponified. The unsaponifiable matter was chromatographed on silicic acid columns to remove cholesterol and other relatively nonpolar material. The fraction containing compound P was further purified by thin layer chromatography with ethyl acetate/heptane (1 : 1) as the developing solvent. In this way 2 μg of [1,2-$^3H_2$,4-^{13}C] compound P in 14 mg of lipid was obtained. The ^{14}C radioactivity was used for measurement of the amount of compound P.

In the bioassay procedure the standard and test substance was administered intracardially to groups of five rachitic chicks. After 24 h a solution of 1 μCi of ^{45}Ca (0·5 μCi/mg) in 0·25 ml. of water was given orally and the blood was collected 1 h later. The ^{40}Ca content of the serum was measured by the procedure of Wales[8] and the ^{45}Ca content was assayed in 0·1 ml. of serum using a Packard liquid scintillation spectrometer.

A preliminary experiment showed that the response of rachitic chicks to 125 ng of compound P, indicated by the serum ^{45}Ca content, was 50 per cent greater than that

obtained with 125 ng (5 IU) of cholecalciferol. Indeed the response was almost equivalent to that obtained with 1500 ng (60 IU) of cholecalciferol. After 24 h, however, the serum ^{40}Ca concentration, (7·5 mg per cent) was unaffected by 125 ng of both compound P and vitamin D, although 1,500 ng of the vitamin induced a concentration of 10·4 mg per cent which is close to the normal level.

The results of a second experiment designed to measure the relative potency of compound P are shown in Table 1. Regression lines were fitted to the data expressing the relationship between $\log_{10}$ of the dose and the response obtained. They fit a common slope. Compound P was 2·9 times as potent as the standard, while 25-HCC was no more potent than cholecalciferol. The fiducial limits were calculated in the usual way to give 95 per cent limits of 1·5–5·4 for compound P and 0·43–1·68 for 25-HCC. Also shown in Table 1 are the serum ^{40}Ca concentrations. The 250 ng (10 IU) and 500 ng (20 IU) of vitamin D_3 and 250 ng of 25-HCC restored normal concentrations but this effect lasted for only 7–14 days. In contrast, the 125 ng (5 IU) of compound P had no effect, again showing that it is no more effective in raising blood calcium levels than vitamin D itself. The blood calcium increasing effect, which one can interpret as the mobilization of bone calcium, might be absent because a single dose of the active compound P has only a short lived effect. The action of a dose of cholecalciferol or 25-HCC, on the other hand, could be more lasting, because these substances generate compound P continuously. This is in keeping with the working hypothesis that vitamin D, in the form of the active compound P, has a direct effect on bone formation, in that it is necessary for the efficient accretion of calcium. It will be of interest, therefore, to test the ability of compound P to maintain bone ash values. Alternatively, it is possible that the polar metabolite of vitamin D does not have the blood calcium increasing action of vitamin D, and that this effect is mediated by 25-HCC as suggested by Trummel *et al.*[9].

Table 1. THE RELATIVE POTENCY OF VITAMIN D_3, 25-HYDROXYCHOLECALCIFEROL AND COMPOUND P ON ^{45}Ca-INTESTINAL TRANSFER AND THEIR EFFECT ON SERUM CALCIUM OF RACHITIC CHICKS

Dose level ng	Vitamin D_3 serum levels ^{45}Ca	Vitamin D_3 serum levels ^{40}Ca	25-HCC serum levels ^{45}Ca	25-HCC serum levels ^{40}Ca	Compound P serum levels ^{45}Ca	Compound P serum levels ^{40}Ca
25	—	—	—	—	2,800	—
62·5	2,200	—	2,600	—	3,100	—
125	2,500	—	3,000	—	4,500	10·2
250	3,700	12·7	4,400	12·3		
500	4,900	12·1				
Relative biological potency (per cent)	100	—	115	—	290	—
95 per cent fiducial limits	—		43 < R.P. < 168		150 < R.P. < 540	

The results are the means of five determinations. Serum ^{45}Ca levels are expressed as c.p.m./ml., the value for the rachitic control group being 1,900 c.p.m./ml. serum. The serum ^{40}Ca levels are expressed as mg per cent with the value for the rachitic control group being 9·6 mg per cent.

In the first experiment the birds dosed with [1,2-$^3H_2$, 4-^{14}C] compound P were killed at 24 h and the ^{14}C and ^3H contents of the tissues were examined. Radioactivity was detected only in the intestinal mucosa, and it amounted to as little as 1·2 per cent of the dose. In subsequent experiments a double labelled compound P (17 ng, 1 nm Ci) was infused into rachitic chicks in 2 ml. Tris buffer (*p*H 7·4) containing 100 mg of bovine plasma albumin. At the end of the 10 h infusion period the radioactivity was distributed over a wide range of tissues that included intestine, liver, kidney, bones and muscles; only 4 per cent of the dose was present both in the intestine and the liver. These infusion experiments, in which we have tried to simulate the apparent circulating concentration, suggest that the injected compound P, derived from the intestine, seems to be rapidly metabolized.

Consideration of the turnover time of compound P and the purity of this particular preparation may well show that the compound is in fact even more potent. The three-fold increase in potency relative to cholecalciferol found in these experiments means that compound P is the most potent substance so far known to have vitamin D activity. It should be emphasized that in these experiments we have tested the biological activity of the polar metabolite of vitamin D formed by reactions involving the metabolic loss of hydrogen from C-1. This compound is distinct from the other compounds of similar polarity which have not lost this hydrogen.

Determination of the mode of action of the functionally active form of vitamin D and its effect on bone metabolism will require further study. 25-Hydroxycholecalciferol, although slightly more potent than cholecalciferol, does not reach a high concentration in the intestine and is not localized in the intestinal cell nuclei[4]. On the other hand, compound P, during the same period, is accumulated in the intestine and is specifically localized in the nuclei[4]. It is at least two and a half times as potent as 25-hydroxycholecalciferol.

We thank Mr D. E. Walters of the Statistics Group, Agricultural Research Council, Cambridge, for the statistical calculations, and Dr D. R. Fraser for help in the infusion experiment.

Unique Biosynthesis by Kidney of a Biologically Active Vitamin D Metabolite

BEFORE the molecule of vitamin D acts in the control of calcium metabolism it is converted to a functional form in at least two metabolic steps. The first, a side chain hydroxylation at carbon 25, was shown by the elegant experiments of DeLuca and his co-workers[1–4]. This metabolite is synthesized in the liver from vitamin D[5,6] and is the major form of the circulating vitamin in blood plasma, not only of experimental rats[1] and chickens[7], but also of man[8]. A second more polar metabolite, localized in intestinal cell nuclei[7,9] and having at least three times the biological activity of an equivalent amount of cholecalciferol[10,11], is derived from 25-hydroxycholecalciferol (25-HCC)[12]. When it is obtained from chickens that have been given [4-^{14}C,1-^3H] cholecalciferol, there is a loss of tritium from carbon 1 (refs. 7 and 12). The tritium deficiency and the greater polarity are compatible with oxygen insertion at carbon 1 of 25-HCC.

The site of synthesis of this substance was not obvious. Although the small intestine mucosal cells contain the highest quantities of the tritium deficient metabolite (up to 1 ng/g), it was found in most tissues, with the lowest concentration in blood[12]. The time course of its

formation gave some indication that 25-HCC was converted to the more polar form in the intestinal mucosa and indeed a recent article from the Wisconsin workers suggests this[13].

Attempts have been made in this laboratory to find the anatomical site of the enzyme and to study the mechanism of tritium removal from [4-^{14}C,1-^{3}H] 25-HCC. Conditions for *in vitro* experiments were based on the possible requirements of oxygen, NADPH and Mg^{2+} as in the hydroxylation of steroids by mixed function oxidases[14]. Homogenates, everted sacs, isolated cells and slices of small intestine from vitamin D deficient chickens were incubated with [4-^{14}C,1-^{3}H] 25-HCC in fourteen experiments; all failed to produce any trace of the tritium deficient metabolite. Incubations of 25-HCC with liver, adrenal, parathyroid, thyroid, ultimobranchial body, thymus, rachitic epiphysis, erythrocytes and blood plasma gave similar negative results. It was observed also that surgical removal from the rachitic chicken of the gastrointestinal tract, pancreas, spleen, thyroids, parathyroids, ultimobranchial bodies, adrenals and thymus did not prevent the formation of the metabolite *in vivo*. Kidney, a seemingly unlikely organ, was the tissue which in *in vitro* preparations eventually produced a reduction in the total $^{3}H : ^{14}C$ specific radioactivity ratio with [4-^{14}C, 1-^{3}H] 25-HCC. Chromatography of the lipid extract from such preparations showed that this ratio was reduced by the formation of a polar, tritium deficient metabolite, chromatographically identical to that found *in vivo* (Fig. 1). As kidney was the only tissue to convert 25-HCC *in vitro* in this way, the possibility of its unique role in vitamin D metabolism was investigated in bilaterally nephrectomized rachitic rats. These were each given 125 ng [4-^{14}C, 1-^{3}H] cholecalciferol in 0·1 ml. propylene glycol by intracardial injection immediately after surgery. Mucosa of the small intestine and blood plasma were collected 24 h later and the lipid extracts were chromatographed on silica gel G thin layers. The proportion of the metabolites is shown in Table 1. The nephrectomized rats did not produce any tritium deficient metabolite in contrast to intact controls which in mucosa and plasma contained about 30 per cent and 7 per cent respectively of total ^{14}C as this substance. Nephrectomy did not impair the synthesis of 25-HCC. These results indicate that the kidney is the only site of synthesis of a vitamin D metabolite, postulated to be necessary for vitamin D function.

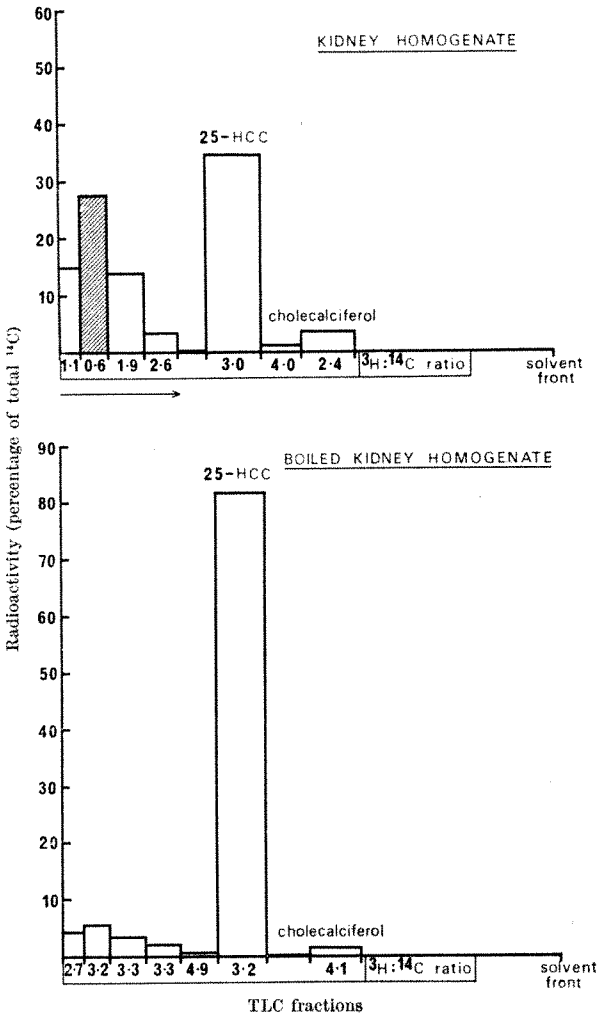

Fig. 1. Thin layer radiochromatogram of $CHCl_3$-methanol extracts from incubation of [4-^{14}C,1-^{3}H] 25-HCC with vitamin D deficient chick kidney homogenate. Silica gel G thin layers were developed with ethyl acetate–heptane (1 : 1) to a 17 cm solvent front. $^{3}H : ^{14}C$ specific radioactivity ratios are given for each fraction. The shaded peak represents the ^{14}C of the tritium deficient metabolite.

Table 1. PERCENTAGE DISTRIBUTION OF VITAMIN D AND ITS METABOLITES IN RACHITIC RATS *in vivo* 24 H AFTER INTRACARDIAL INJECTION OF 125 ng [4-^{14}C,1-^{3}H] CHOLECALCIFEROL

† Radioactivity was too low to calculate reliable ratios.

The mechanism of the metabolic removal of tritium was studied further *in vitro* in kidney from rachitic chicken. Homogenates (12 per cent) of kidney in 0·32 M sucrose, 0·05 M Tris buffer (*p*H 7·4) were incubated in 25 ml. stoppered tubes which contained 2·8 μmoles Mg^{2+}, 30 μmoles nicotinamide, 0·6 μmoles NADP, 6 μmoles glucose-6-phosphate, 0·6 units of glucose-6-phosphate dehydrogenase and 15 μmoles L-malate together with 10–20 mg kidney protein, and 17 ng [4-^{14}C,1-^{3}H] 25-HCC were added in 1 drop of ethanol. The total volume was 1·5 ml. The tubes were gassed with oxygen for 1 min and incubated with continuous gentle agitation at 37° C. The rate of synthesis of the tritium deficient metabolite was linear up to 1 h and had ceased by 2 h. Lipid was extracted with 10 ml. $CHCl_3$-methanol (2 : 1), and the $CHCl_3$ phase, which separated after adding 2 ml. water, was removed. The aqueous methanol residue was further extracted with 10 ml. $CHCl_3$. Recovery of ^{14}C radioactivity in the combined $CHCl_3$ extracts was 85–95 per cent. In boiled enzyme controls recovery was close to 100 per cent. Distribution of enzyme activity in subcellular fractions prepared by differential centrifugation revealed that most of the activity was present in the 700*g* nuclei-debris pellet (Table 2). The major component of this pellet was observed by phase contrast and electron microscopy to be mitochondria which when separated from nuclei, brush borders and erythrocytes by centrifugation on a sucrose gradient contained the enzyme activity. For enzyme induced loss of tritium to occur there was an absolute requirement for molecular oxygen. The heavy mitochondria had little of this activity in the absence of Mg^{2+} or malate, or in the presence of carbon monoxide. These properties are rather similar to those of steroid 11β-hydroxylase found in adrenal cortex heavy mitochondria[15] which requires oxygen, Mg^{2+} (ref. 16) and malate (ref. 17) (the latter being a generator of NADPH via intramitochondrial malic enzyme[18]) and which is inhibited by binding of CO to mitochondrial cytochrome P-450 (ref. 19). Such similarity implies again that the tritium is lost from [4-^{14}C,1-^{3}H]

25-HCC by oxygenation of carbon 1. The fate of the lost tritium was discovered to be in the formation of tritiated water, collected from the total incubation mixture by lyophilization. Recovery of tritium in water exactly matched the loss observed in the lipid extract and in fact proved to be a sensitive assay of the enzyme activity.

What now seems to be the functional intermediary metabolism of vitamin D is illustrated in Fig. 2. The formation of 25-HCC seems to be relatively independent of the supply of environmentally derived vitamin D. Its concentration in plasma of pigs rises as large doses of dietary vitamin are provided[2] and it probably constitutes the circulating reserve of vitamin D activity[13]. On the other hand the synthesis of the kidney metabolite cannot be increased by further administration of vitamin D or 25-HCC (ref. 12). Indeed the administration of 0·5 μg [4-^{14}C,1-^{3}H] cholecalciferol to chickens given 3–5 μg unlabelled cholecalciferol per week for 5 weeks produces very little tritium deficient metabolite and the *in vitro* kidney enzyme activity of such birds was 0–25 per cent of that of vitamin D deficient chickens. We therefore suggest that there is some control over the synthesis of the metabolite by kidney which allows only sufficient quantities for target organ requirements.

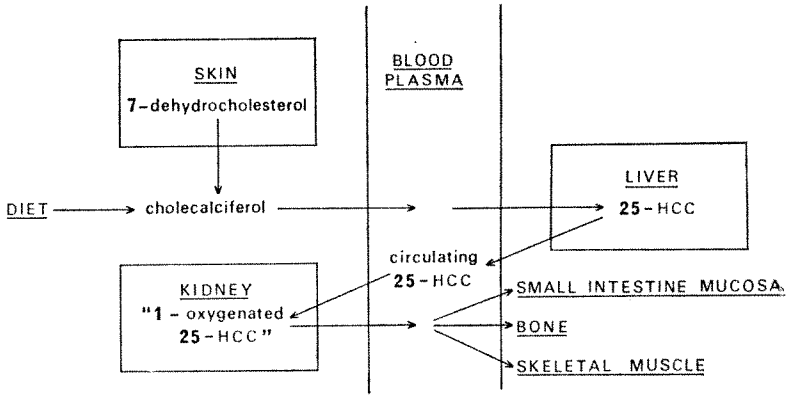

Fig. 2. Functional intermediary metabolism of vitamin D.

Table 2. SUBCELLULAR DISTRIBUTION OF ^{3}H-REMOVING ENZYME ACTIVITY IN HOMOGENATES OF VITAMIN D DEFICIENT CHICK KIDNEY INCUBATED WITH [4-^{14}C,1-^{3}H]25-HCC

	Percentage conversion of 25-HCC to ^{3}H-deficient metabolite	Protein/assay (mg)
(*A*) Subcellular fraction		
Whole homogenate	25·4	19·9
700*g* × 10 min pellet	26·0	18·8
10,000*g* × 10 min pellet	5·6	10·7
100,000*g* × 60 min pellet	0·0	14·9
100,000*g* × 60 min supernatant	0·0	10·0
(*B*) Fractionation of 700*g* pellet		
Whole homogenate	30·8	18·5
700*g* × 10 min pellet	21·2	9·2
Sucrose gradient fractions		
Heavy mitochondria	16·9	16·1
Nuclei	1·3	3·4

The findings reported here could be relevant to the understanding of the pathogenesis of some diseases of calcium metabolism. For instance in chronic renal failure of man there is a variable resistance to the action of vitamin D (refs 20, 21), and an osteodystrophy develops resembling the osteomalacia of vitamin D deficiency[22]. Although previous attempts to identify changes in vitamin D metabolism in renal insufficiency have revealed very little[23,24], the synthesis of the polar biologically active metabolite was not examined and the possibility exists that in renal disease its production from 25-HCC is impaired or abolished. Similarly in familial vitamin D resistant rickets the genetic defect may result in the absence of the kidney enzyme described here. Finally, failure of the kidney vitamin D metabolism to supply sufficient metabolite for intestine and bone to maintain blood calcium levels could explain uncompensated hypocalcaemia such as is seen in dairy cows with parturient paresis.

We thank Dr D. E. M. Lawson for the supply of [4-^{14}C, 1-^{3}H] 25-HCC and Dr D. C. Barker for electron microscopic examination of subcellular fractions.

Inhibition of Bohr Effect after Removal of C-Terminal Histidines from Haemoglobin β-Chains

THE alkaline Bohr effect is the uptake of protons at a *p*H greater than 6 when oxygen is removed from haemoglobin[1]. In horse haemoglobin the α-amino groups of the α-chain contribute about one-quarter of the alkaline Bohr effect[2]. Recently Perutz *et al.*[3] proposed that histidine 146β contributes about half the alkaline Bohr effect. Their evidence was based on the interpretation of a difference Fourier map of deoxyhaemoglobin after reaction with N-ethylmaleimide[4]. This haemoglobin has lost half its alkaline Bohr effect. We have prepared des-(His 146β) human haemoglobin: it exhibits haem-haem interaction and lacks half the alkaline Bohr effect, and thus fully confirms the ideas of Perutz *et al.*[3].

Carbonmonoxy-β-chains (after removal of *p*-mercuribenzoate[5]) were digested with chromatographically purified carboxypeptidase B[6] in 0·2 M barbitone buffer

(*p*H 8·2) at 37° C for 4 h at an enzyme to substrate ratio of 1 : 1,000. This removes about 60 per cent of histidine 146β, and an equal 10 per cent of both tyrosine 145β and lysine 144β. After digestion the enzyme was removed by passage through a DEAE-cellulose column equilibrated with 0·05 M sodium phosphate buffer (*p*H 6·9). The digested β-chains were then chromatographed on a CM-cellulose column using a salt gradient of 0·01–0·1 M sodium acetate (*p*H 6·0). Three peaks were isolated; the first (presumed to be β-chains from which residues 146, 145 and 144 had been removed) was discarded. A stoichiometric amount of α-chains was added to the second and third peaks and they were digested with carboxypeptidase A[7] to identify them. The results in Table 1 show that peak 2 contains des-(His 146β) β-chains and peak 3 is undigested β-chain. Complete release of arginine 141α after digestion of both haemoglobins with carboxypeptidase B shows that all of this enzyme had been removed after the original digestion of the β-chains.

Table 1. PROPERTIES OF PRODUCTS OF DIGESTION

	Residue	Peak 2 + α-chains	Peak 3 + α-chains	Human haemoglobin
CPA digestion (moles residue/$\alpha\beta$ dimer)	Tyr 145β	0·90	0·90	0·90
	His 146β	0·004	0·95	0·96
CPB digestion (moles residue/$\alpha\beta$ dimer)	Arg 141α	0·93	0·94	0·86
Hill's constant n		2·5	2·8	2·8
Oxygen affinity ($p_{\frac{1}{2}}$), mm Hg, 0·2 M sodium phosphate (*p*H 7·0, 25° C)		2·5	9·5	9·2
Bohr effect $\Delta \log p_{\frac{1}{2}}/p$H		0·23	0·48	0·51

The results of oxygen dissociation curves in 0·2 M phosphate buffer are shown in Table 1. The control haemoglobin (that is, the undigested β-chains recombined with α-chains) has properties identical with normal human haemoglobin. Des-(His 146β)-haemoglobin has a slightly lower Hill's constant n, indicating a slight loss of haem-haem interaction; the alkaline Bohr effect as measured in 0·2 M phosphate buffers between *p*H 7·0 and 7·8 has been halved. The Bohr effect was then measured directly from titration curves and the results are shown in Fig. 1. The control haemoglobin has a normal Bohr effect, while the des-(His 146β) haemoglobin has a halved alkaline Bohr effect. The acid Bohr effect (the release of protons at a *p*H below 6 when oxygen is removed from haemoglobin) in des-(His 146β) human haemoglobin seems to be largely intact. Thus the major part of the acid Bohr effect is not linked to this part of the alkaline Bohr effect. Indeed, the shape of the curve of the dependence of the Bohr effect of des-(His 146β) haemoglobin on *p*H is that calculated from the theoretical model of Wyman[9] assuming that half the alkaline Bohr groups have been removed, but that the acid Bohr groups are intact. It seems that part of the acid Bohr effect is linked to that part of the alkaline Bohr effect coming from the α-chains, for when this is specifically inhibited in des-(Arg 141α)-haemoglobin (which has an n of 1·8), a part of the acid Bohr effect is also inhibited[10]. The rest of the acid Bohr effect is not linked to the alkaline Bohr effect, for des-(His 146β,Arg 141α)-haemoglobin, which has no alkaline Bohr effect nor haem-haem interaction still possesses a significant acid Bohr effect[10].

Glucagon stimulates Brunner's Gland Secretion

GLUCAGON and secretin, chemical homologues having 14 similar amino-acids in identical positions[1], induce choleresis[2], stimulate insulin release[3] and inhibit gastric secretion[4]. Glucagon, however, inhibits, while secretin stimulates, pancreatic fluid and electrolyte secretion[5]. Because three different preparations of secretin—synthetic porcine (Squibb), pure natural porcine (Jorpes and Mutt) and impure porcine (Boots)—stimulate Brunner's gland secretion[6–8], we investigated whether glucagon would affect Brunner's gland secretion in dogs.

In fifteen anaesthetized dogs (18–23 kg) of both sexes, a vagally denervated area of proximal duodenum with an intact blood supply was mounted in a lucite chamber. The main pancreatic and common bile ducts were ligated and divided. The orifice of the accessory pancreatic duct was maintained outside the internal diameter of the chamber. A stable level of anaesthesia was achieved and constant temperature (38° C–39° C) was maintained in both the animal and the duodenal explant. Brunner's gland secretion was studied in the resting state and in response to: (*a*) graded doses of glucagon (Eli Lilly and Co., Indianapolis, Indiana) 0·5 to 25 μg/kg as a single intravenous injection, (*b*) glucagon by continuous infusion (0·50–0·20 μg/kg/min), (*c*) a single dose of glucagon (10 μg/kg) superimposed on a continuous infusion of glucagon (1 μg/min). The order of doses was randomized. Fifteen minute collections of secretion were analysed individually for volume, HCO_3^-, Na^+, Cl^-, K^+ and protein concentration. Blood sugar levels were determined before and after glucagon injection.

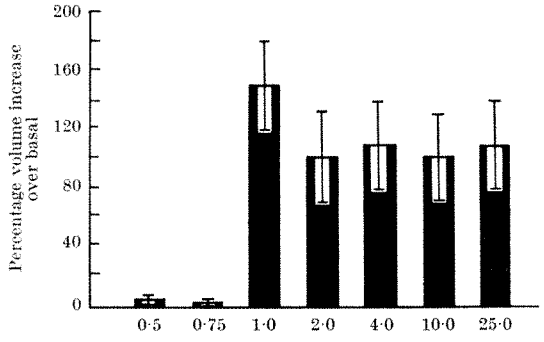

Fig. 1. Effects of graded doses of glucagon by single injection on volume response of Brunner's gland area.

Mean basal Brunner's gland secretion was $0{\cdot}85 \pm 0{\cdot}26$ (s.d.) ml./15 min. Glucagon produced a sharp increase in volume output. The threshold dose for stimulation was 1 μg/kg. Glucagon (1–25 μg/kg) resulted in an increase in secretion of 100 per cent–160 per cent (Fig. 1). The peak response was attained with 1 μg/kg; higher doses did not produce any greater increase in volume. Continuous glucagon infusion alone increased volume output by 80 per cent (Fig. 2); the peak effect was lower than that achieved by a single dose. When a single injection (10 μg/kg) was superimposed on a continuous glucagon infusion, however, further stimulation occurred (40 per cent increase). The peak effect equalled the maximum response to glucagon injection alone. Glucagon did not alter the electrolyte or protein concentration of the secretion but increased their output (Table 1). Blood sugar levels were unaltered by the doses of glucagon used in this study.

Table 1. EFFECTS OF GRADED DOSES OF GLUCAGON ON ELECTROLYTE AND PROTEIN CONCENTRATION OF BRUNNER'S GLAND AREA

Glucagon injection (μg/kg)	Electrolyte concentration (mequiv/l.) Na^+	K^+	Cl^-	HCO_3	Total protein concentration (mg/ml.)
Basal	$146 \pm 1{\cdot}1$	$6{\cdot}2 \pm 0{\cdot}9$	$126 \pm 9{\cdot}4$	$26{\cdot}1 \pm 1{\cdot}5$	$6 \pm 2{\cdot}2$
0·5	$152 \pm 5{\cdot}8$	$5{\cdot}5 \pm 2{\cdot}4$	$123 \pm 4{\cdot}0$	$23{\cdot}8 \pm 3{\cdot}2$	$5 \pm 0{\cdot}0$
1	$150 \pm 4{\cdot}8$	$6{\cdot}1 \pm 0{\cdot}8$	$122 \pm 4{\cdot}9$	$26{\cdot}7 \pm 4{\cdot}4$	$7 \pm 1{\cdot}1$
2	$154 \pm 0{\cdot}7$	$5{\cdot}5 \pm 0{\cdot}7$	$134 \pm 9{\cdot}2$	$27{\cdot}0 \pm 0{\cdot}7$	$6 \pm 2{\cdot}0$
4	$151 \pm 0{\cdot}3$	$6{\cdot}5 \pm 0{\cdot}7$	$136 \pm 19{\cdot}0$	$27{\cdot}0 \pm 3{\cdot}4$	$5 \pm 0{\cdot}5$
10	$151 \pm 4{\cdot}2$	$6{\cdot}0 \pm 0{\cdot}0$	$125 \pm 1{\cdot}4$	$27{\cdot}0 \pm 0{\cdot}0$	$6 \pm 2{\cdot}1$
25	$150 \pm 1{\cdot}0$	$6{\cdot}0 \pm 0{\cdot}0$	$124 \pm 2{\cdot}1$	$26{\cdot}0 \pm 0{\cdot}0$	$6 \pm 1{\cdot}0$

± = Mean s.d.

Glucagon, in doses too small to produce hyperglycaemia, is a potent stimulant of Brunner's gland secretion. Stimulation by single intravenous injection follows an all or none pattern because the response is not dose dependent. A background infusion of glucagon does not potentiate the response to single injections. Thus glucagon and secretin produce similar effects on yet another target organ.

This work was supported in part by the US Public Health Service National Institutes of Arthritis and Metabolic Diseases.

Serum Enzyme Changes during Sleep Deprivation

Substantial increases in serum creatinine phosphokinase (CPK) and aldolase activities occur in many acutely psychotic patients[1–3]. Futher investigation has shown a frequent but not invariant relationship between sleep disturbance and the serum CPK (and aldolase) activity in acutely psychotic patients[4]. In eight acutely psychotic patients, severe sleep disruption, often amounting to total insomnia with particular reductions in rapid eye movement (REM) sleep[5], was associated with high serum CPK activity. We now report that elevated serum CPK activity and aldolase activity occur in normal subjects during and after experimental sleep deprivation, though many characteristics of these increases in enzyme activity are different from those in acutely psychotic patients.

Serum CPK and aldolase activities were studied in seven normal volunteers, each sleep deprived from 40–48 h, on a research ward of the NIH Clinical Center. They included four males and three females with a mean age of 18·7 years (range, 18–21 years) who had all received a brief screening interview by one of us (D. J. K.). A complete battery of blood tests, physical examinations and the Minnesota multiphasic personality inventory showed that they were healthy college students with no remarkable psychopathology. Three pairs of subjects underwent 48 h of sleep deprivation and two subjects (including subject 3 who participated in two separate experiments) underwent 40 h of sleep deprivation. All the subjects were able to complete the experimental protocol without distress or development of psychiatric symptoms.

Blood specimens were obtained at 8–9 a.m. on the morning before the first night of sleep deprivation from all of the subjects for baseline enzyme activities. The samples obtained at 24 and 48 h in the subjects who underwent 48 h of sleep deprivation were called deprivation specimens 1 and 2 (D1, D2 respectively). Three or four specimens during the recovery period (R1–R4) were obtained from these subjects at 24 h intervals thereafter. For the two subjects, 3b and 7, who underwent only 40 h of sleep deprivation, the 48 h specimen was considered the R1 specimen. For these subjects, there was no D2 specimen. Serum from all specimens was obtained by centrifugation, frozen and coded so that all determinations of enzymatic activity were done on a blind basis.

CPK and aldolase activities were determined spectrophotometrically[6,7] and normal serum CPK and aldolase activities for fully active males and females in our labora-

Table 1. SERUM ALDOLASE AND CPK ACTIVITIES IN NORMAL MALES AND FEMALES

	Number of subjects	Mean	s.d.	Range	95 per cent upper confidence limit
		Aldolase (mU/ml.)			
Males	20	1·38	0·67	0·3–2·4	2·7
Females	20	1·73	0·73	0·5–3·2	3·2
		CPK (IU/l.)			
Males	78	39·8	19·9	12–138	80
Females	67	29·2	22·5	7–165	74

tory are given in Table 1. These values are within the same range as those found by other authors using the same methods[8,9]. The activities of serum aldolase and CPK in the subjects who underwent sleep deprivation are presented in Figs. 1 and 2. There were no apparent changes in serum CPK activity in two of the sleep deprived subjects, but most cases showed moderate alterations. In all of the subjects there were marked increases of serum aldolase activity. The serum aldolase activity after the first 24 h of sleep deprivation was significantly greater than that before sleep deprivation ($P < 0.001$). The serum aldolase activity 72 h after the end of sleep deprivation, and the CPK activity following the first 24 h of sleep deprivation and 72 h after the end of sleep deprivation, were also significantly different from baseline enzyme activities ($P < 0.05$). The aldolase activities noted in seven of eight experiments on D1 or R3 or both were quite striking because aldolase activity of greater than 5 mU/ml. is far beyond normal limits and is rarely noted even in acutely psychotic patients[1–3]. The marked increases in aldolase activity on either R3 or R4 in five cases are particularly perplexing in that these changes were occurring 72–96 h after sleep deprivation. The increases in CPK activities on D1 and R3, by contrast, were far smaller than those found in acutely psychotic patients. First, it should be stressed that daily determination of serum CPK and aldolase activity in non-psychotic psychiatric patients for periods of up to 2 months has revealed considerable stability in the activity of both enzymes so that the range of CPK and aldolase activity for a given subject is usually within 15 IU/l. for CPK and 1·0 mU/ml. for aldolase (H. Y. M., unpublished). The increases in aldolase activity during the sleep deprivation and recovery periods, however, were far beyond this range.

A number of factors which could produce increased serum enzyme activity should be considered. Severe and prolonged physical activity can produce increased serum enzyme activity[10–12] but the subjects in this study exercised only moderately in order to keep awake. Further serum CPK increases far more than serum aldolase after exhausting, short-term exercise, and the increases in aldolase after exhausting exercise were much less than those observed in the studies reported here[13].

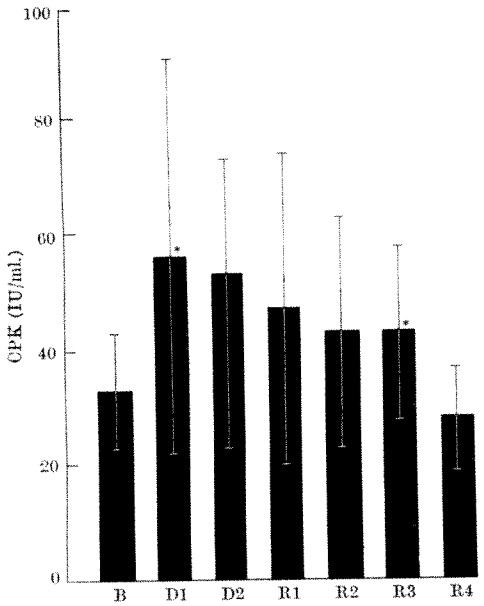

Fig. 1. CPK change during sleep deprivation. B represents the baseline data. D1 and D2 are the two deprivation days. R1–R4 represent the recovery period.

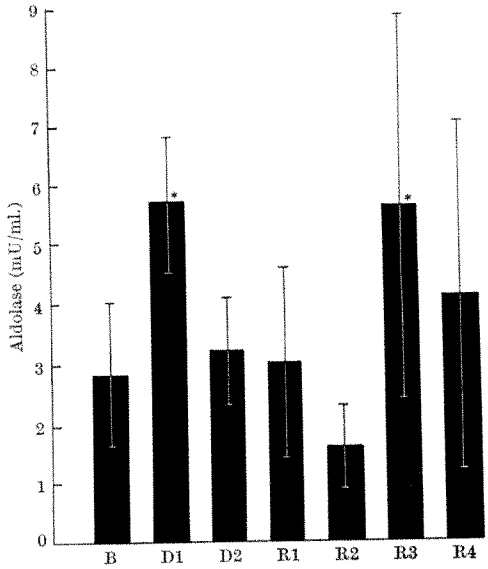

Fig. 2. Aldolase change during sleep deprivation.

Although sleep deprivation much more prolonged than we imposed here seems to produce stress-related biochemical changes, for example, increases in phosphatidyl glycerol and phosphatidic acid, decreases in cardolipin[14], and slight increases in plasma 17OH-corticosteroids[15], moderate psychic stress does not usually increase serum CPK or aldolase activity (refs. 16, 17, and H. Y. M. and S. Hassan, unpublished). Pathologic changes in skeletal and cardiac muscle, liver and the endocrine organs which have been associated with increases in serum CPK or aldolase activity, or both[18–20], would not be likely to be produced in the conditions of these experiments.

It is possible that the large increases in serum aldolase activity found at D1 and R3 are a consequence of the sleep deprivation itself. The transient nature of the increased enzyme activity suggests a temporary increase of cell membrane permeability resulting in greater escape of aldolase into the circulation as the immediate cause of the increased enzyme activity. Isoenzyme studies of the serum aldolase might make possible the localization of the tissue(s) from which the aldolase is being released in increased amounts. It would be interesting to see whether deprivation of selective stages of sleep would produce comparable results.

The relationship between the sleep disturbance and increased serum CPK and aldolase activity in the acutely psychotic patients and the serum enzyme increases in sleep deprived normal subjects is difficult to interpret. In the acutely psychotic patients, the increases in serum CPK activity are much greater relative to normal values than are the increases in serum aldolase activity[1–3]. The converse is true of the sleep deprived normal subjects. The magnitude of the increased aldolase activity after sleep deprivation was much greater than that typically found in acutely psychotic patients, even though many of those patients generally suffered much longer sleep disruption. These differences in enzyme activity between acutely psychotic patients and sleep deprived normal subjects suggest that sleep disturbance in itself may not be the cause of increased enzyme activity in the acutely psychotic patients.

We thank Mrs Suzanne Mrozak for technical assistance. This work was supported in part by a grant from the Scottish Rite Foundation and the State of Illinois.

Decreased Binding of ^{14}C-Homogentisic Acid induced by Ascorbic Acid in Connective Tissues of Rats with Experimental Alcaptonuria

ADULTS with alcaptonuria develop a destructive arthritis secondary to the deposition of a melanin-like pigment in their connective tissues, especially skin, tendon and cartilage (ochronosis). The biochemical steps leading to ochronosis involve the chemical binding of oxidized and/or polymerized derivatives of homogentisic acid (HGA), the metabolite accumulating in the blood in alcaptonuria, to these connective tissues, with subsequent physicochemical alterations in the properties of collagen[1]. HGA seems to be converted to an oxidized polymerized derivative through the formation of a labile, oxidized intermediate, benzoquinone acetic acid (BQA). Both steps in this conversion are catalysed by HGA polyphenol oxidase, a copper-requiring enzyme[2].

No effective therapy or prophylaxis for ochronosis has been reported. Ascorbic acid, which strongly reduces oxidized HGA *in vitro*, has been administered in high doses to patients with alcaptonuria without subsequent reduction in their 24 h urinary HGA excretion level[3–6]. Ascorbic acid, however, can prevent the binding of oxidized derivatives of HGA to collagen and other proteins *in vitro* (T. J. L., J. D. S. and J. E. S., unpublished). D-Penicillamine has recently been seen to form 1,4-addition products with BQA *in vitro* and it has been postulated that this compound might effectively reduce ochronosis through the formation of soluble excretable adducts, as well as by acting as a reducing agent or perhaps by inhibiting HGA polyphenol oxidase[7].

To study more directly the therapeutic potential of these two compounds, we examined the possibility that pretreating rats with experimental alcaptonuria with high doses of ascorbate or D-penicillamine would result in a measurable decrease in the binding of radioactive HGA derivatives to their connective tissues.

Forty male ACI rats, age 10–12 weeks, were randomly divided into four dietary groups: (1) Control—milled rat chow; (2) control diet with 8 per cent L-tyrosine (Nutritional Biochemicals), dry weight; (3) 8 per cent L-tyrosine + ascorbic acid (1·7 g/kg 8 per cent L-tyrosine diet, approximately equivalent to an intake of 8 g/day/70 kg body weight); (4) 8 per cent L-tyrosine + D-penicillamine (3 g with 100 mg pyridoxine/kg 8 per cent L-tyrosine diet). As previously demonstrated[8] quantitative HGA determinations of urine samples from rats on 8 per cent L-tyrosine indicated a prominent homogentisic aciduria. After maintenance on these diets for 92 days, the rats were injected intraperitoneally with ^{14}C-HGA (6·2 μCi, spec. activity 1·08 mCi/mmole) and killed 24 h later. (^{14}C-HGA Lactone (2,5-dihydroxyphenylacetic acid-[1-^{14}C]lactone, New England Nuclear Corp.) was hydrolysed in alkaline conditions with prepumped high purity nitrogen to obtain free HGA. The solution was then adjusted to *p*H 2·5 with 0·2 M HCl and sterilized and packaged by the Pharmaceutical Division, National Institutes of Health.)

Table 1. AMOUNT OF RADIOACTIVITY PRESENT IN DIALYSED CONNECTIVE TISSUE SAMPLES OF RATS WITH EXPERIMENTAL ALCAPTONURIA INJECTED WITH 1-^{14}C-HOMOGENTISIC ACID

Diet	Rat No.	Tail tendon* (c.p.m./100 mg tissue, wet wt.)	Xiphoid process* (c.p.m./100 mg tissue, wet wt.)

* Each value represents the average of two separate samples from each animal and is expressed as net counts per minute over background.

Pieces of tail tendon and xiphoid process were removed from each animal, finely minced, washed with a large volume of distilled water and then dialysed at room temperature against distilled water with three changes over 32 h. After drying for 2 h at 80° C, duplicate 100 mg samples of each specimen were dissolved in 1 ml. of 'Soluene' (Packard) by heating at 55° C for 1·5 h in scintillation vials. 'Toluene-Phosphor' was added to each vial after cooling and the samples were placed in the dark at 4° C

for 30 h. Each sample was counted for 10 min by a Packard Tri-Carb Dual Channel Liquid Scintillation Counter (model 582). Both types of connective tissue samples from rats fed 8 per cent L-tyrosine retained a 2·5 to 3·4-fold greater amount of radioactivity than those on 8 per cent L-tyrosine with supplementary ascorbate ($P < 0.001$ for tail tendon and $P < 0.01$ for xiphoid process). The amount of radioactivity retained by both types of connective tissues of rats fed D-penicillamine was not, however, significantly different from the amount retained for the 8 per cent L-tyrosine diet alone. Small amounts of ^{14}C were also retained in tissues of the control rats (receiving no L-tyrosine) although these values were not directly compared with those of the groups receiving 8 per cent L-tyrosine because the control rats probably had a much smaller body pool of HGA before injection.

This is the first report of direct measurement of the amount of binding of ^{14}C-HGA derivatives to connective tissues *in vivo* both with and without ascorbate treatment and strongly suggests that ascorbic acid reduced the total amount of binding of oxidized and/or polymerized HGA to connective tissue of rats with experimental alcaptonuria. Because the HGA-^{14}C bound to connective tissue constituted a very small fraction of the total HGA-^{14}C administered, the failure to detect differences in the urinary HGA excretion during the earlier experimental treatment of ochronosis with ascorbic acid is understandable.

The failure of D-penicillamine treatment to influence the binding of ^{14}C was unexpected. But D-penicillamine will not react with unoxidized HGA to form addition products and we have been unable to demonstrate the presence of BQA adducts with D-penicillamine in the urine or serum of alcaptonuric patients receiving this drug. Furthermore, the concentration of BQA in alcaptonuric serum is extremely low.

The animal model we used has many similarities to ochronosis[9]. Whether the administration of high doses of ascorbate to patients with alcaptonuria, particularly younger ones in whom pigmentary deposition has not yet produced clinically significant ochronosis, might be an effective method of preventing or inhibiting the deposition of ochronotic pigment in their connective tissues and, hence, delay or prevent the appearance of ochronotic arthritis remains to be demonstrated. We thank Dr George Martin for advice and for providing space in which we kept the animals used in these experiments.

Determining Body Composition by Radiation Absorption Spectrometry

THE fractional composition of a multi-component absorber can be determined from the attenuation of γ-radiation at several energies[1–6]. This technique has been used to measure the amount of bone *in vivo*[7–11]. We now show that absorption measurements at two energies accurately indicate the relative lean–fat composition of soft tissue, and we have developed a scanning method of determining fat, lean cellular and bone mineral mass *in vivo*.

The attenuation of monoenergetic radiation in a single absorber is given by

$$I = I_0 \exp(-\mu x) \text{ or } \ln I_0 - \ln I = \mu x \qquad (1)$$

where I is the beam intensity after it has passed through the absorber, I_0 is the initial unattenuated beam intensity, μ is the mass absorbance coefficient (cm²/g) of the absorber, and x is the mass per unit area (g/cm²) of the absorber in the beam. For a complex absorber the total absorption coefficient (μ_t) at any single energy is the sum of the fractional absorption contributions of the absorber components

$$\mu_t = \mu_a f_a + \mu_b f_b \ldots + \mu_n f_n \qquad (2)$$

where μ_a is the mass absorption coefficient of component a, and f_a is the fractional contribution of a to the total mass, and so on. For a material composed of n components the fractional composition is obtained from n simultaneous equations of the form of equation (1), each incorporating equation (2). In practice, measurement at more than two energies is difficult because of cumulative uncertainties. This and the scarcity of monoenergetic sources in the useful energy range (20–100 keV) generally limit composition analysis to simple mixtures.

We have used ^{241}Am (59·6 keV) and tin-filtered ^{125}I (27·4 keV) sources with a conventional detector and a single channel analyser[12,13]. Instead of solving simultaneous equations for each set of observations we used the ratio (R) of ^{125}I absorbance to that with ^{241}Am as a direct index by establishing a calibration curve relating R to composition. In soft tissue $R \simeq 2{\cdot}1$ for 100 per cent lean cellular component and $R \simeq 1{\cdot}5$ for 100 per cent fat. Because absorption coefficients of fat and lean are nearly equal with ^{241}Am γ-rays the relationship between the ratio and relative composition of a mixture is linear. Measurements of soft tissue composition by differential absorption spectrometry require high precision and accuracy because of the relatively small differences among the absorption coefficients of low Z materials at these energies.

The accuracy of this new method was high. In soft tissue phantoms (polyethylene and sodium acetate; vegetable oil and water; paraffin and water) absorptiometry indicated fractional composition with a standard error of estimate (s.e.e.) of less than 0·02 (Fig. 1) and with high correlations ($r \simeq 0{\cdot}99$). Other workers using ^{109}Cd reported high accuracy with phantoms[14]. In meat samples (fat content by lipid extraction) the measured R for 100 per cent fat was 1·52 (s.e. = 0·026) while for 100 per cent lean the value was 2·09 (s.e. = 0·016); the s.e.e. in predicting the composition of seven meat samples was 0·03. The measured values of R in the different mixtures tested corresponded closely to values derived from published absorption coefficients[15].

Initially we measured tissue composition *in vivo* at single points on human limbs. Reproducibility over several days was usually high (0·5 per cent uncertainty for R), but composition changed with small position changes. A scanning method was developed which largely eliminated this problem. A photon source (100–200 mCi of ^{125}I, or 125 mCi of ^{241}Am) and detector are mechanically linked and passed several times at uniform speed across an accessible area, usually the middle upperarm[12]. Scanning facilitates both relocation and comparisons among subjects and sites; the total tissue mass varies along the

limb but relative composition of the soft tissue in different segments is fairly uniform. More important, scanning permits measurement of the mass of the components as well as their proportions, and bone mineral can be measured as well.

Theoretically, a third energy is needed for absorption spectrometry of bone mineral together with soft tissue; but the mass absorption coefficient of the mineral is so much greater than that of soft tissue ($\times 2$ at 59·6 keV, and $\times 7$ at 27·4 keV) that the mineral absorption is sharply demarcated in the typical scan (Fig. 2), making it unnecessary in practice. The shaded area in Fig. 2 below the I_0^* baseline shows the bone mineral absorption, and is directly proportional to the mineral mass[12]. The accuracy of measurement is 1–3 per cent from studies on ashed sections of bone[16]. The unshaded area in the scan represents soft tissue absorbance and is approximately proportional to the soft tissue mass in the scan path. The ratio of ^{125}I to ^{241}Am soft tissue scan areas gives an integrated value (ΣR) indicating relative tissue composition in the scan path. The dose from such scans is about 10 mrad and is confined to a narrow (5 mm) area across the limb.

Table 1. FIVE REPEAT MEASUREMENTS IN TWO SUBJECTS OVER 9 MONTHS

	^{241}Am tissue scan		^{125}I tissue scan		ΣR	
Subject	1	2	1	2	1	2
Mean	69·6	104·5	144·2	214·2	2·070	2·045
s.d.	1·95	3·07	3·72	8·32	0·006	0·026
c.v. (per cent)	2·80	2·94	2·58	3·88	0·27	1·28

Immediate reproducibility in replicate upperarm scans ($n = 63$) was within about 0·5 per cent for soft tissue scan area, and 1–2 per cent for bone mineral using either nuclide. Long term precision was examined in replicate scans on nine subjects after a 6 month interval; the uncertainty for scan areas with either nuclide was about 4 per cent while the uncertainty in ΣR was only about 1·6 per cent. Repeated measurements on two subjects over a 9 month period, as well as results on phantoms, showed even higher precision (Table 1). Part of this uncertainty in soft tissue scan areas may reflect actual changes of tissue mass, including those arising from repositioning. In spite of these variations in tissue mass the ΣR was determined with only a 1 per cent error; this typically introduces an uncertainty of about 0·03–0·04 in fractional composition. Such an error is moderately high relative to the usual range in fat fraction (0·10–0·40).

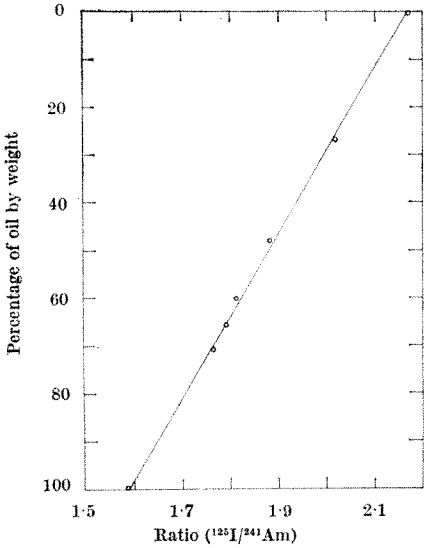

Fig. 1. Relationship between actual composition of a vegetable oil–water mixture and our measure of composition (R); accuracy of composition by absorptiometry is typically 1–2 per cent. $\Gamma = 0{\cdot}999$; s.e.e. = 1·27 per cent.

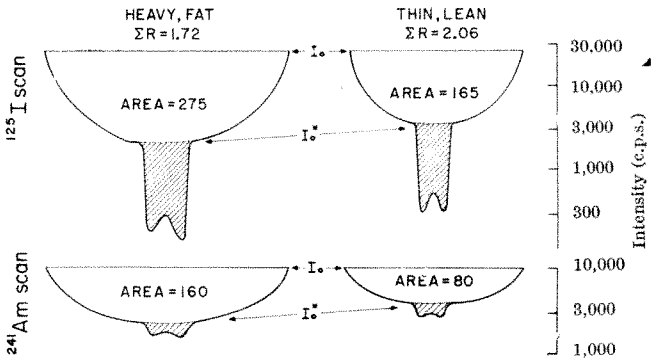

Fig. 2. Absorption scans of the upperarm in a heavy, fat person (left) and a thin, lean person (right). I_0 is the count rate level in air and I_0^* is the level adjacent to the bone. The shaded area represents absorption by bone mineral. The mineral is usually sharply demarcated in the scan and the baseline (I_0^*) is readily determined. The fat person has relatively lower tissue absorption with ^{125}I. The arm of the thin person contained about 7 per cent fat, while that of the heavy person had 65 per cent; these are the extremes of upperarm composition.

Our measurements were highly correlated with some indirect measures of composition. In nineteen young adults the correlation between tissue absorbance and upperarm circumference was 0·98, while the correlation with triceps skinfold (Lange caliper) was −0·91. Upperarm composition in these subjects was about 16 per cent fat, 81 per cent lean tissue and 3 per cent bone mineral.

Thiaminase I in the Development of Cerebrocortical Necrosis in Sheep and Cattle

MEMBERS of the B group of vitamins are synthesized by ruminal microflora[1], and it has therefore been assumed[2] that ruminants do not require thiamine in their diet. In cerebrocortical necrosis of sheep and cattle[3], however, tissue thiamine levels are low, resulting in cellular anoxia, characteristic damage to the cortical neurones[3], raised

blood keto-acids and lactate, and lowered transketolase[4] activity. Moreover, plasma pyruvate kinase activity is elevated[5], indicating a severe disturbance in carbohydrate metabolism. The decrease in thiamine levels was shown to result from the presence of a thiaminase in the ruminal contents of affected animals[6,7], and we have since found this enzyme in all cases of cerebrocortical necrosis examined in this laboratory. It was present not only in the ruminal contents, but throughout the alimentary tract. We have now examined further the nature of this enzyme.

Thiaminase activity (type I or II) was assayed by extracting labelled 4-methyl-5-hydroxyethylthiazole released by the enzyme into ethyl acetate, in which thiamine itself is insoluble. Materials for thiaminase assay, such as rumen liquor, faeces or bacterial cultures, were suitably diluted or extracted with citrate–phosphate buffer (*p*H 6·4, 0·1 M) and 0·5 ml. of the extract mixed with 0·5 ml. of a solution of substrates in the same buffer. The substrate solution contained 100 μg of [*thiazole*-^{14}C]-thiamine (Radiochemical Centre, Amersham) with an activity of 50 nCi, and 38 μg of nicotinic acid per ml. After incubation for 1 h at 37° C, 2·0 ml. of ethyl acetate was added and the mixture was well shaken. After centrifugation at 2,500 r.p.m. for 5 min an aliquot of 0·5 ml. of the ethyl acetate layer was withdrawn and mixed with 10 ml. of scintillator fluid for determination of radioactivity. A blank without enzyme was always included. The number of counts gave a measure of the thiaminase activity, and was linear with time of incubation and concentration of enzyme.

If the thiaminase was of type I (thiamine : base 2-methyl-4-aminopyrimidine-5-methenyltransferase, EC 2.5.1.2), it would require a co-factor for activation[8–10], for purified thiaminase I itself does not have any thiamine splitting activity[11]. When cerebrocortical necrosis rumen liquor was dialysed against phosphate buffer (*p*H 6·5, 0·01 M) for 36 h at 4° C all thiaminase activity was lost. Restoration of activity by a number of possible co-factors, such as nicotinic acid (and to a lesser degree nicotinamide), aniline, pyridine and 2-methyl-4-amino-5-aminomethylpyrimidine, showed the enzyme to be of type I. Cysteine, cystine, 2-methyl-4-amino-5-hydroxymethylpyrimidine, glutathione, *p*-aminobenzoic acid, hydroxyproline, 1-methylnicotinamide and lysine were without measurable effect.

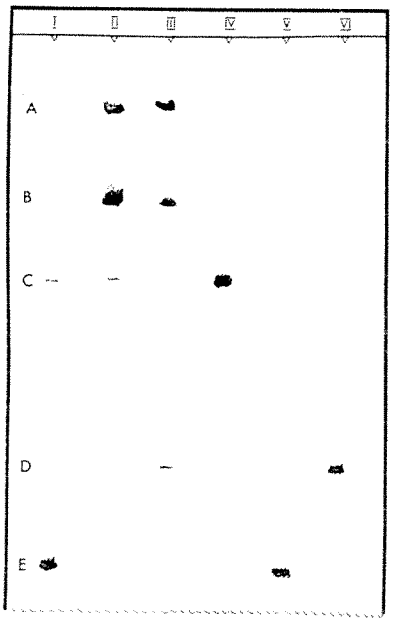

Fig. 1. Idealized autoradiogram of extracts from incubation of cerebrocortical necrosis rumen liquor with various substrates. I, With [*thiazole*-^{14}C]thiamine (ethyl acetate extract); II, [*pyrimidine*-^{14}C]thiamine (defatted alcohol extract); III, 6-^{14}C-nicotinic acid and thiamine (defatted alcohol extract); IV, thiazole or [*pyramidine*-^{14}C]thiamine; V, 4-methyl-5-hydroxy-[2-^{14}C]thiazole; VI, [6-^{14}C] nicotinic acid. Chromatograms (descending) were developed in *n*-butanol–acetic acid–water (4 : 1 : 1) for 16 h. Autoradiograms were obtained by exposure to 'Kodirex' X-ray film for 48 h.

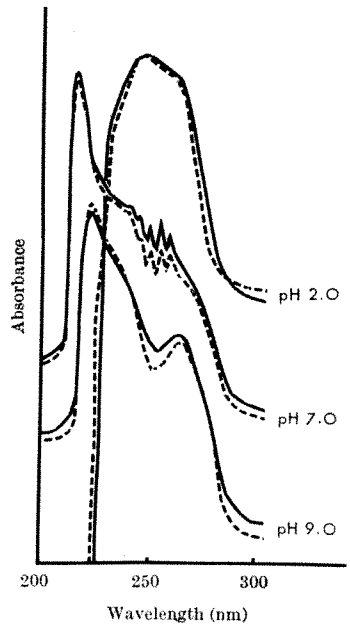

Fig. 2. Ultraviolet absorption spectra wavelength (nm) of pyrimidinyl-nicotinic acid. (*a*) from cerebrocortical necrosis rumen liquor (continuous line) and (*b*) synthetic (broken line) at *p*H 2·0, 7·0 and 9·0.

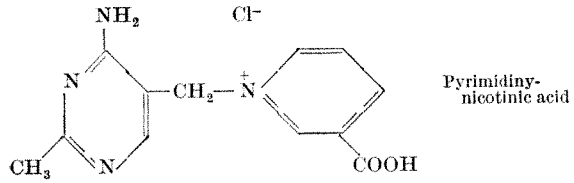
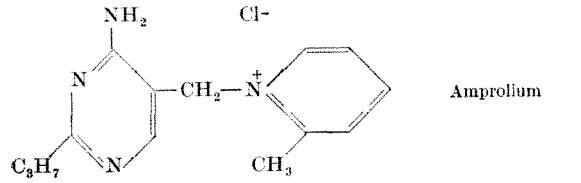


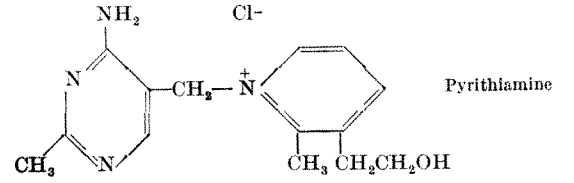
When the ethyl acetate extract from the incubation of cerebrocortical necrosis rumen liquor with [*thiazole*-^{14}C]-thiamine was chromatographed and autoradiographed, a single radioactive spot (apart from a trace of residual thiamine), consistent with the R_f of 4-methyl-5β-hydroxyethyl thiazole (Fig. 1*E*), was seen. When the pyrimidine moiety was labelled instead—by synthesizing [*pyrimidine-2-methyl*-^{14}C]thiamine from [2-^{14}C]acetonitrile—and the defatted alcoholic extract similarly chromatographed and autoradiographed, two radioactive spots *A* and *B* were seen. In separate experiments it was found that spots *A* and *B* were interchangeable, and that their relative concentrations depended on the *p*H of the extract. If the extract was treated with hydrochloric acid, only spot *A* was seen; whereas both spots *A* and *B* occurred when the extract was neutral. When cerebrocortical necrosis rumen liquor was incubated with thiamine and ^{14}C-labelled nicotinic acid (Radiochemical Centre, Amersham), and treated as before, two radioactive spots consistent with spots *A* and *B* were seen (Fig. 1).

Spots *A* and *B* were characterized as pyrimidinyl-nicotinic acid by synthesis of this compound from 2-methyl-4-amino-5-bromomethylpyrimidine and nicotinic acid, or by treatment of a mixture of thiamine and nicotinic acid with sulphurous acid, as described by Matsukawa[12]. Pyrimidinyl-nicotinic acid was further characterized by its positive reaction to Dragendorff reagent, and its greenish blue fluorescence under long wavelength ultraviolet light after being sprayed with alkaline ferricyanide. The ultraviolet absorption spectrum of the compound isolated from cerebrocortical necrosis rumen liquor (spots *A* and *B*) was identical to that of synthetic pyrimidinyl-nicotinic acid (Fig. 2).



As a model for thiaminase I activity, thiamine and nicotinic acid were incubated with the culture medium from the growth of *Bacillus thiaminolyticus*. Similar patterns of degradation to those described here were seen.

Spots *A* and *B* are taken to be the spots described by Murata[11] as Pm-X and Pm-NiA.



It is possible that this compound has antithiamine properties, for it has elements of similarity to pyrithiamine

Pyrimidiny-nicotinic acid

Amprolium

Pyrithiamine

and amprolium, both known to be thiamine antagonists. If this were so, the presence of thiaminase I in the rumen could bring about rapid thiamine deficiency. Not only would the supply of thiamine be cut off, but active antagonists would be produced which would further deplete tissues of thiamine—a situation in some ways similar to the induction of experimental cerebrocortical necrosis by administration of amprolium to calves and lambs[13].

Cerebrocortical necrosis of sheep and cattle therefore seems to be another example of the growing list of diseases caused by thiaminases: Chastek paralysis of foxes, thiaminase disease of poultry[14] caused by *Bacillus aneurinolyticus*, the nervous disorders of cats and dogs[15] fed canned fish diets, and thiaminase disease in man[16–18]. Further work on assessing the antithiamine index of pyrimidinyl-nicotinic acid and isolation of the causative agent is in hand.

We thank Professor Kiku Murata, of the Faculty of the Science of Living, Osaka City University, for specimens of *B. thiaminolyticus*, and Dr R. G. Osbond of Roche Products Ltd for generous gifts of 2-methyl-4-amino-5-hydroxymethyl and aminomethyl pyrimidines.

Placental Transfer and Metabolism of 4-^{14}C-Cortisol in the Pregnant Monkey

The concentration of cortisol in human maternal plasma exceeds that of foetal plasma by as much as two to five-fold[1–3]. This difference has been attributed primarily to the large quantity of non-diffusible cortisol in the maternal circulation—that is, cortisol bound to transcortin (cortisol binding globulin), an α-globulin with selective affinity for cortisol[4]. This concept was challenged by the studies of Gold *et al.*[5], who demonstrated that the concentration of unbound Porter–Silber chromogens in foetal plasma was lower than that found in maternal plasma, suggesting that simple differences in binding globulin concentrations alone cannot account for the distribution of cortisol between maternal and foetal compartments. The more rapid disposition of cortisol by the foetal–placental unit could account, in part, for the differences in cortisol concentration in the mother and foetus.

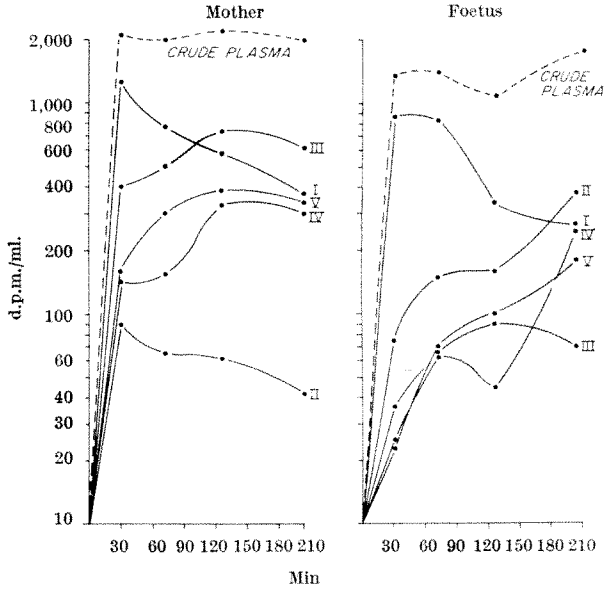

Fig. 1. Radioactivity in sequential maternal and foetal crude plasma samples, and in plasma extracts 1–5 after a single maternal infusion of 4-^{14}C-cortisol at time 0.

Quantitative information concerning this question is at present not obtainable in the human because of the inaccessibility of the foetus and the necessary limitations on human experimentation. As shown by the present study, however, such data can be obtained in a subhuman pregnant primate where it is possible simultaneously to sample maternal and foetal compartments *in situ* after the infusion of tracer amounts of labelled steroid to the mother.

Pregnant rhesus monkeys estimated to be at term (150–160 days) were anaesthetized with intramuscular piperidine hydrochloride and the uterus was exposed by laparotomy. The bidiscoid placentas and the interplacental vessels were identified by transillumination of the uterus. Usually three to four pairs of interplacental vessels are present, each pair consisting of a branch of the umbilical artery and vein. The myometrium overlying a pair of interplacental vessels was incised and a short segment of one vessel was dissected free from its position between the chorion and amnion. The vessel was cannulated with a No. 19 polyethylene catheter, so that we were able to collect foetal blood samples without entering the amniotic cavity. The foetus was then manoeuvred so that the foetal breech was held firmly against an area of

uterine wall free of placenta. An incision was made through the uterine wall and foetal membranes over the area of the foetal perineum. The foetal tail was delivered and, by means of firm traction on the tail, the foetal breech was held tightly against the uterine wall, thus preventing leakage of amniotic fluid. If the foetus was female, an episiotomy was performed and a No. 15 polyethylene tube was inserted through the urethra into the bladder and anchored in place with sutures. In the case of a male foetus, a small polyethylene catheter was inserted into the bladder via the prostatic urethra following a technique described by Chez and Hutchinson[6]. The maternal bladder was catheterized and a branch of the maternal saphenous vein was also cannulated.

Using this experimental model, 5·0 μCi 4-^{14}C-cortisol (specific activity 10 mCi/mmole) was infused into the maternal circulation for 3 min and sequential samples were taken of foetal and maternal blood and foetal and maternal urine. In each experiment foetal viability was monitored by intermittent measurement of the *p*H of blood obtained from the interplacental vessels. At the end of the experiment a living foetus was delivered by Caesarean section.

Table 1. SOLVENT EXTRACTION SEQUENCES FOR PARTITIONING OF PLASMA AND URINE SAMPLES

Extract	Solvent	Volume ratio	*p*H	Presumptive designation
1	Dichloromethane	10 : 1	7·0	Unconjugated "low polar"
2	Ethyl acetate	5 : 1	7·0	Unconjugated "high polar"
3	Dichloromethane	10 : 1	5·0	Glucuronides "low polar"
4	Ethyl acetate	5 : 1	5·0	Glucuronides "high polar"
5	Ethyl acetate	5 : 1	1·0	"Sulphates"

Each plasma and urine sample (0·1 ml.) was counted for crude radioactivity by direct addition to counting vials containing 15 ml. of a water miscible scintillator system (dioxane–cellosolve); vials were counted in a liquid scintillation spectrometer (Nuclear–Chicago, model 720) at a counting precision of ± 2 per cent and an efficiency for ^{14}C of 80 per cent. The samples were corrected for quenching. Each foetal and maternal plasma and urine specimen was then subjected to a serial extraction sequence of solvent partitioning as shown in Table 1. Extract 1 was obtained by extraction with dichloromethane at *p*H 7·0 and the aqueous residue was extracted with ethyl acetate at *p*H 7·0, resulting in extract 2. After hydrolysis with β-glucuronidase 200 U/ml. at *p*H 5·0 for 48 h at 25° C, extraction with dichloromethane and ethyl acetate at *p*H 5·0 gave extracts 3 and 4 and, finally, addition of saturated NaCl and H_2SO_4 at *p*H 1·0 for 48 h at 25° C accompanied by ethyl acetate extraction produced extract 5. After the serial extraction sequence the solvent was removed by evaporation and each extract counted for radioactivity as described previously.

After infusion of the labelled cortisol into the maternal venous system, radioactivity was detectable in foetal plasma at 10 min. A comparison of extractable radioactivity in maternal and foetal plasma (Fig. 1) shows that, following maternal injection, extract 1 radioactivity, presumably cortisol or cortisone, disappears more rapidly from the foetal circulation than from maternal circulation. Extract 2 was the principal metabolite in foetal plasma, whereas it was only a small fraction of the maternal metabolites of radiocortisol. By contrast, extract 3 represented the principal fraction in maternal plasma. Urine specimens collected simultaneously from mother and foetus indicated extract 1 radioactivity as the main excretory product of maternal urine (Fig. 2). In the foetus, however, the principal excretory product was extract 2.

This study is the first to provide data on the simultaneous metabolism and removal rates of radiocortisol from the mother and foetus in any animal species. Although several possibilities have been considered to account for the differences in maternal and foetal plasma concentrations of cortisol, these studies strongly suggest that such differences are partly a consequence of the more rapid rate of removal of cortisol from foetal plasma. This interpretation of the data is based on the assumption that cortisol and cortisone are the major constituents of extract 1. The designation of extracts shown in Table 1 follows that described by Aarskog[7], who used the same solvent extraction sequence. But the activity measured in various extracts may represent several metabolites, the specific nature of which will require further study.

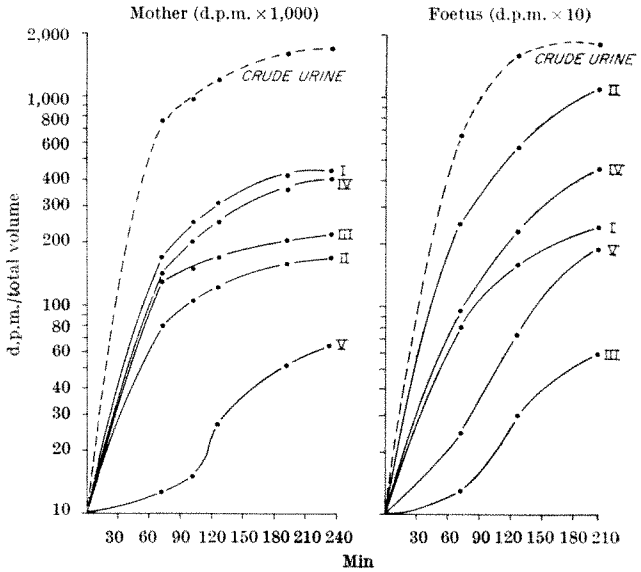

Fig. 2. Radioactivity in sequential maternal and foetal crude urine, and in urine extracts 1–5 after a single maternal infusion of 4-^{14}C-cortisol at time 0.

This study also reveals significantly different metabolic pathways for the removal of radiocortisol from maternal and foetal plasma. Whereas maternal plasma cortisol is metabolized mainly through glucuronide conjugation (extract 3), the principal foetal metabolite of cortisol is not a glucuronide but, rather, a metabolite (extract 2) somewhat more "polar" than cortisol, possibly 6-β-hydrocortisol. While this finding is consistent with earlier studies indicating that the foetus is deficient in enzymes required for glucuronide conjugation[8], it is also clear from the present study that the foetus or the foetal–placental unit has an alternative and apparently efficient mechanism for disposition of cortisol. These differences are further supported by the data concerning the foetal urinary radiometabolites of cortisol where extract 2 accounts for more than 50 per cent of extractable radioactivity.

In Vitro Support System for the Study of Blastocyst Differentiation in the Mouse

DURING the early implantation stage in the mouse several events in the differentiation of the embryo are initiated. Once the zona pellucida has been lost, attachment to the uterine epithelium occurs, the inner cell mass comes to assume its mesometrial orientation[1], trophoblastic giant cells develop, differentiation of the endoderm begins and the inner cell mass undergoes changes leading to egg cylinder formation. The *in vitro* culture of the attachment stage would allow direct observation and analysis of some of these events and an experimental investigation of the conditions influencing them. Retransfer of eggs to a receptive host animal in order to follow through the effects of experimental manipulations on earlier stages could also, in some cases, be eliminated if *in vitro* development of early implantation stages could be obtained.

Blastocysts cultured in a drop of serum-supplemented medium under liquid paraffin can undergo a form of attachment to the floor of the culture vessel[2]. When this occurs the trophoblast usually migrates out over the glass, pulling the blastocyst down and flattening it, and so disrupting normal organization. A three dimensional culture system has been devised in which development of the attachment stage can occur, with the maintenance of more normal organization, and in which the blastocyst is held in a constant orientation for cinemicrography. This report describes briefly the degree of differentiation occurring in this system and some cinemicrographic observations on the mature blastocyst.

Our principal requirements of a three dimensional culture system for blastocyst development were transparency, a suitable surface for trophoblast attachment and compatibility with culture conditions. One of the materials best fulfilling these requirements was found to be the soft, transparent lens fibre material from the bovine eye. Blastocysts were injected from a mouth controlled pipette into a small fragment of this material placed in a culture chamber suitable for cinemicrography. Earle's BSS and 10 per cent calf serum were added around the lens material and the culture was gassed with 10 per cent CO_2 in air. Control cultures were carried out in small drops of the same medium under the same gas phase. Material for histological examination was fixed in Clarke's fluid and stained with Ehrlich's haematoxylin. For cinemicrography the culture chamber was placed on a microscope enclosed in a warm box at 37° C and time lapse recordings were made at 30 s intervals. To follow relative changes in position of different components of the blastocyst, one of the trophoblast cells was marked as a reference point by the micro-injection of a drop of inert oil using a technique developed in this laboratory[3] (unpublished work of I. B. W., E. Bolton and R. H. Cuttler).

Fig. 1. Formation of endoderm. i, Inner cell mass; p, proximal endoderm; d, distal endoderm; g, trophoblast giant cells.

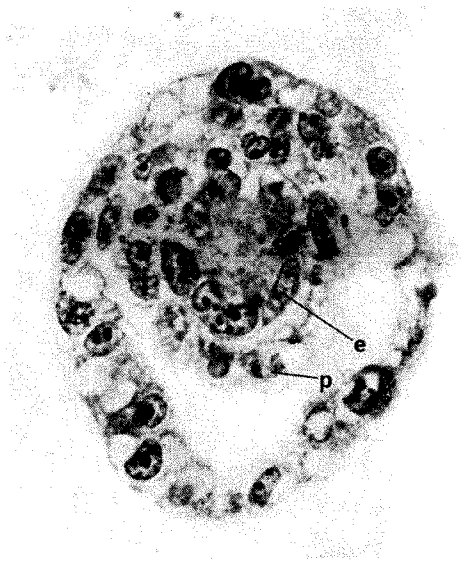

Fig. 2. Formation of egg cylinder. The embryonic ectoderm (e) shows a typical radial arrangement and is surrounded by the characteristic vacuolated cells of the proximal endoderm (p).

Blastocysts were recovered from the uterus 84 h after the estimated time of ovulation and cultured in the eye lens material or as controls for up to 48 h before fixation for histological examination. After loss of the zona, blastocysts in the control cultures either attached and flattened with loss of normal organization[2], or remained unattached and retained their normal shape. In the latter case, no differentiation and very little growth of the inner cell mass occurred and often the inner cell mass was found to have dispersed itself round the inside of the trophoblast shell. Blastocysts in the lens material did undergo differentiation similar in part to that seen when eggs are transferred to ectopic sites[3,4]. Proximal and distal endoderm were found (Fig. 1) and egg cylinder formation was initiated (Figs. 2 and 3). Even if organization failed, growth of inner cell mass derivatives continued (Fig. 4).

These observations suggest that two of the require-

ments for the onset of blastocyst differentiation are attachment and the maintenance of organization. The importance of attachment for the initiation of differentiation has also been suggested before. Tarkowski[5] has shown that rat eggs transferred to the mouse differentiated only in those cases where attachment was successful. When there was no attachment the inner cell mass sometimes spread out and dispersed as in some of the blastocysts in our control cultures, which are comparable with those shown by Tarkowski (ref. 5, Plate 1 and Figs. *A*, *C* and *F*). The difference between flattened blastocysts where no embryonic differentiation is apparent and blastocysts cultured in lens material where organization is maintained suggests that normal cellular relationships are vital in inner cell mass differentiation, as they are in many developing systems.

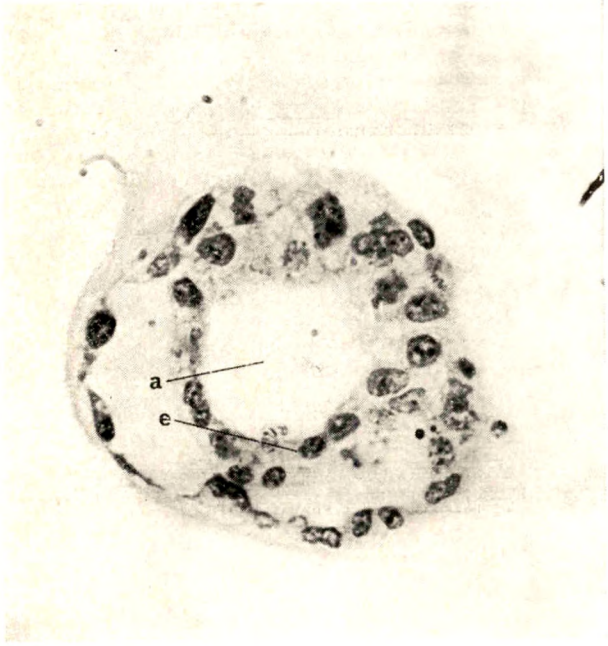

Fig. 3. Pro-amniotic cavity formation. Embryonic ectoderm (e) encloses the pro-amniotic cavity (a).

Cinemicrographic observations on the mature blastocyst in the lens material, after the loss of the zona, revealed several cell activities. During one 12 h recording period the blastocyst underwent three rapid contractions followed by a slower expansion as described by Cole[6]. The cells of the inner cell mass could be seen to be in a constant state of agitation and to push out blunt pseudopods. As a result of this type of activity the inner cell mass, although remaining a discrete group of cells, changed shape several times and actually moved bodily around inside the trophoblast "shell", finally coming to rest some 90° from its original site in a position underlying a region of trophoblast not in close contact with the lens material. The change in position was confirmed by reference to the injected marker drop. The outer membrane of the trophoblast cells pulsated, particularly in those regions where there was no close contact with the lens material; larger hyaline pseudopodia were occasionally pushed out and moved about in an exploratory fashion before being retracted.

The behaviour of the blastocyst as observed *in vitro* corresponds well with histological information on blastocyst structure. Potts and Wilson[7] have shown that the cells of the inner cell mass in the late pre-implantation stages are only loosely associated with each other and with the trophoblast and this is reflected in the way the

Fig. 4. Disorganized growth. Trophoblastic (t) and inner cell mass elements (i) are still visible.

inner cell mass cells seem free to move over each other. At the time of attachment the inner cell mass is often found to be haphazardly positioned in relation to the mesometrial/anti-mesometrial axis. Kirby, Potts and Wilson[1] suggest that mesometrial orientation of the inner cell mass is achieved by migration of the inner cell mass round the inside of the trophoblast "shell"; the results obtained here show that the inner cell mass is capable of such movement.

The gradients, or other factors, which determine that the inner cell mass will come to rest in a mesometrial position are not known. In histological preparations of attaching blastocysts *in utero*, fixation shrinkage frequently causes the blastocyst to pull away from the epithelium. It is often found that it is in the mesometrial region of the trophoblast that separation occurs most readily, suggesting that attachment in this region is weak or not yet complete. It seems from the film recording that the region of trophoblast where there is least contact with the eye lens material is more "attractive" to the inner cell mass than regions which have more contact. Because the mesometrial side of the blastocyst is one where attachment seems to be weakest *in utero* this could explain why the inner cell mass comes to lie mesometrially.

It seems feasible that changes can occur in the trophoblast cells on attachment which could lead to the setting up of gradients in the trophoblast shell to which the inner cell mass would be capable of responding. The nature of such gradients is speculative and could involve several factors such as a change in trophoblast metabolism on attachment, promotion of exchange of materials between the trophoblast and the substratum or a change in surface free energy or surface potential of the trophoblast cells, leading to variations in adhesiveness between those parts of the trophoblast which have attached and those which have not. If inner cell mass orientation was due to differential adhesiveness of the trophoblast shell, it might be expected that the trophoblast of the attached lateral and anti-mesometrial aspects of the blastocyst would be less adhesive to the inner cell mass than the unattached mesometrial region so that, as shown for fibroblasts[8], the cells of the inner cell mass would move up the gradient of adhesion and come to lie mesometrially, at least in the mouse.

This work was carried out while E. J. J. was in receipt of an SRC research studentship.

Chromosome Size and Hypodiploidy

IN chromosome preparations from peripheral lymphocytes a certain number of aneuploid metaphases are usually found (about 10–20 per cent hypodiploid and 1–2 per cent hyperdiploid chromosome sets). These aberrations are usually the result of technical artefacts. In cases where a true numerical chromosomal aberration can be expected these unavoidable artefacts can cause erroneous results.

In 1967 Pegoraro *et al.* collected all reported cases of chronic myeloid leukaemia, where the complete chromosomal analysis, based on the Denver classification system was given. They investigated whether the chromosome gain or loss, coincident with the deterioration of the haematological system, showed any distinct pattern. Combining additional and missing chromosomes in the different groups (*A*–*G*), they found no relation to the size of the groups in question. They rather found a close correlation between decreasing chromosome size and the tendency to be gained or lost. The authors therefore assumed that mechanical factors play an important part in chromosomal non-disjunction. Considering only the distribution of the missing chromosomes in the authors' table, however, such a correlation was not seen by us.

Recently Neurath *et al.*[2] tried to establish a correlation between chromosome loss, chromosome size and the age and sex of the individual (7,067 mitoses were studied). Even though they investigated only hypodiploid mitoses of healthy persons, they found the same connexion between decreasing chromosome size and increasing chromosome loss as did Pegoraro *et al.* The only deviation from a nearly linear correlation was the very high loss of *G* group chromosomes exceeding the expected value. Their results were independent of the person's age; the well known tendency towards higher chromosome loss with increasing age[3,4] was verified.

The findings of both groups prompted us to compare our data collected from photographs of 4,884 mitoses. They derived from blood lymphocyte cultures from healthy persons and healthy mothers of mongoloid children (20–37 yr). The mitoses had been collected in a few months and used for chromosome association studies under different preparation techniques; macrocultures in mothers[7], macro and microcultures in controls[5,6]. Because macrocultures and microcultures did not show any different pattern of chromosomal loss, the results could be combined for this study. We found a hypodiploidy rate of 12·9 per cent (Neurath 16·3 per cent) indicating that it stemmed mostly from preparation and not from mitotic non-disjunction.

Our findings are compiled in Table 1, which shows the percentage participation of the different chromosome groups (*A*–*G*) in the diploid chromosome complement and both the raw values of missing chromosomes and the percentage deviation from the expected numbers. The percentage loss difference was calculated by the formula: $L = 100\,(o-e) : e$, where o is the observed number of missing chromosomes for each particular group and e is the number expected on the basis of a random loss. Besides the metaphases with 45 chromosomes, we considered separately the mitoses which lost up to six chromosomes (columns 4–7), so as to investigate the possibility of a combined loss of several chromosomes.

In the female population a group of 33 normal controls and 26 normal mothers of mongoloid children were combined[7] because the pattern of chromosome loss was nearly identical. This means that there seems to be no increased tendency towards mitotic chromosomal non-disjunction in mothers of mongoloid children.

Table 1. DISTRIBUTION OF CHROMOSOME LOSS IN METAPHASE PLATES OF PERSONS WITH A NORMAL KARYOTYPE

Number of:													
Missing chromosomes		122		269		391		337		759		1,096	
Hypoploid metaphases		122		269		391		192		439		631	
Metaphases examined		1,474		3,410		4,884		1,474		3,410		4,884	
Percentage hypodiploidy		8·3		7·9		8·0		13·0		12·9		12·9	

In agreement with the other authors we found a significantly smaller loss of *A* and *B* chromosomes than would be expected by chance. *C*, *E* and *F* chromosomes were more frequently lost than expected. The highest relative loss rate was observed in the *E* group. Unexpectedly, acrocentric chromosomes of the *D* and *G* group were seldom missing but they were not as strongly retained as the large chromosomes of the *A* and *B* groups. There was no significant difference between males and females (*C* and *G* groups have been corrected for the presence of a second *X* or a *Y* chromosome). There were no obvious shifts in the chromosome loss ratios between metaphases with 45 and those with 40–45 chromosomes. A tendency towards a combined chromosome loss could not be found. Our results agree very well with those on the hypodiploid mitoses of Pegoraro *et al.*, but they disagree with the results of Neurath *et al.* We were not able to establish a significant correlation between chromosome loss and size, nor did we see the extremely high loss of *G* group

chromosomes in our material. This seems to be quite significant, for we have found that the common chromosome aberration in human meningeal tumours is the absence of a single *G* chromosome[8]. This finding was confirmed in more than forty tumours and is to our knowledge the first case of a uniform chromosomal aberration in a human solid tumour[9].

It is interesting that the metacentric *E* chromosomes show relatively the highest loss rate, because a loss of *E* chromosomes is reported to be a rather frequent finding in the stemlines of chronic myeloid leukaemia at the beginning of exacerbation[10]. On the other hand, the nucleolus organizing chromosomes, the *D* and *G* chromosomes, are missing relatively seldom. This phenomenon, as well as the close association of these chromosomes in the spread metaphase plate, may arise from the stickiness of adherent nucleolar material.

Our results confirm that the numerical loss of chromosomes shows a certain pattern, but they suggest that this pattern may be a consequence of several different (mechanical) factors and not only dependent on the chromosome size.

This study was supported by the Deutsche Forschungsgemeinschaft and will be published in detail later.

Very Early Replication of Scrapie in Lymphocytic Tissue

THE incubation period of scrapie in susceptible animals is extremely long[1] and its apparently non-viral behaviour is also well known[2]. Biochemical investigations have usually concentrated on brain tissue when histopathological lesions are maximal[3], but it seems important experimentally to locate other sites of active replication. Involvement of lymphocytic tissues has been known for some time[4–6] and agent distribution in organs of the mouse after peripheral subcutaneous inoculation suggested a pathogenesis in which the agent localized and multiplied in lymphocytic tissue before being disseminated to sites of secondary replication such as neural cells[7]. A ten-fold multiplication in the spleen was observed within 8 weeks of inoculation. A genetically controlled delay in the time of an early rise in agent concentration in spleen has been reported after intracerebral or intraperitoneal inoculation[8,9].

Reproducible titres and quickest response are achieved by the intracerebral route[10] which suggests that the pathway of pathogenesis is well defined and amenable to quantitative measurement. Levels of scrapie activity in mouse spleen and brain, two sites of high activity in the infected animal[7], have been determined at intervals from 1–56 days following intracerebral inoculation of groups of inbred C57 mice with inocula prepared from 10^{-1}, 10^{-2}, 10^{-3} and 10^{-4} dilutions of a standard brain homogenate pool. Seven mice were killed at each interval and whole homogenates of pooled brains or spleens without centrifugation titrated in Swiss White mice[10]. Total levels of activity are expressed in doses of ID_{50}/0·03 ml. inoculum of a 10^{-1} dilution of the standard brain homogenate.

Table 1. TOTAL LEVELS OF SCRAPIE ACTIVITY IN MOUSE BRAIN AND SPLEEN 18 DAYS AFTER INTRACEREBRAL INOCULATION

Inocula	Inoculum dose	Activity in spleen	Multiplication	Activity in brain
10^{-1}†	5·3*	5·2	—	3·9
10^{-2}	4·3	5·2	0·9	3·5
10^{-3}	3·3	4·2	0·9	2·2
10^{-4}	2·3	3·7	1·4	1·6

* All levels expressed as $\log_{10}$ (ID_{50} doses/0·03 ml. inoculum of a 10^{-1} dilution of standard brain homogenate).
† Dilution of brain homogenate.

Spleen activity initially increased for 18 days at a mean rate of 0·16 $\log_{10}$/day, response being identical following the 10^{-1} and 10^{-2} dilutions, with evidence of a ten-fold multiplication (Table 1) quite unrelated to the level of brain activity. Mice receiving a 10^{-1} or 10^{-2} inoculum then maintained a constant level ($10^{5\cdot2}$) in spleen although it continued to rise slowly with the higher dilutions until the same plateau was reached in 42 and 52 days respectively for the 10^{-3} and 10^{-4} inoculum representing even higher multiplication of the original dose. In brain after an initial fall to a residual level, activity began to increase when the spleen attained about $10^{4\cdot5}$ doses. The relative delays in the initial rise in brain activity and its subsequent increase compared with spleen are shown in Table 2. The increase in brain titre, 0·05 and 0·09 $\log_{10}$/day, is lower than the initial change in spleen titre and decreases with time.

Table 2. TIME PERIODS FOR BRAIN OR SPLEEN ACTIVITY TO ATTAIN CERTAIN LEVELS AFTER INTRACEREBRAL INOCULATION

Inoculum	Inoculum dose ($\log_{10}$)	Time for spleen to attain $10^{4\cdot5}$ doses (days)	Time for spleen to attain original inoculum (days)	Time for brain to attain original inoculum (days)
10^{-2}	4·3	14	8	30
10^{-3}	3·3	22	8	38
10^{-4}	2·3	42	7	46

Table 3. TOTAL LEVELS OF SCRAPIE ACTIVITY IN MOUSE SPLEEN AFTER INTRACEREBRAL INOCULATION OF SHEEP OR GOAT SCRAPIE

Inoculum	Time after inoculation (months)	Inoculum dose ($\log_{10}$)	Total activity in spleen ($\log_{10}$)
Suffolk sheep	1	2·2*	3·2*
	2	2·2	4·3
Goat	1	2·9	4·2
	2	2·9	4·2

Expressed as $\log_{10}$ (ID_{50} doses/0·03 ml. inoculum of a 10^{-1} dilution of sheep or goat brain homogenate).

The products of a replication process are therefore present in spleen active in the period 2–3 weeks following injection. No biochemical data exist for actual synthesis in spleen. In its functional behaviour active material could be selectively adsorbed from lymphocytic and gland tissue so that spleen activity is only an indicator of the general level. Comparable levels of activity at similar times in these locations[7] (D. L. M. and A. McL. D., to be published) increase the scale of effective multiplication at an early stage over the whole animal. The identical response following inocula derived from a 10^{-1} or 10^{-2} homogenate indicates a limited number of replication sites. Any replication of residual inoculum in brain following intracerebral inoculation is likely to be extremely slow. After inoculation of a 10^{-1} homogenate an observed slight elevation of levels of activity over that of a 10^{-2} homogenate for the first 40 days can be accounted for by higher levels of residual activity remaining in the brain. It seems necessary for active material to be transported by lymph drainage to lymphocytic tissue where localization and replication take place fairly rapidly and a modified scrapie active material is then gradually returned to the brain in increasing amount. This activated scrapie can now presumably multiply in brain tissue, eventually

causing neuronal damage possibly through metabolic malfunction with the appearance of clinical disease.

If efficiency of localization in lymphocytic tissue is an important factor, the expected time sequence for the critical titre determining rise in brain activity to be reached in spleen following various routes of inoculation would be intracerebral, intraperitoneal and subcutaneous. From experimental data available[7,8] it could take between 28 and 56 days after subcutaneous inoculation while the incubation periods are similar for both the subcutaneous and intraperitoneal routes. Splenectomy of mice before or after intracerebral inoculation has no effect on the incubation period[11] which suggests that the spleen is accumulating agent that has been synthesized elsewhere. Conversely, because the system is saturated with a 10^{-1} or 10^{-2} inoculum, removal of a site of synthesis may have only a marginal effect so that splenectomy performed with higher dilutions of inoculum might be more effective.

We have proposed that during the replication cycle in lymphocytic tissue the scrapie agent is modified. An extreme case is provided by the first passage in mouse of scrapie derived from Suffolk sheep or goats[12] with incubation periods of 13–14 and 11–12 months respectively. Within one month spleens affected by goat scrapie inoculum had reached the plateau levels followed a month later by those receiving sheep scrapie (Table 3). The incubation periods for the recipient mice in the titration groups were longer than expected for mouse passaged material (ME7)[12]. The extent of histopathological lesions in the brains was about midway between the generalized distribution of ME7 and the localized subcortical distribution expected in a first sheep to mouse passage[12]. Applying various criteria a partial adaptation of the species specific scrapie to the mouse and replication is proceeding within 4 to 8 weeks after inoculation.

Another species adapted scrapie inoculation into the host species can be compared with mouse scrapie. Levels of activity found in goat spleen at 10, 14 and 18 weeks after intracerebral inoculation of a 10^{-1} dilution of scrapie goat brain homogenate were equivalent to the activity injected into the animal[13]. These observations were very similar to those obtained with mouse scrapie following a 10^{-1} brain homogenate inoculum.

Whatever scrapie source or route of inoculation is considered it seems that localization in the lymphocytic tissue is essential for initiation of replication and modification. The multiplication process is completed within relatively short periods, comparable with those found with oncogenic viruses, so scrapie replication can no longer be regarded as associated with long time scales. The rate of multiplication is slow, but this agrees with the general low level of scrapie activity compared with virus infections. These low rates of synthesis *in vivo* cast doubt on the possible success of culturing scrapie in cells, or visualization of the agent by electron microscopy. Biological testing is still the only criterion for scrapie potency, but the conceptual change in time scale and tissue type provides a new basis for biochemical investigation for it is conceivable that only a small proportion of the products of synthesis or replication is biologically active. There is undoubtedly a transference of scrapie potent material from localized sites in lymphocytic tissue to the brain[7], and now that the time scale is better defined it should be possible to determine the transfer stage. Tissue biopsy also now seems a possible approach to the diagnosis and progression of the natural disease in sheep. We thank Dr J. T. Stamp, Dr R. M. Barlow, Dr J. M. K. Mackay and Dr J. T. Vantsis for discussion.

Antigen Binding Cells in Tolerant Animals

The immune response involves the appearance of antibody secreting cells as well as antigen binding cells. Antibody secreting cells can be counted *in vitro* using Jerne and Nordin's local haemolysis in gel (LHG) assay[1], and are then called plaque forming cells (PFC). Antigen binding cells can be recognized by their ability to bind particulate antigens such as sheep red cells (SRB) to their surfaces and have been named rosette forming cells (RFC)[2,3]. It is likely that RFC represent a mixture of antibody secreting cells and non-antibody secreting cells. Howard *et al.*[4] studied the RFC response in the spleens of mice tolerant to pneumococcal polysaccharide. Although serum antibodies could not be seen in these animals a considerable number, larger, in fact, in "tolerant" than in optimally immunized animals, of RFC was found. They explained these findings on the basis that antibody secreting cells existed but that the humoral antibodies produced were neutralized extracellularly by persisting undegraded antigen.

We have studied the cellular basis of tolerance to another polysaccharide antigen. Two to five months old CBA mice were used. Tolerance was induced by repeated injections of 3 mg of alkali detoxified polysaccharide from *E. coli* O55 : B5 (CPS)[5] given 5 times in 3 mg doses during 14 days and maintained by weekly injections of 3 mg of CPS. The animals tolerant to CPS showed a normal PFC response to SRC. The number of PFC in the spleens was tested by the LHG assay of Jerne and Nordin[1] as modified by Mishell and Dutton[6]. Conjugation of the CPS to SRC was performed as described by Möller[7]. CPS stimulates 19S antibody synthesis exclusively for a prolonged period, so only direct PFC were studied[8]. For detection of RFC a slight modification of the centrifugation-resuspension method described by McConnell *et al.*[9] was used. The CPS was absorbed to CBA mouse erythrocytes using the same method as with SRC[7].

Spleen cells from normal, immune and tolerant animals were assayed for the presence of PFC and RFC. In immune animals the assay was done 5 days after one injection of 0·01 mg of CPS at the peak of the PFC response[5]. In one of the tolerant groups, "tolerant mice A", the assay was done 5 days after the last injection of the tolerance maintaining dose of 3 mg of CPS. In the other tolerant group, "tolerant mice B", the animals received an injection of 0·01 mg of CPS 7 days after the last injection of 3 mg and were tested 5 days later.

In non-immune animals the mean number of PFC was $1{\cdot}4/10^6$ spleen cells and of the RFC $115/10^6$ spleen cells. Optimally immunized animals showed a mean number of 154 PFC/10^6 spleen cells and of 382 RFC/10^6 spleen cells (Table 1). In the "tolerant mice A" group the appearance of PFC was completely inhibited except in one animal in which a small response was detected. The RFC, on the other hand, were not abolished; instead

Table 1. CELLULAR IMMUNE RESPONSE IN SPLEENS OF MICE IMMUNIZED WITH *E. coli* POLYSACCHARIDE

	PFC/10^6 spleen cells	RFC/10^6 spleen cells
Normal mice	0·15 ± 0·15 (1·4)	2·06 ± 0·07 (115)
Tolerant mice A	0·13 ± 0·13 (1·3)	2·21 ± 0·14 (164)
Tolerant mice B	0·73 ± 0·19 (5·4)	2·37 ± 0·04 (235)
Immune mice	2·19 ± 0·08 (154)	2·58 ± 0·06 (382)

The figures are given in $\log_{10}$ values for the mean ± standard error. The corresponding antilogs for the mean are given in parentheses. Tolerant mice A were tested 5 days after the last tolerance maintaining dose of 3 mg of CPS. Tolerant mice B were given 0·01 mg of CPS 7 days after the last injection of 3 mg of CPS and assayed 5 days later. Immune animals were tested 5 days after the injection of 0·01 mg of CPS.

there was a tendency for an increase in number compared with the unimmunized mice, with a mean of 164 RFC/10^6 spleen cells. In the "tolerant mice B" group a mean number of 5,4 PFC/10^6 spleen cells and of 235 RFC/10^6 spleen cells was demonstrated. The number of RFC in this group is significantly increased over background values but is not as high as in optimally immunized animals (Table 2).

Table 2. *P* VALUES FOR DIFFERENCES IN MEAN NUMBER OF RFC BETWEEN VARIOUS GROUPS OF MICE

	P value
Normal—tolerant A	Not significant
Normal—tolerant B	$P < 0.005$
Normal—immune	$P < 0.001$
Tolerant A—tolerant B	Not significant
Tolerant A—immune	$P < 0.05$
Tolerant B—immune	$P < 0.02$

For designation of the various groups see Table 1.

These findings cannot be explained on the basis suggested by Howard *et al.*[4] that the tolerant state is brought about by neutralization of antibodies by excess antigen. Thus tolerance to endotoxin appears to inhibit selectively the steps leading to the appearance of antibody secreting cells, without affecting those resulting in RFC to a similar extent. In fact, Howard has recently reinvestigated the immune status in mice tolerant to pneumococcal polysaccharide and has also found antigen binding cells in situations where the antibody secreting cells are paralysed by very high antigen doses (personal communication).

There are several alternative explanations for our findings. The receptors on the RFC in tolerant animals may be directed to other antigenic determinants than the antibodies secreted by the PFC in immune animals. These determinants may occur in such a low density on the sensitized SRC that antibodies against them do not cause plaques. Tolerant animals may contain cells actually secreting antibodies directed against the same determinants as antibodies producing plaques in immune animals but of such a low affinity[10] that they are detected as RFC but not as PFC. Or tolerance induction could lead to blockage of antibody secretion without affecting division and differentiation of precursor cells for antibody production. These three possibilities are unlikely for reasons which will be fully discussed elsewhere (O. S., unpublished).

A further possibility is that tolerance is caused by the inhibition of division and differentiation of precursor cells for antibody production. The RFC in tolerant animals may in this case be formed by thymus derived lymphocytes or by bone marrow derived lymphocytes which do not give rise to PFC. Recent findings have shown that thymus derived and bone marrow derived lymphocytes cooperate in the antibody response to certain antigens[11]. The lipopolysaccharide antigen of *E. coli* is not dependent on thymus derived lymphocytes to induce a humoral antibody response (Andersson and Möller, personal communication), but this does not necessarily imply that there are no receptors for the antigen among the thymus derived lymphocytes. The independence of thymus derived lymphocytes for an adequate immune response to CPS may be related to the fact that the structure of this antigen is characterized by repeating units of identical determinants. Such an antigen may bind well to bone marrow precursor cells with multivalent receptors and stimulate them to antibody production in the absence of thymus derived lymphocytes. If thymus derived lymphocytes were thus stimulated to respond in tolerant animals, they would appear as RFC but not as PFC, which may explain the discovery of RFC in tolerant animals. Recently, experiments involving isoantigenic markers have revealed that a high proportion of the RFC that appear in mice immune to SRBC are made up of thymus derived lymphocytes[12]. But the percentage inhibition of RFC against CPS after treatment with anti-theta serum were −2 to +8 per cent and −16 to +18 per cent for tolerant and immune animals respectively compared with 20–32 per cent for RFC against SRC (O.S., unpublished). The RFC against CPS are therefore not likely to be thymus derived lymphocytes but rather lymphocytes from bone marrow.

It is possible that a high dose of antigen will only stop division of bone marrow derived lymphocytes with receptors for the antigen above a certain level of affinity. Such cells would give rise to PFC after an optimal immunization dose. Bone marrow derived lymphocytes with receptors of lower affinity would be stimulated to divide but not to produce antibodies after optimal stimulation. In tolerant animals these cells are not prevented from dividing because they escape tolerance induction in consequence of the low affinity of their receptors. Such cells could explain the RFC in tolerant animals. If this alternative is correct it would also imply that a level of affinity, sufficiently high to bind the antigen to the cell surface, is not high enough to induce antibody production.

Opsonin Depletion after Surgery

PREVIOUS studies have demonstrated a state of decreased host resistance after surgery[1–3]. While the precise pathophysiological causes of this phenomenon are unknown, recent findings suggest that depression of the reticuloendothelial system (RES) may be involved[4,5]. Intravascular phagocytic clearance of foreign colloidal and particulate matter by the RES is highly dependent on the presence of circulating serum or plasma factors called "opsonins"[6–8], so RE depression after surgery may be related to depression of opsonic activity. Indeed, the role of opsonins in resistance

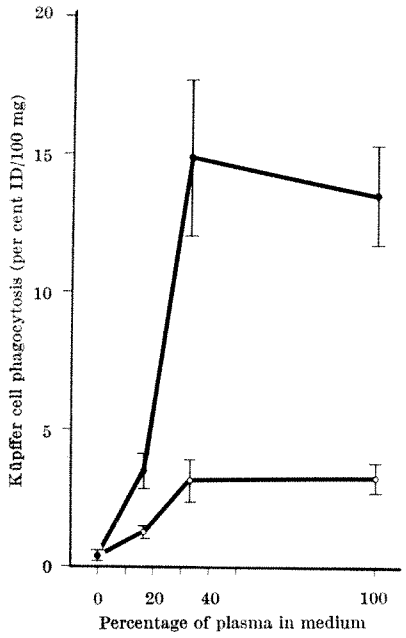

Fig. 1. Hepatic Küpffer cell phagocytosis of test lipid emulsion in normal (●) and 30 min post-surgery plasma (○) as a function of the incubation plasma concentration. Uptake is expressed as the percentage of the injected dose phagocytosed per 100 mg liver (per cent ID/100 mg). Each point represents the mean ± standard error of six to twelve samples.

to infection[9], and the findings of marked RE depression buring periods of plasma opsonin depletion[6,7], suggest that ooth the reduced resistance and the depressed RE activity dbserved after surgery may be related to a functional depression of the opsonic system.

To test this hypothesis, plasma opsonin activity was evaluated in normal rats and in rats at a post-surgery interval (30 min) known to be associated with significant RE depression[4]. Furthermore, because a depression in opsonin activity could reflect either the absence of plasma opsonin or the presence of an inhibitory substance in the blood, the potential inhibitory effect of post-surgery serum on *in vivo* RE activity was evaluated. Non-fasted male Holtzman (Holtzman Co., Madison) rats weighing 250–350 g were used. Serum and plasma (heparinized) were obtained by vena cava puncture with the use of light ether anaesthesia. Plasma opsonic activity was evaluated by an *in vitro* tissue slice technique, in which the comparative ability of normal and post-surgery plasma to stimulate Küpffer cell phagocytosis was determined[6,7,10]. Slices of normal liver were prepared with a Stadie–Riggs tissue slicer and incubated with a ^{131}I-labelled lipid emulsion in 3 ml. of heparinized (50 USP/ml.) incubation medium containing 0, 16·7, 33·3 or 100 per cent plasma. The plasma was diluted with Krebs–Ringer phosphate (*p*H 7·4). All samples were gassed with 95 per cent O_2 and 5 per cent CO_2 and incubated with oscillation at 37° C for 30 min. At the end of the experiment, the liver slices were removed, washed in isotonic saline and analysed for particle uptake as previously described[6,7,10]. Plasma opsonic activity was assessed in terms of the degree of phagocytosis, and Küpffer cell phagocytosis of the colloid was expressed as the percentage of the injected dose phagocytosed per 100 mg tissue (per cent ID/100 mg). The radio-iodinated test emulsion used *in vitro* was a gelatinized ^{131}I "RE test lipid emulsion"[6,7,10]. It was prepared as an anhydrous base with glycerol, ^{131}I-triolein (Mallinckrodt Nuclear, St Louis), and lecithin mixed in a ratio of 10:10:1 by weight, respectively[10,11]. Before use, the lipid base was diluted with a 0·1 per cent gelatine containing 5 per cent dextrose and water solution previously adjusted to *p*H 7·4. In this study, 2,000 μg of the lipid emulsion was added to each incubation flask. Liver slice uptake of the ^{131}I lipid emulsion was determined with an 'Auto-Gamma' crystal scintillation counter (Nuclear–Chicago, DesPlaines).

The effect of normal and post-surgery serum on RE activity was evaluated with a slight modification of the carbon clearance technique[12], with which the rate of colloid clearance from the circulation before and after the intravenous injection of serum was determined. Rats were injected with colloidal carbon (Gunther–Wagner, Hanover, Germany) at a dose of 16 mg/100 g body weight, and the rate of disappearance of carbon from the circulation was determined by spectrophotometric analyses of serial 0·1 ml. aliquots of whole blood[13]. Carbon concentration was plotted semi-logarithmically against time and the $t/2$ for the vascular clearance of the foreign colloid by the RES was determined. From the clearance curve, the "phagocytic index" K was calculated according to the expression

$$K \text{ (phagocytic index)} = \frac{\log C_1 - \log C_2}{T_2 - T_1}$$

where C_1 and C_2 represent the circulating colloid concentration at times T_1 and T_2, respectively. K can also be calculated from the $t/2$ value, according to the expression:

$$K \text{ (phagocytic index)} = \frac{0{\cdot}301}{t/2}$$

where 0·301 is the $\log_{10}$ of 2, and the half-time is in minutes. In the present study, the K for the vascular clearance of a single dose of carbon was determined before (0–7 min post-carbon injection) and after (8–14 min post-carbon injection) the intravenous injection of serum or saline. Saline or serum injection was performed 7 min after carbon injection at a dose of 0·5 ml./100 g body weight, and comparisons between the pre and post-injection K values were made.

The surgery consisted of mid-line laparotomy (5 cm) with brief intestinal manipulation under ether anaesthesia. The incision was closed with silk suture. Control rats were exposed to a comparable ether anaesthesia stress.

Küpffer cell phagocytosis of the lipid emulsion was significantly ($P < 0{\cdot}001$) enhanced by the presence of normal plasma compared with Krebs–Ringer phosphate (Fig. 1). Phagocytosis in a 33·3 per cent normal plasma concentration was 42-fold greater than in the absence of plasma. In contrast to the marked opsonic stimulation of phagocytosis by normal plasma, minimal stimulation of phagocytosis was induced by plasma obtained at 30 min post-surgery. Uptake in 33·3 per cent post-surgery plasma was only 21 per cent of that observed in comparable concentrations of normal plasma.

Table 1. EFFECT OF NORMAL AND POST-SURGERY SERUM ON RATE OF COLLOIDAL CARBON CLEARANCE FROM THE CIRCULATION

Group evaluated	Material injected (intravenous)	Vascular clearance rate Pre-injection (K_1)	Post-injection (K_2)
Control	Saline	0·011 ± 0·008	0·012 ± 0·002
Normal	Serum	0·017 ± 0·002	0·029 ± 0·003
Post-surgery	Serum	0·011 ± 0·002	0·013 ± 0·002

K_1 reflects clearance between 0–7 min after carbon injection, and K_2 reflects clearance between 8–14 min after carbon injection. Saline, normal serum, or 30 min post-surgery serum was injected at 7 min post-carbon injection. Each group represents 3–9 animals. Means ± standard error of the means are presented.

Injection of saline or 30 min post-surgery serum in the course of carbon clearance did not significantly alter the rate of carbon clearance as indicated by the respective pre-injection (K_1) and post-injection (K_2) values for the phagocytic index K (Table 1). By contrast, the injection of normal serum in the course of carbon clearance significantly enhanced ($P < 0{\cdot}05$) the subsequent rate of carbon clearance from the circulation.

These results confirm and extend previous findings on the importance of plasma or serum opsonic activity for Küpffer cell phagocytosis[6,7,10], and show that 30 min after surgery in the rat there is a marked depression in circulating opsonin activity. The failure to alter the rate of carbon clearance by the injection of post-surgery serum in the course of colloid clearance suggests a minor role

for a serum inhibitory substance in the altered phagocytic activity after surgery.

Metabolic Effects of Polychlorinated Biphenyls in the American Kestrel

POLYCHLORINATED biphenyls (PCB) have been widely found in wildlife samples[1,2]. PCB are used as plasticizers in plastics, resin and chlorinated rubber[3]. They have been recommended for improving lindane residues[4] and have been shown to increase the insecticidal properties of DDT and dieldrin[5]. PCB are highly stable, insoluble in water and soluble in lipids; so that they can persist and undergo biological magnification in the environment.

Sax[6] reported the toxicity of chlorinated biphenyls as moderate to high. One PCB has been shown to produce chick hydropericardial oedema and growth depression proportional to dietary levels (200 and 400 p.p.m.) of the toxicant[7]. These effects were accompanied by such pathological changes as: cream-coloured pancreas, enlarged haemorrhagic kidney, enlarged adrenal gland, small spleen, dermatitis, defeathering and transient changes in blood glucose, haemoglobin and haematocrit levels. Intramuscular injection of PCB has been shown to increase the rate of steroid metabolism in bird liver homogenates[1] as has been shown for organochlorine pesticides[8]. Although a cause and effect relationship has not been demonstrated, PCB residues have been associated with decreasing populations of fish-eating birds and birds of prey[1].

American kestrels were trapped, allowed to acclimatize for a week, paired (one male and one female per cage), acclimatized for another week and then placed on *ad libitum* experimental diets. The kestrels' diet consisted of one day old dead cockerels. The dead cockerels were injected in the breast region at either 0·5 p.p.m. or 5·0 p.p.m. (w/w) of either 'Aroclor 1254' or 'Aroclor 1262' (Monsanto trade names for PCB containing 54 per cent chlorine and 62 per cent chlorine respectively) dissolved in sesame oil. The higher dose is roughly equivalent to 2 mg/kg PCB to each kestrel. Cockerels for control kestrels were injected with sesame oil only. It is assumed that the kestrels consumed essentially all of the dietary 'Aroclor', for the only parts of the cockerel not eaten were the beaks and feet, and the pellets regurgitated by the kestrels consisted of cockerel down. Each pair was kept in a burlap-covered $6 \times 6 \times 8$ foot wire cage and fed experimental diet once a day for 5 months. At the end of the test period, the birds were killed, livers removed, and the microsomal fraction was prepared and incubated as described by Conney and Klutch[9]. Radioactive oestradiol and its metabolites were extracted with dichloromethane and separated by paper chromatography[10] with changes in procedure as reported previously[1,8].

Histological examination was carried out on kestrels fed 5 p.p.m. 'Aroclor 1254' for 14 days. A central portion of the liver was removed immediately after death and fixed in Carnoy's fluid for 45 min. Sections were cut at 5 μm. All sections were treated with deoxyribonuclease (0·1 mg/ml. in 0·1 M phosphate buffer (*p*H 7·5)–0·1 per cent gelatine–0·03 M $MgSO_4$) for 3 h at room temperature to remove DNA which would otherwise stain with azure B. All sections were then stained in azure B (0·1 per cent in 0·1 M citrate buffer, *p*H 4·0) for 2 h at 40° C, washed briefly with water and differentiated overnight with *t*-butyl alcohol[11]. The density of the staining with azure B was measured cytophotometrically at 545 nm (ref. 12). Ten readings of the per cent transmission of a standard area of cytoplasm were made for each of five control and five experimental livers. The mean for control birds was 39·7 ± 3·3 whereas for the experimental birds it was 26·8 ± 3·6. An analysis of variance of both the individual values and the means gave calculated F values which exceeded the 0·005 tabular F; we therefore conclude that the decrease in percentage transmission is a consequence of the presence of more cytoplasmic RNA in the 'Aroclor'-treated kestrels.

Table 1. *In vitro* MICROSOMAL BREAKDOWN OF OESTRADIOL
Amount of polar metabolites formed in nmoles/g microsomal fraction (sample size, 4 for each group)

Diet	Mean	s.d.
Control	0·00	0·00
0·5 p.p.m. 'Aroclor 1254'	13·65	7·35
5·0 p.p.m. 'Aroclor 1254'	60·50	31·20
0·5 p.p.m. 'Aroclor 1262'	19·05	11·50
5·0 p.p.m. 'Aroclor 1262'	47·95	25·45

A dose-dependent *in vitro* breakdown of oestradiol to a more polar metabolite occurred in livers from kestrels fed either 'Aroclor 1254' or 'Aroclor 1262' (Table 1). There was no apparent difference between the effects of the two 'Aroclors' nor was there any difference between sexes. No such conversion took place in the livers from the control birds.

The increase of hepatic enzyme activity can thus be correlated with an increase of cytoplasmic RNA. Proliferation of the endoplasmic reticulum of rat liver cells following the administration of chlordane[13] and DDT[14] has been noted although these changes were not quantified. Our findings suggest the physiological actions of PCB are similar to those of DDT and its metabolites. This industrial contaminant should be considered as an additional burden to the ecosystem comparable with that imposed by the organochlorine pesticides.

We thank Dr T. J. Cade for help in providing the kestrels and Monsanto for supplying 'Aroclors 1254 and 1262' and technical bulletins. This work was supported by the National Institutes of Health, and carried out while one of us (D. B. P.) was an established investigator, American Heart Association.

Connectance of Large Dynamic (Cybernetic) Systems: Critical Values for Stability

MANY systems being studied today are dynamic, large and complex: traffic at an airport with 100 planes, slum areas with 10^4 persons or the human brain with 10^{10} neurones. In such systems, stability is of central importance, for instability usually appears as a self-generating catastrophe. Unfortunately, present theoretical knowledge of stability in large systems is meagre: the work described here was intended to add to it.

Most of these large systems, often biological or social, are grossly non-linear, which increases the difficulties associated with them. Here we consider linear systems merely as a first step towards a more general treatment.

We have attempted to answer: What is the chance that a large system will be stable? If a large system is assembled (connected) at random, or has grown haphazardly, should we expect it to be stable or unstable? And how does the expectation change as n, the number of variables, tends to infinity?

Monte Carlo-type evidence[1,2] had suggested that the probability of stability decreased rapidly as n was increased, in some cases perhaps as fast as 2^{-n}, an exponentially-fast vanishing of the chance that the system will be stable. This result, however, was for systems that were fully connected, where every variable had an immediate effect on every other variable. While this case is obviously important in theory, it is not the case in most large systems in real life: not every person in a slum has an immediate effect on every other person, and not every cell in the brain directly affects every other cell. The amount of connectedness ("connectance") is often far below 100 per cent. We have studied how such incomplete connectance affects the probability of a system's stability.

Let the linear system's state be represented by the vector $\mathbf{x}$ ($= <\mathbf{x}_1, \ldots, \mathbf{x}_n>$, where each $\mathbf{x}_i$ is a variable, a function of time), and its changes in time by the matrix equation

$$\dot{\mathbf{x}} = A\mathbf{x}$$

To "join the variables at random" is to give the elements in A values taken from some specified distribution. "Non-connexion from $\mathbf{x}_i$ to $\mathbf{x}_j$" corresponds to giving the element a_{ji} the value zero. Thus, if the specified distribution has a peak at zero, sampling from it will give the equivalent of a dynamic system with many non-connexions. The connectance, C, of the system can then be conveniently defined as the percentage of non-zero values in the distribution. Thus, if the coefficients are drawn from a distribution with 99 per cent zeros, and if $n = 1{,}000$, then each line of the equation would contain about ten non-zero coefficients, corresponding to a system in which each variable is directly affected by about ten other variables.

Because our work was essentially exploratory, we used the distribution in which the non-zero elements were distributed evenly between $-1{\cdot}0$ and $+1{\cdot}0$. The elements in the main diagonal, corresponding to the intrinsic stabilities of the parts, were all negative, distributed evenly between $-1{\cdot}0$ and $-0{\cdot}1$. Thus each sampled value of A corresponded to a system of individually stable parts, connected so that each part was affected directly by about C per cent of the other parts.

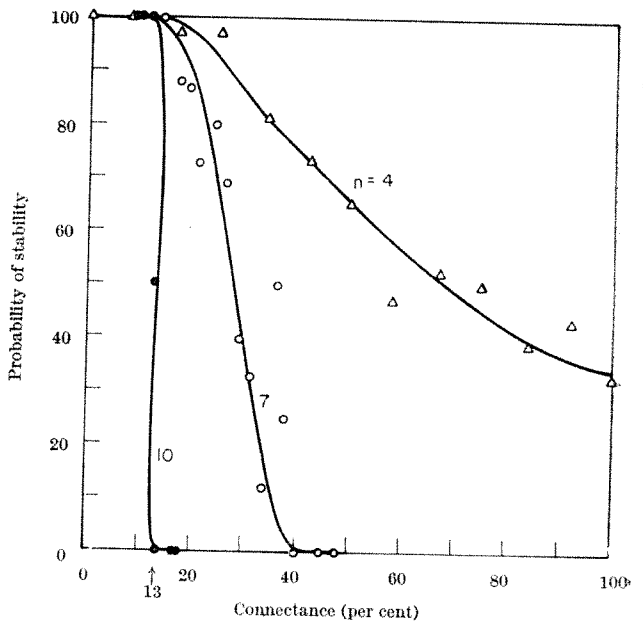

Fig. 1. Variation of stability with connectance.

On a digital computer, a value for n was given and a value for C. Random numbers appropriately distributed were then sampled to provide a matrix A. Hurwitz's criterion was applied to test whether the real parts of A's latent roots were all negative (the stable case) and the result recorded. Further samples, giving further As, allowed the probability of stability (P) to be estimated. The probability was then re-estimated for another value of C, and so on, until the variation of P with C became clear.

The results showed the feature that we wish to report here. As the system was made larger, a new simplicity appeared. Fig. 1 shows a selection of the results, enough to illustrate the principal fact.

When $n = 4$, the probability that the system would be stable depended on C in a somewhat complex curve (which could perhaps be predicted exactly). But as n increases, the curve changes shape rapidly towards a step-function, so that even when n is only 10, the shape might be so regarded, at least for some practical purposes. Thus, even at $n = 10$, questions of stability can be answered simply by asking whether the connectance is above or below 13 per cent: 2 per cent deviation either way being sufficient to convert the answer from "almost certainly stable" to "almost certainly unstable".

The matter is being investigated further, but it may be of general interest to notice that this work suggests that all large complex dynamic systems may be expected to show the property of being stable up to a critical level of connectance, and then, as the connectance increases, to go suddenly unstable.

This work was supported in part by the US Office of Scientific Research.

Book Reviews

PERSPECTIVES OF POPULATION

Population, Resources, Environment

Issues in Human Ecology. By Paul R. Ehrlich and Anne H. Ehrlich. (Series of Books in Biology.) Pp. 383. (Freeman: San Francisco and Reading, September 1970.) 84*s*.

Life Without Birth

A Journey Through the Third World in Search of the Population Explosion. By Stanley Johnson. Pp. xxii + 364 + 24 photographs. (Heinemann: London, September 1970.) 50*s*.

In spite of the objective evidence of an increase in the expectation of life from about twenty-five years in 1750 to about sixty years in 1970, the controversy over the possibility of improving the human condition continues to rage. *Population, Resources, Environment* is a notable contribution in the tradition of Malthusian pessimism. This beautifully produced book, appropriately swathed in a jet-black dust-cover, is a catalogue of apparently insuperable obstacles strewing the paths to further progress in the directions in which man's endeavours are leading. Although each individual extrapolation is suitably qualified by reference to ways in which the obstacles might be circumnavigated, the pall of gloom gathers deeper over the reader the further he advances.

There is a great deal of well arranged basic information on demography, ecology and food technology which is neutrally reported and attractively presented. This part of the work is useful textbook material at the sixth-form level. It is in assessing the significance of current trends and projecting these into the future that the authors' judgment becomes most obtrusive and at the same time conjectural.

The total available resources of the Earth do not suffice to develop duplicates of industrial societies all over the globe, even for the current level of population. Fuel, dozens of metals, productive land, marine resources are all inadequate and the authors document their case with care and ingenuity, interleaving the text with "boxes" containing capsulated case-histories and elementary lessons in fundamentals such as the law of natural selection, thermodynamics and the chemistry of herbicides. Many pollution hazards are detailed. Some of these hazards such as residual insecticides are grave threats to the ecological balance of life on Earth; other hazards described are speculative, of local significance only or are highly fanciful. In their anxiety to document the case against "growth mania", the Ehrlichs fail to make appropriate distinctions of this kind.

The section on family planning and population control suffers most severely from lack of balance. A table (p. 242), purporting to show the progress achieved by population programmes by 1969 measured against the targets set, conveys an impression of total failure, but all the figures quoted for 1969 are in fact from earlier years—in some cases for years before the programme being assessed started operation. Instead of a careful appraisal of the problems and principles involved in the task of providing family planning services to total populations of agricultural societies and of inducing them to make use of them early in the process of family formation, the Ehrlichs devote the bulk of the space available to a consideration of dramatic and quite impractical strategies, some of which belong in the pages of the more lurid science fiction magazines. Indeed, valuable and comprehensive as this book is, it consistently fails to achieve a detached and balanced view of hazards and remedies because of the over-developed sense of doom and drama which pervades it. As if the limitations of the Earth and the byproducts of man's struggle to master it were not alarming enough, the authors throw in for good measure the possibilities of political and natural catastrophe which the future may hold—nuclear and biological warfare on the one hand, world inundation when Antarctica slumps into the sea or the Arctic ice-cap melts on the other. At the end of the book, the Ehrlichs call for de-development of the industrial countries. They may be right that this is the only course that will avert world disaster, but it seems the least feasible of all.

I approached Stanley Johnson's book with antipathy. After flicking through the pages I concluded that this was a dilettante travelogue loosely linked with human interest anecdotes of the hardships of population growth and as meandering as the author's journey. I left it with the conviction that it is by far the best non-technical book on the current population crisis yet available. Mr Johnson is not a specialist in any aspect of population study, but he is a specialist in observation, in insight and in communication.

Life Without Birth is indeed a travelogue, documenting the population scene in twelve countries (including Red China whose Tibetan profile the author glimpsed against the sky from Nepal). Each short chapter extracts what is relevant from the history and political alignment of the country and knits it together with population problems policies and programmes through conversations with officials and academics and the kaleidoscope of impressions that impinge on the traveller and which Stanley Johnson so unerringly dissects into its components.

The book has an air of innocence about it which is quite unusual. The author seems to have approached his task with no preconceptions and, if his repeated modest disclaimers are to be accepted, no relevant technical knowledge. If this approach has led to a somewhat uncritical acceptance of much that he was told by officials and advisers with their own preconceptions to advance or interests to guard, it has nonetheless resulted in a series of remarkably clear and comprehensive pictures of the past, present and future of population growth and policy in the countries visited. Although it is packed with factual information this never becomes overwhelming because it is placed in its logical setting and becomes part of an absorbing story. Whether it is a device or the very truth, the author's technical innocence enables him to take the reader's hand and lead him through the task of understanding the elementary demographic theory without which no population story can be told.

The contents of the book defy summary, for it has no didactic purpose and no capsulated messages. It is for those who like to form opinions on the basis of fact rather than slogans. It is thus an old-fashioned book and it is a surprise to find its author is only 29 years old. It is also a well written book, rising to the level of the genuinely epigrammatic time and again, and it is a courageous book, mincing no words in castigating Pope Paul VI for Humanea Vitae, or Westminster (perhaps a little unfairly) for the lack of official support for Hong Kong's family planning work.

Although written for a lay readership, *Life Without Birth* should be read by every "population expert" and "multidisciplinary family planning worker" in the world, for it has the three-dimensional quality which comes from the correct use of perspective.

D. Wolfers

NEW SCHOOL CHEMISTRY

Nuffield Advanced Science

Chemistry. (Penguin: Harmondsworth, Middlesex, 1970. Published for the Nuffield Foundation.)

Students' Book 1: Topics 1 to 12. Pp. 410. 30*s*.

Teachers' Guide 1: Topics 1 to 12. Pp. 342. 30*s*.

Ion Exchange: A Special Study. Pp. ix+109. 13*s*.

THESE books are the first to be published of a complete set which will cover the requirements for Nuffield A-level chemistry. The remainder will appear in the near future: a second *Students' Book* and *Teachers' Guide*, a *Book of Data*, four more *Special Studies* (biochemistry, chemical engineering, food science, and metallurgy), experiment sheets, and some programmed texts.

The content of the books is excellent. I regret that I cannot praise them without some not-so-faint damns. The first criticism is the perennial one of cost. The explanatory notes for the new London A-level chemistry syllabus, for example, contain frequent reference to the Nuffield course; and there is no doubt that the *Students' Books* would serve very well as texts for students coping with the new courses. But to equip my present sixth-form chemists, as I would like to, with the two *Students' Books* alone would (assuming that the *Students' Book 2* will be the same price as *Students' Book 1*) cost about £250; which is two-thirds of my normal annual departmental allocation for all books, chemicals, and everyday apparatus. And the binding and appearance of these books do not make me confident of their ability to resist constant usage even for just two years.

Only two of the project team responsible for this course remain as full-time teachers; and rather too many of the teachers and former teachers in the team came from well-favoured independent and direct-grant schools. The team's collective view of what is at present possible for the average teacher in the average school with average facilities and technical help and on an average budget may be too rosy. One eventual result, however, could be the establishment of a norm for the provision of resources for chemistry teaching which determined teachers can quote when arguing with unhelpful local education authorities.

All teachers will recognize among their pupils the existence of two extreme types: the clever idler and the apparently slow-witted but conscientious slogger. The one redeeming feature of the old syllabuses was that their factual and descriptive content gave scope for the hard worker to pass the eventual exam, and sometimes to pass well. From the objective point of view I am not suggesting that this feature was necessarily a good thing; but, speaking subjectively, I am all for rewarding hard work and character, and I fear that the slow but steady worker will have little luck with the more conceptually intense Nuffield-type courses. The possibility must be faced that there may be fewer A-level entrants in chemistry although these should have a better understanding of the subject.

These criticisms—if criticisms they are—are no fault of the project team. But the team can, of course, be held responsible for the uniformly high quality of the material in these books. The *Students' Book 1* is clearly written and easy to read. Each topic contains instructions for experimental work, discussion of underlying theory, passages of background reading incorporated into the text, and problems. Nuffield courses undergo exhaustive testing before publication; nonetheless, I have tried to carry out my own validation. Since the beginning of term, I have been building up ideas about ionization energies, energy levels, and so forth with my first-year sixth form. I have deliberately stuck to the Nuffield text on these topics. Impressions on both sides are excellent. The *Teachers' Guide* is a necessity, particularly for those teachers to whom much of the material (and some of the chemistry!) will be new. Each section of each topic is set out thus: objective, timing (somewhat optimistic in places), suggested treatment, supporting material and suggestions for homework, and answers to problems in the *Students' Book*. There are lists of materials and apparatus required for the experimental work. Much extra theory is included for the benefit of the teacher. *Ion Exchange* is one of the five *Special Studies*, one of which has to be selected by each student as part of his course. The book makes an excellent introduction to the subject, with particular and welcome emphasis on the applications of ion exchange in industry, medicine, and agriculture.

In his foreword to each book Brian Young writes that "the need is for courses which are satisfying and intellectually exciting in themselves—not for courses which are simply passports to further study". In the hands of capable teachers and reasonably well-motivated pupils, these books should certainly increase the volume of satisfaction and excitement associated with any A-level course in chemistry.

MARTYN BERRY

INTEGRATED SOCIAL SCIENCE

Understanding Society

Readings in the Social Sciences. Edited by the Social Science Foundation Course Team, the Open University. Pp. xx+712. (Macmillan: London, October 1970. Published for the Open University.) 50*s* boards; 20*s* paper.

IT has generally been an American rather than a British tradition to produce volumes of readings in the social sciences for undergraduates. The British tradition has been for the undergraduates to look up the relevant articles for themselves in the library and to be guided by their tutors, but in the American system of mass lecturing, with comparatively heavy reading loads for the undergraduates, the practice of issuing prepared volumes of readings has been usual. The American practice has also been useful to people who teach in English universities and colleges, because, in fact, it seems that only a minority of students actually do the looking up for themselves which they are expected and intended to do.

The Open University, dealing with part time students scattered over the whole of the country, usually only with access to the local public libraries, manifestly cannot expect people to browse among the back runs of learned journals, and they have produced a volume of readings for the Social Sciences Foundation Course. This volume of readings is based on two principles. The first is that it contains, on the whole, the results of original thought or research by fairly distinguished people in a number of fields, including social anthropology, geography, economics and sociology. The second is that this is intended to be seen by the student and by his tutors as an integrated approach to the study of the problems of society.

The individual articles in this volume are sometimes excerpts from books, sometimes articles complete in themselves and obviously some disciplines are better represented than others. Nevertheless, it is a well chosen and interesting series of essays which suggests to the reader and especially, one hopes, to the careful student, how specialists in a particular subject set about their work. Integrated courses in the social sciences have become popular in recent years, principally because of the holistic philosophy that some teachers have had, that, because man and mankind are one, the study of mankind also needs to be unified. There is an obvious fallacy here, for any disciplined approach to the study of mankind or of nature must entail dealing with small pieces of things in detail as well as larger and more embracing general philosophies. The result of a great many integrated courses seems to

be a smattering of knowledge in a great many fields and a tendency to dismiss with obloquy those disciplines which are particularly difficult to study. It is, I think, not an accident that the natural sciences have always been extremely cautious in choosing this approach to their own disciplines.

The great lack in this volume is of any mathematical and statistical approach to the study of society. The great advances in economics have come about largely through the applications of mathematical techniques, and this is equally true of other disciplines. There is in this volume a lack of model building illustrated as a technique in the social sciences, and an implicit dismissal of the understanding of statistical procedures. In this sense the bias of the volume is probably understandable but may be unfortunate. Nevertheless, with this one grave lack, the volume may be commended as an interesting guide for the interested and ignorant student who nevertheless wishes to undertake some work which is both stimulating and fairly rigorous. It resembles the great works of H. G. Wells and his collaborators on popularizing the social and physical sciences and mathematics, and for that reason it has a splendidly nostalgic flavour.

JOHN VAIZEY

SYMMETRY AND PARTICLES

Unitary Symmetry and Elementary Particles

By D. B. Lichtenberg. Pp. xiii + 239. (Academic: New York and London, May 1970.) 121*s*.

THIS book is definitely mathematical rather than physical, and possesses both the strengths and weaknesses of such an approach. On the one hand, the mathematics is fully (and relatively simply) explained, starting from the fundamental axioms concerning groups. Group representations in vector spaces are considered, first for Lie groups in general, then for SU(n) and finally for SU(3). The eight-fold way itself first appears on page 152, and departs on page 183. (SU(6) and quarks occupy the rest of the book.)

On the other hand, there is a kind of mismatch between this mathematics and the physics it is supposed to describe. For example, the machinery for reducing an arbitrary product representation in SU(3) is irrelevant, because only singlets, octets and decuplets actually exist. Again, SU(6) does not actually apply to any physical object (except for SU(6)w which is not treated). And, of course, quarks, whether or not they exist, can hardly have the simple dynamics required in many applications of the quark model.

This mismatch is, of course, partly a feature of the subject, for which the author is not entirely responsible. The book is well written and may be useful as a reference book; but at the price it is hardly a good buy for the individual.

D. H. LYTH

PHYSICS OF COMMUNICATION

The Physics of Transmission Lines at High and Very High Frequencies

Vol. 1: Primary and Secondary Parameters, Travelling Waves, Pulses. By P. Grivet. Pp. xiii + 451. (Academic: London and New York, June 1970.) 150*s*.

A COMMUNICATION transmission line is often regarded as an important element of a communication system but a rather dull subject for a 450-page book. Professor Grivet destroys this view by providing an excellent treatment of the physical principles of the subject within a frequency band which embraces telephone lines and microstrip. The text is based on lectures delivered by the author in Paris and Orsay and, as such, is unlikely to fit the structure of a physics or electrical engineering degree course in Britain. Nevertheless, any lecturer planning a course in this field would do well to consult this book.

A successful attempt has been made to harmonize the field theory and circuit theory approaches to the subject. The calculation of capacitance, inductance and resistance is considered in some detail and 60 pages are devoted to methods involving the complex plane. The chapter on the quasi monochromatic wave includes a clear explanation of group velocity and the adequate discussion of delay equalization is typical of the extent to which the author has used practical systems to illustrate the theory. In this respect the text will also appeal to those telephone engineers who seek a perspective view of their subject, for the author has included an adequate historical background to the development of current practice. Pulsed operation of lines is discussed in some detail but the chief omission is an extensive treatment of matching techniques. This in part reflects a cut-off in the treatment at VHF.

The translation by Dr P. W. Hawkes seems uniformly excellent and the author's clear style of expression has been captured. The text can be unreservedly recommended and I await with interest further volumes in the series.

P. J. B. CLARRICOATS

AURORAL SUBSTORMS

Polar and Magnetospheric Substorms

By Suyn-Ichi Akasofu. (Astrophysics and Space Science Library.) Pp. xviii + 280. (Reidel: Dordrecht, 1968.) 55 florins.

THIS is an excellent reference book for research workers in auroral and magnetospheric physics, and good general reading for others interested in knowing of recent progress in the study of that fascinating and beautiful natural phenomenon, the aurora.

Over a hundred years ago it was realized that there was a connexion between strong auroral displays observed occasionally from well inhabited parts of the globe, "magnetic storms" (which occur on a world-wide scale on such occasions) and large sunspot groups and flares on the Sun's surface. It is now known that around the auroral oval (a narrow belt a few degrees of latitude wide near 70° magnetic latitude, with its centre displaced about 3° from the Earth's dipole pole toward the dark hemisphere) auroral displays occur practically every night, but the magnetic disturbances accompanying them are localized (hence the term polar substorm). Polar substorms occur with greatest frequency and intensity during world-wide magnetic disturbances.

Professor Akasofu pioneered the analysis of hundreds of all sky camera photographs of the aurora taken from many different places during the International Geophysical Year, and built up a large-scale picture of the sequence of events (as observed in the visible light portion of the electromagnetic spectrum) which occur during a polar substorm around the auroral oval. He showed that auroral substorms usually last an hour or so and occur every few hours, with maximum activity centred at those stations close to local midnight. He showed that different types of activity, and the direction of motion of the auroral forms observed at any one station, depend both on the local time of observation and on the phase of the substorm. It is now recognized that many other ionospheric and magnetospheric phenomena exhibit characteristic behaviour dependent on local time in and near the auroral oval or on magnetic field lines leading into it during polar substorms.

In his book Professor Akasofu summarizes and gives detailed references to observations both from the ground and from rockets and satellites of the sequence of events

which occurs during polar substorms in various wavelength ranges of the electromagnetic spectrum, and with trapped and precipitating charged particles, taking a chapter to describe each different group of experimental observations. In his last chapter he gives an account of several different theories which have been advanced to explain the nature and origin of polar substorms. It is generally accepted that the substorm energy derives from the solar wind, but no theory advanced so far has produced an explanation for the way in which solar wind energy is introduced into the magnetosphere. He concludes by pointing out that the large, and as yet unsolved, problem in this field is to determine the nature and causes of the magnetospheric electric fields responsible for the polar substorms.

PAMELA ROTHWELL

UPPER ATMOSPHERES

Chemistry of the Ionosphere

By A. D. Danilov. Translated from the Russian. (Monographs in Geoscience.) Pp. xv+296. (Plenum: New York and London, 1970.) $22.50; 210*s*.

IN the past decade the development of space research techniques, coupled with the organization of world-wide cooperative studies in solar-terrestrial physics, have resulted in a vast accumulation of new detailed experimental data on the Earth's upper atmosphere. The interpretation of these data in terms of basic physical and chemical processes is a major task of current interest. This volume, in the words of the author, "is an effort to present an integrated review of information on the most important aspects of the chemistry of the upper atmosphere, covering both laboratory investigations of the pertinent chemical processes and studies for clarifying the role and rate of these processes in the atmosphere". The term "upper atmosphere" is here used to denote the height range 60 to approximately 800 km and throughout the book the emphasis is on the reactions involving charged particles. The principal topics covered include a summary of current data on atmospheric density, temperature, composition, electron and ion concentrations; elementary photochemical processes in the ionosphere; dissociative recombination, ion-molecular processes, the role of negative ions, the dissociation of oxygen and of nitrogen, reactions involving oxygen and nitrogen, reactions involving neutral and ionized hydrogen and helium atoms.

No consideration is given to the airglow, nor to certain other related aspects of the chemistry of the ionosphere such as rocket experiments on the high altitude release of chemical reagents. The justification for such omissions is that in the case of the airglow, the subject is large enough to merit a separate volume and the results of chemical releases are not discussed, because it is not considered that they have as yet added much "of importance for the study of basic problems in ionospheric chemistry".

The original Russian text was prepared in 1965, and it is recognized that in the past few years certain new theoretical and experimental studies have been published which bear on some of the problems discussed in the book. In a brief appendix the author summarizes some of the more important relevant papers published recently, and, in particular, some attention is given to the complex pattern of chemical reactions now emerging from rocket studies of the D-region.

The book is eminently readable and is provided with a very useful selected bibliography covering a total of nearly 600 references. The translation and production are both excellent and the volume will be invaluable for ionospheric workers requiring a concise, authoritative text.

W. J. G. BEYNON

Film Review

KALEIDOSCOPE OF MAN

The Body

Produced by Tony Garnett. Directed by Roy Battersby. (112 min.) At the Classic, Piccadilly, London.

IN its way, the film *The Body*, produced by Tony Garnett and directed by Roy Battersby, should be a courageous and major undertaking. In recent years very few producers have been able to make for the commercial cinema feature-length, semi-documentary films which do not use name stars. Unfortunately, compared with our human frames whose working it depicts, *The Body* is slightly less than the sum of its parts, although it does make a compelling, if contentious, 1 hour 40 minutes of cinema.

The film, at least those parts of it dealing with the body corporeal, is loosely based with credit on Mr Anthony Smith's recently published and well received book. However, parts of the film deal with the body politic and are merely tangentially polemic comments devoted to the thesis that we are all brothers under the skin. These parts of the film are loosely based without credit on books by Marcuse, Fanon, Reich, Laing, Marx, Engels and Trotsky. In these sections the film is tediously obvious and unsatisfying.

The hero of the film is indeed the human body in all its workings. Mr Tony Imi's outstanding and magnificent photography illustrates and explores brilliantly and sensuously the nature of our physical world. Under his lens, nipples look like volcanic peaks; the curves of the abdomen take on the appearance of a countryside; the hairs of the hand become like a forest of trees. The body beautiful, the body loving, the body eating, the body excreting, the body moving and the body working. To support all these functions stunning X-ray, endoscopy and schlieren techniques are triumphantly employed.

As such there is no story, only a collection of sequences whose internal order is difficult to divine. These excursions into the corpus mysterium are generated on a wave of neo-paganism, which in turn is carefully nurtured and based in a neo-Eden. Here bodies beautiful, leavened with bodies decrepit, discard clothing in carefully contrived and lengthily considered innocence. The attitudes in this new Eden of these noble (strictly working-class, jam butty) savages can be described as a cross between the Esalen institutes of California and a progressive Workers' Educational Association gymnastics class. Within this studio paradise our lads and lasses indulge in the innocent and not so innocent tactile exploration of each other, leading from sequence to sequence and situation to situation.

Mens sana in corpore sano. Don't you believe it! Every Eden has its serpent! In this case it is the exploitation of our wonderful bodies as wage slaves or the smothering of this magnificent, moving, loving, laughing (not to mention breathing, copulating, energy balancing) human apparatus, in the pollution engendered by our ravishing of our environment.

Thus the opportunity is provided for Miss Vanessa Redgrave and Mr Adrian Mitchell to bare their souls on the soundtrack while others bare their breasts for the picture. They glumly remind us of the doom about to overtake our fragile remains or the dreariness of our production line existence.

Within this framework are some outstanding sequences:

- The clever graphic demonstration of the tons of food eaten by the average Western man in his lifetime, contrasted with the average Indian peasant's consumption.
- A moving and wonderful birth sequence. The midwife, like Juliette's nurse, fussing over mother and baby with a humanity that shares the event with the world, trans-

cending the voyeurism implicit in eavesdropping on such an intimate moment in a married couple's life.

- A funny, brilliant pastiche of a baby crawling over glass. Every hand print and foot print lights up as it walks—it sounds simple, but the camera work and lighting make it a magical moment.
- A magnificent introductory tracking shot of bodies (some 98 of them I believe) ranging from the very young to the aged and infirm.
- Richard Gregory's optical illusions are beautifully demonstrated, as well as some of J. Tanner's film on growth.

There are also some boring sequences. A demonstration of foreplay (some in schlieren no less!) and sexual intercourse is as lengthily tedious as it is unnecessary. Whilst scrupulously satisfying edicts of the British Board of Film Censors, it seems designed more to titillate than reveal. It seems to be included, along with other sequences, to meet some film distributor's estimate of the audience's taste rather than being concerned with the needs and integrity of the subject.

This is, alas, the essence of the film. Too often while pretending to be "vulgar" in the original and honourable sense of the word, the element of voyeurism implicit in the producing of today's "flesh" movies makes the film "vulgar" with all that the modern meaning implies. It thus mars what otherwise might have been an outstanding film.

"Birth, copulation and death,
I should be bored,
I should be bored."

So far as this film is concerned, T. S. Eliot just misses hitting the nail on the head, but he is not far off the mark.

AUBREY SINGER

Correspondence

Soviet Restrictions

SIR,—I am glad to see from Jukes's letter (*Nature*, **228**, 589; 1970) that I am not the only one who thinks the letter from Bikerman (*Nature*, **228**, 297; 1970) extraordinary. To compare his own failure to obtain a travel grant with the trials of Medvedev is an insult to a very courageous man. No one is presumably preventing Bikerman from leaving the USA, whereas, to judge from Medvedev's testimony, the attitude of the Soviet authorities borders on the psychotic. On balance, it is Bikerman's letter, not Medvedev's book, which is "subtle communist propaganda".

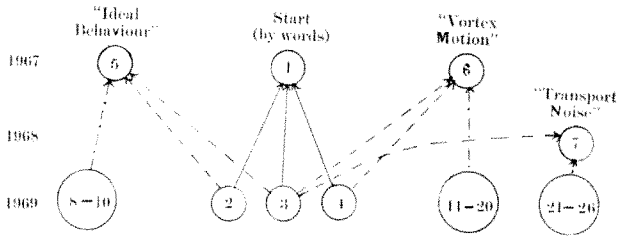
Cahn's subsequent point (*Nature*, **228**, 485; 1970) about the non-arrival of Russian speakers at meetings is unfortunately only too common. He might have added that, when they do turn up, they have often been allocated barely two pieces of hard currency to rub together. The consequences of this can be extremely embarrassing.

Yours faithfully,

G. B. ANSELL

Department of Pharmacology,
The Medical School,
Birmingham B15 2TJ.

Science Citation Index



SIR,—Following E. Garfield's article[1] about heavily cited authors, several apparent shortcomings of the *Science Citation Index* (*SCI*) have been pointed out[2–4]. I could list many other reasons why the *SCI* apparently should not work, and why the "most cited author" list may be misleading.

The reason why the *SCI* does work and the list is valuable becomes clear if we talk about probabilities rather than certainties. Thorough investigations[5] of citation practices show that various apparent shortcomings do not normally affect the system; they are low probability events or possibilities—in contrast to the high probability that a well cited article reflects a beneficial progressive impact.

Hopefully, the system will be used with discrimination, unlike the usage described by Croom[4]. Hopefully also, the assessment of an author by citation counts will be qualified by a consideration of the activity in his subject area, nature of the research front, and so forth—in conjunction with any other facts or opinions that may assist in the assessment. I think we may assume that Garfield's remark: ". . . it is up to the scientific community to prevent abuse of the *SCI* . . ." means that the *SCI*, author lists and such like, should be applied with reasonable intelligence.

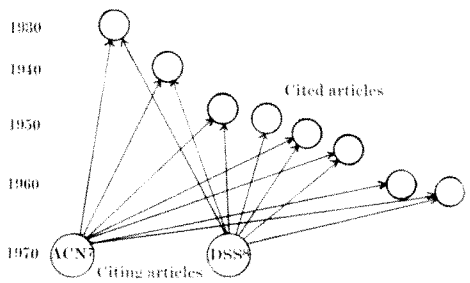
A reader of the top of the league table will doubtless reflect on the nature of the author's impact—whether it be inventive, original, interpretive or methodological. Moreover, if our author is cited consistently, year after year, perhaps long after he published, it may be concluded that his impact endures.

The set of subjects symbolized in the references of an article is usually associated with the subjects, concepts, methods, apparatus and so on, described in the text (there are also occasional excesses of undeserved self-citing and bibliographic mutual back-scratching).

A, Locate starting article by words in the *Permuterm Index*: 1.
B, Enter *Citation Index* to locate citing articles. Examine references keyed to specific aspects of the subject in the text: →, 2, 3, 4.
C, Select references symbolizing those aspects: — — →, 5, 6, 7.
D, Enter the *Citation Index* to locate articles, — · → 8–10, 11–20, 21–26, which cite the "subjects" 5, 6, 7 respectively.

Fig. 1. Identification of subject aspects—"The physics of superconductors".

Fig. 1 illustrates the citation connexions between articles about "The physics of super-conductors". Articles 5, 6 and 7 were rather easily identified with certain aspects of the subject when using the *SCI* without subject expertise. Articles citing them relate to similar aspects.



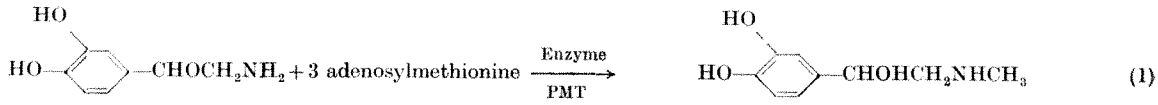


Fig. 2. Similarity of articles indicated by "bibliographic coupling". Two articles, each containing eight references, have six of them in common.

(1)

Norepinephrine (noradrenaline) Epinephrine (adrenaline)

An artefact called "bibliographic coupling"[6] was used when considering this subject. An extreme example of it recently occurred in *Nature*, when two articles[7,8] (published independently) contained virtually the same set of references (Fig. 2). A study of such diagrams helps to identify subject similarity, particularly when titles are inexplicit, and the articles appear in journals with apparently quite different disciplinary coverage (quite a common occurrence).

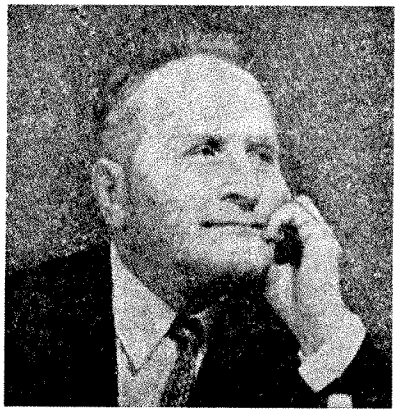
Quite complex concepts may be conveniently symbolized by a reference. Thus the enzyme assay shown in equation (1) is symbolized by:

Saelens, J. K., *et al.*, *Biochem. Pharm.*, **16**, 1043 (1967)

which leads to:

Nikodije, B., *et al.*, *Biochem. Pharm.*, **18**, 1577 (1969). "Catechol-o-methyltransferase 1. An enzymatic assay for cardiac norepinephrine" (a 1969 article which cites Saelens).

Because only 0·005 per cent of authors are in the exalted category mentioned by Garfield, and because the outcome of the average *SCI* search is usually based on the works of the remaining 99·995 per cent, one look-up in the *SCI* usually locates a small number of relevant articles, together with an even smaller amount of "noise"[9]. This is one of the main virtues of the system.



Yours faithfully,

A. E. CAWKELL

Obituaries

Professor David Al'bertovich Frank-Kamenetskii

ON July 2, 1970, Professor David Al'bertovich Frank-Kamenetskii, one of the leading scientists and science journalists of the Soviet Union, died suddenly in his fifty-ninth year.

David Frank-Kamenetskii was born in Vil'nyus in 1910, the son of a chemical engineer who later became a professor at the University of Irkutsk. He graduated in the department of non-ferrous metallurgy of the Tomsk Technological Institute and after working for a period in a factory and a period as a teacher in a technical college he was invited by Academician N. N. Semenov to go to the Institute of Chemical Physics of the Academy of Sciences of the USSR in Leningrad, where in 1938 he presented his thesis for the degree of candidate of chemical sciences. In 1943 he became a doctor of physical and mathematical sciences, and became head of the department of technical chemistry in Gor'kii State University. From 1956 onwards, he worked in the Kurchatov Institute of Atomic Energy and at the same time founded and directed the Department of Plasma Physics in the Moscow Institute of Physics and Technology.

Frank-Kamenetskii was known for his basic research in a number of fields, including the theory of combustion and chemical kinetics, exothermic reactions, astrophysics and plasma physics; in the last field he introduced the concept of magnetosonic resonance. His works include *Diffusion and Heat-Transfer in Chemical Kinetics*, *Oxidation of Nitrogen in Combustion and Explosions*, *Physical Processes within Stars* and also a number of popular works on physics and astrophysics. During recent years he was deputy chief editor of the popular science magazine *Priroda*.

For his own research work, and for his achievements in the popularization of science, he was awarded a number of prizes and honours, including the Order of Lenin, the Order of the Red Banner of Labour and three State Prizes of the Soviet Union.

Academician S. S. Medvedev

THE death occurred on August 13, 1970, of Academician Sergei Sergeevich Medvedev, one of the most renowned Russian specialists in the physics and chemistry of high molecular compounds. He was in his eightieth year.

Sergei Medvedev was born in Moscow in 1891. After graduating from Moscow University in 1918, he played an active part in the organization of the Central Asian University of Tashkent and became head of the Central Chemical Laboratory of the Uzbek Council of Agriculture. In 1922 he founded the laboratory of oxidation and polymerization processes in the L. Ya. Karpov Physical Chemistry Institute in Moscow, holding the post of head of the laboratory until the end of his life. From 1938 onwards, he was an instructor at the Moscow Institute of Fine Chemical Technology. He became a corresponding member of the Academy of Sciences of the USSR in 1938, and was elected to full membership of the Academy in 1958.

Medvedev's research dealt with many pure and applied aspects of polymerization, including the production of synthetic rubber, the effect of nuclear radiation on polymerization and the production of synthetic textiles.

He was the first to give an experimental demonstration of the presence and role of free radicals in the polymerization process, and discovered a number of laws governing the course of polymerization.

His publications include *Research on the Laws of Emulsion Polymerization* (1963) and *Obtaining Syndiotactic Polymethylmethacrylate in Water Emulsions* (1966). He was awarded a number of orders and prizes for his work, including the Stalin Prize (1946), the Order of Lenin and the Order of the Red Banner of Labour.

Announcements

University News

Dr Douglas Bond has been appointed to the chair of civil engineering in the **Queen's University of Belfast** and **Dr Adrian Roberts** has been appointed to the chair of engineering mathematics.

Professor J. H. Kellgren, director of the Rheumatism Research Centre and professor of rheumatology, has been appointed dean (part-time) of the Medical School, **University of Manchester.**

Dr H. O. Foulkes, Department of Pure Mathematics, and **Dr C. Grey Morgan,** Department of Physics, have been appointed to personal chairs in the **University College of Swansea.**

ERRATUM. In the article "Variation of the Luminescence Lifetime of a Molecule near an Interface between Differently Polarizable Dielectrics" by K.-H. Tews, O. Inacker and H. Kuhn (*Nature*, **228**, 276; 1970), on p. 277, column 1, line 11 from bottom, ref. 5 should be replaced by ref. 6; on line 2 from bottom, ref. 2 should be replaced by refs. 2 and 3. Equation (5) should read

$$f(x) = \frac{4\sin x}{x^3} + \cos x - \frac{4\cos x}{x^2} + x\left(\mathrm{Si}(x) - \frac{\pi}{2}\right)$$

ERRATUM. In the article entitled "Influence of Hydrostatic Pressure on the Reversible Polymerization of Fibrin Monomers" by D. Collen, G. Vandereycken and L. De Maeyer (*Nature*, **228**, 669; 1970), all figures referring to pressure should be read as thousands.

ERRATUM. In the article by M. Paecht-Horowitz, J. Berger and A. Katchalsky (*Nature*, **228**, 636; 1970), a sentence was unfortunately left out in the opening paragraph. The last five lines should be substituted by: ". . . starting material for primaeval biosynthesis. So far, however, only low molecular weight peptides have been obtained, both with the phosphates of amino-acids and with dicyandiamide, and such peptides would have a doubtful claim to be the precursors of contemporary biopolymers. By thermal polymerization in anhydrous conditions we have obtained larger polymers[8,9], but it is unlikely that such conditions prevailed in the prebiotic state." In addition, the title of Table 1 should be "DATA ON PEPTIDES (1)".

CORRIGENDUM. The article "Variability, Structural Glycoproteins, and Classification of Herpes Simplex Viruses" (*Nature*, **227**, 1253; 1970) was published without a final correction. Although the authors were in general agreement with the statement regarding the unsuitability of either the name herpesvirus hominis or herpes simplex, the manuscript should have noted that they were not in complete agreement with the designation of subtypes. A. J. Nahmias and W. R. Dowdle preferred to retain the type 1 and 2 designations, reasoning that the biological, clinical and epidemiological differences are sufficient to justify considering them as distinct serotypes.

British Diary

Monday, November 23

Building Linear Filters from Logic Circuits (7.30 p.m.) Mr M. H. Ackroyd, Institution of Electrical Engineers, at the University of Leicester.

Engineers in General Management Posts—the Army's Experience (5.30 p.m.) Major General R. L. Clutterbuck, Institution of Civil Engineers, at Great George Street, London SW1.

Fire Precautions in Locomotives and Rolling Stock (5.30 p.m.) Mr J. M. Jarvis, Institution of Mechanical Engineers, Railway Division, at 1 Birdcage Walk, London SW1.

Founders of Radio-Analytical Chemistry (6 p.m.) Professor R. Spence, Society for Analytical Chemistry, Radiochemical Methods Group, at the Polytechnic of the South Bank, Borough Road, London SE1.

Microwave Ultrasonic Devices (6 p.m.) Mr R. F. Humphreys, Institution of Electronic and Radio Engineers, Aerospace, Maritime and Military Systems Group, at 8–9 Bedford Square, London WC1.

The Rejection of Laplacian Physics: a Turning-Point in the History of the Physical Sciences in France (5.30 p.m.) Mr Robert Fox, British Society for the History of Science, in the Lecture Theatre of the Science Museum, Exhibition Road, London SW7.

Tuesday, November 24

Biogenesis and Chemogenesis of Recent Marine Sediments (2 p.m.) Geological Society, Marine Studies Group, at Burlington House, Piccadilly, London W1.

Distribution Research at the Electricity Council Research Centre at Capenhurst (5.45 p.m.) Mr G. Ratcliff, Institution of Electrical Engineers, at the Renold Building, UMIST, Manchester.

High Cereal Yields (5.15 p.m.) Sir Joseph Hutchinson, FRS, Royal Society of Arts, Commonwealth Section, at John Adam Street, Adelphi, London WC2.

Offshore Drilling Rigs (two-day symposium) Royal Institution of Naval Architects, in the Weir Lecture Hall, 10 Upper Belgrave Street, London SW1.

Particle Size Analysis of Unusual Materials (6.30 p.m.) Mr J. E. C. Harris, Mr H. J. Scullion and Professor H. Heywood, Society for Analytical Chemistry, Particle Size Analysis Group, in the Physics Lecture Theatre, Imperial College, Prince Consort Road, London SW7.

Porphyria and Photosensitivity (5.30 p.m.) Dr I. A. Magnus, University of London, at the Institute of Child Health, 30 Guilford Street, London WC1. (Tenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

The Design and Construction of Butterworth Wharves, Malaysia (5.30 p.m.) Mr J. W. T. Tapp, Mr A. J. B. Dixon and Mr A. C. Carpenter, Institution of Civil Engineers, at Great George Street, London SW1.

The Identification of Rogue Materials in Reactor Construction (4.30 p.m., discussion) Institution of Mechanical Engineers, Nuclear Energy and Steam Plant Groups, at 1 Birdcage Walk, London SW1.

The Relationship of Styles of Management to Productivity (5.30 p.m.) Professor Richard Beckhard, Institution of Electrical Engineers, at Savoy Place, London WC2.

Wednesday, November 25

Chromatographic Techniques in Toxicology (2.30 p.m.) Society for Analytical Chemistry, Chromatography and Electrophoresis Group, at Chelsea College of Science and Technology, Manresa Road, London SW3.

Carbon Fibres for Engineering Applications (6 p.m.) Mr L. N. Phillips, Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1. (Thomas Hawksley Lecture.)

Continuing Education for Electronic Engineers (7.30 p.m.) Mr K. G. Stephens, Institution of Electrical Engineers, at the Star and Garter Hotel, Dorking, Surrey.

Cyclic Sedimentation and Faunal Response in the Cretaceous Basin of Western Interior North America (5 p.m.) Dr Erle G. Kauffman, Palaeontological Association, at the Geological Society of London, Burlington House, Piccadilly, London W1.

Early Timber Bell Towers (5.30 p.m.) Mr K. W. E. Gravett, Royal Institution, Library Circle, at 21 Albemarle Street, London W1.

Electronic Techniques in Archaeology (7.30 p.m.) Mr M. J. Aitken, Institution of Electrical Engineers, at Sumpner Building, University of Aston, Birmingham. (Silvanus P. Thompson Lecture.)

Famous Experiments in the Royal Institution (5.30 p.m.) Sir Lawrence Bragg, CH, FRS, Royal Institution, at 21 Albemarle Street, London W1. (Lecture for Fourth Form pupils from Schools in London and the Home Counties. To be repeated on November 26, December 1 and 2.)

Laminar Flow Devices and HEPA Filters (2.30 p.m., symposium), in the Mechanical Engineering Department, Imperial College, London SW7.

Progress in Taint-Free Packaging (6.15 p.m., symposium) Society of Chemical Industry, Food Group, jointly with PIRA, at the Zoological Society, Regents Park, London NW1.

Psychiatry, Science and Non-Science (5.30 p.m.) Dr E. T. O. Slater, University of London, at the Institute of Psychiatry, De Crespigny Park, London SE5.

Recent Advances in Isoenzymes (2 p.m.) Professor J. H. Wilkinson, University of London, at the Royal Postgraduate Medical School, Du Cane Road, London W12.

Sir George Cayley "On Aerial Navigation", 1809-1810 (1 p.m.) Mr Charles H. Ginns-Smith, Royal Institution, History of Science Discussion Group, at 21 Albemarle Street, London W1.

Sleep and Dreams (7.15 p.m.) Mr C. Evand, Institution of Electrical Engineers, at the College of Technology and Art, High Wycombe, Bucks.

Thomas Huxley Manuscripts (6 p.m.) Mrs Jeanne Pingree, Society for the Bibliography of Natural History, in Conference Suite 3, College Block Imperial College, London SW7.

Thursday, November 26

Applications of Lasers (2.15 p.m.) Professor E. D. R. Shearman, Institution of Electrical Engineers, at Mander College, Bedford.

Applications of On-line Analytical Techniques to Process Control (10 a.m. colloquium) Institution of Electrical Engineers, in association with the Institute of Measurement and Control and the Institution of Mechanical Engineers, at the IEE, Savoy Place, London WC2.

Diophantine Equations (5.30 p.m.) Dr G. L. Watson, University of London, in the Engineering Theatre, University College London, Malet Place, London WC1. (Inaugural Lecture.)

Dynamic Characteristics of Silicon Controlled Rectifiers (7 p.m.) Mr R. G. Dancy, Institution of Electronic and Radio Engineers, at Medway College of Technology, Chatham, Kent.

Flow Measurement in Fan Testing (6 p.m. discussion) Institution of Mechanical Engineers, Fluid Plant and Machinery Group, at 1 Birdcage Walk, London SW1.

IgE and Hypersensitivity in Man (5.30 p.m.) Dr D. R. Stanworth, University of London, at the Institute of Child Health, 30 Guilford Street, London WC1. (Eleventh of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Modern Trends in Pollution Control (4 p.m.) Dr G. Mattock, Society for Analytical Chemistry and the Andersonian Chemical Society, in the Thomas Graham Building, University of Strathclyde, Cathedral Street, Glasgow C1.

Press Coverage of Pharmacy's History (7 p.m.) Mr O. Waller, Pharmaceutical Society of Great Britain, and the British Society for the History of Pharmacy, at 17 Bloomsbury Square, London WC1.

Putting Roland Into the Computer (1.20 p.m.) Professor W. Woledge, University of London, at University College London, Gower Street, London WC1.

New Horizons in Meteorological Instrumentation (6.30 p.m.) Dr H. T. Ball, Institution of Electronic and Radio Engineers, jointly with IEE, at the University Engineering Laboratories, Trumpington Street, Cambridge.

The Control of Fertilizer Granulation Plants (2.30 p.m.) Dr J. A. Bland, Dr J. L. Hawksley and Mr W. J. Perkins, Fertilizer Society, in the Lecture Hall of the Geological Society, Burlington House, Piccadilly, London W1.

The Social Impact of Modern Biology (three-day meeting) British Society for Social Responsibility in Science, at Friends House, Euston Road, London NW1.

Friday, November 27

Industrial Training (7.15 p.m.) Mr H. R. Peel, Oil and Colour Chemists' Association, at the Royal Hotel, Bristol.

Laser-Flash Photolysis (1 p.m.) Dr M. West, Royal Institution, Photochemistry Discussion Group, at 21 Albemarle Street, London W1.

Perspectives on Pesticides (2.15 p.m.) British Pest Control Association, at the National Liberal Club, Whitehall Place, London SW1.

Some Diseases of the Rat (symposium) Laboratory Animal Science Association, at the Zoological Society of London, Zoological Gardens, Regent's Park, London NW1.

The Life of the Common Porpoise (9 p.m.) Professor R. J. Harrison, Royal Institution, at 21 Albemarle Street, London W1.

Vitamin D Metabolism in Man (4 p.m.) Professor S. W. Stanbury, University of London, at the Royal Postgraduate Medical School, Du Cane Road, London W12.

Monday, November 30

Organization of Pollution Studies in Hydrology (4.30 p.m., informal discussion) Institution of Civil Engineers, Hydrological Group, at Great George Street, London SW1.

The Exploration, Protection and Management of the World Ocean—a Challenge for the 1970's (5.30 p.m.) Dr S. J. Holt, University of London, at University College London, Gower Street, London WC1.

The Possibility of Predicting the Life of Hydraulic Equipment Under Operating Conditions (4.15 p.m., discussion) Institution of Mechanical Engineers, Fluid Plant and Machinery Group, at 1 Birdcage Walk, London SW1.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire..... **£14 0 0** each

United States of America.....(by air freight)..... **$48** each

Canada.....(by air freight)..... **$52** each

Elsewhere overseas by surface mail..... **£14 0 0** each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata*. (Minimum three months.)

DECEMBER 5, 1970

Communications Without Talk

THE precipitate dismissal of Lord Hall, the chairman of the Post Office Corporation, just a week ago is probably one of the best things to have happened to the British telecommunications industry since the Post Office was made a public corporation just over a year ago. Lord Hall, to be sure, has been unlucky in having had to take the brunt of the inevitable strains that there would be in turning the British Post Office from a government department into a public corporation. To expect that somebody qualified in the comparatively abstract concepts of medicine, politics and the law should turn out to be well suited as the head of a commerical enterprise seeking to find its feet in unfamiliar terrain was probably over-optimistic of Mr Harold Wilson and the other members of the Labour Government. In the circumstances, it is hardly a surprise that Mr Christopher Chataway, the new Minister of Posts and Telecommunications, was able to beat off the censure motion by the Opposition in the House of Commons earlier this week. Unfortunately, nothing said in this predictably acrimonious debate has helped to clarify the problems with which the Post Office Corporation must contend, most of which are painfully apparent in the first report to be published under the new arrangements (HMSO, £1 10*s*).

The Post Office is one of the largest enterprises in Britain. Its income is something like three per cent of the Gross National Product and is growing more quickly than that of any barely comparable enterprises at more than ten per cent a year. It is in the ordinary sense a conglomerate, with a responsibility not merely for delivering the mails and operating the telephone service but also for a bank (the giro system) and for a computer bureau (the National Data Processing Service). The new report says that the objective of the reorganization carried out a year ago was to allow it the more efficiently to meet the objectives of providing an efficient service to potential users and an economic return on capital employed, but the complacent way in which the report says that the corporation was pointing in the right direction—"the influences of change and sharpened commercial awareness had been gathering momentum", for example—is at least one reason why confidence in Lord Hall's capacity to continue as chairman must have been shaken. Even if an annual report should avoid washing dirty linen in public, it might be expected not to affirm the opposite of the truth. And the plain fact, clearly revealed by the reports of the auditors accompanying the first report, is that the Post Office Corporation is still in a thorough muddle by commercial standards. Briefly, the auditors say that the Post Office accounts are kept in such a way that assertions about the value of assets cannot be verified, that stocks of equipment cannot be checked against the records, that debtors' accounts are unverifiable and that the method of recording balances of the giro customers does not adequately distinguish between the transfers of money from one post office to another and from particular post offices to customers. Plainly there is a long way to go before Lord Hall's establishment can look its commercial competitors, let alone its customers, in the face.

Good accounting or the lack of it is, however, not the most serious of the issues raised by the publication of the new report. The most serious charge against the British Post Office in the past ten years, still largely valid, is that the organization as a whole has done much less than it should have done to exploit the technology of the seventies. In the latest report, there is some cheerful talk about the rate at which would-be telephone subscribers are being supplied with telephones, but there is very little in this over-glossy document to suggest that the Post Office Corporation is really based on "a highly innovating, business-oriented technology". For example, the report has nothing to say about the potential involvement of the Post Office Corporation in cable television, but its defenders in the House of Commons and particularly the ex-Minister of Posts and Telecommunications, Mr John Stonehouse, are anxious that the right to deal with matters like this should not pass to other organizations. In a breathless chapter on "technology", the new report talks of an experiment planned for 1973 in which millimetre waves will carry 300,000 telephone conversations along a copper tube spanning 20 miles of East Anglia without acknowledging that similar experiments are already well under way elsewhere. And there is no sense that the new corporation, stripped of what were supposed to be the inhibitions of the civil service, would feel free to keep itself out of financial trouble with the government by devising and then selling things which potential customers would enjoy using. The Post Office may have ceased to be a government department, but it is a long way from pretending to be even a non-profitmaking commercial enterprise.

What is to be done? On the face of things, even the present Post Office Corporation is in need of splitting up, partly because of the internal inconsistencies in its structure and partly because the monopoly with which it thinks it is blessed is frequently an inhibition and not an incentive. Thus, in the present circumstances, when it is increasingly difficult to make a profit on the collection and delivery of mail, it is only understandable that the Post Office should find it increasingly hard to decide what must be done. Should all postal charges be increased by close on 50 per cent? Or has the time come to make some more subtle variation of the pricing

structure ? In particular, now that the Post Office's own interest in telephones has diminished the force of the old Victorian argument in favour of a uniform postage rate that rural citizens should be dealt with as those in towns, there is, for example, room for considering the basis on which uniform postal charges are imposed. This certainly is what any commercial organization would do. The chances are, moreover, that such a radical reappraisal of the principles of the Post Office's operations would lead not to greater costs but to greater efficiency. In exactly the same way, without crabbing the corporation's freedom to engage in banking or data processing, there is a case for thinking that enterprises like these could be and should be established gradually, by competing first for the cream lying free in the market and only afterwards hoping to set up the nationally integrated system on which political ideologists (and a good many civil servants) dote. All this follows from what is called, in the business schools, management science.

The Post Office Corporation is also a technological anachronism. One of the puzzles of the new annual report is that research and development expenditure, at just over £13 million in the year finishing on March 31, can be as small a proportion of the total capital expenditure. To be sure, there has been a welcome increase (of 43 per cent) over the year, chiefly on account of exchange equipment, where the Post Office is plainly seeking to make up for some of its misfortunes of the past few years. It is also true that a good deal of the research carried out in telecommunications is placed with commerical suppliers and charged for in the equipment eventually supplied. At the same time, however, it seems likely that the money being spent on research and development is too little to meet the needs of the late seventies and the eighties.

New Ways with the Moon

THE success with which the Soviet Union last week dispatched a vehicle on wheels to the surface of the Moon should be an occasion for reconsidering the ways in which the Soviet Union, the United States and several other nations might usefully collaborate in the exploration of the Solar System. At no time since President Kennedy pinned the reputation of the United States to a successful landing on the Moon within a decade have circumstances been so appropriate for serious exploration of ways in which some form of international collaboration might be brought about. For if there has ever been a race to the Moon, by now it must be clear that the race is over. The United States, to be sure, has achieved its expressed objective and has already turned its attention from the further exploration of the Moon to more ambitious schemes such as that for building a launching rocket which can be used time and time again for servicing laboratories. But who knows whether the Soviet Union had ever intended to participate in the supposed race to the Moon ? It would be entirely consistent with what the Russians have always said about the importance of sending instruments and not people on these journeys to regard their latest exploit as the attainment of their objective. There is certainly a good chance that the technique that has succeeded on the Moon may now be applied elsewhere more easily than can be the American Apollo system, so that what the Russians may have lost in glamour they may have gained in long-term benefit. Certainly their method has been cheaper. But in the United States as well as in the Soviet Union, this is evidently a time for asking what comes next.

In the United States, this question is inextricably bound up with doubts about the immediate future of the National Aeronautics and Space Administration. Dr Thomas Paine resigned two months ago but his successor is still not appointed. Worse still, the passage of close on a year since NASA committed itself to the space shuttle as the next objective of importance has not engendered confidence in the value of this proposal. There is a serious danger that the shuttle, like many earlier aircraft projects, will turn out to be disappointing in performance but much more expensive even than its supporters now confess. Certainly the decision to develop the shuttle, if confirmed by the Nixon Administration's next budget proposals due in February, will dangerously concentrate NASA's new development in space on a single project that must inevitably mean that resources cannot easily be spared for other ventures. Most probably, this simple truth is now as painfully evident inside the Administration as it is to outsiders. May it not then be that the time has come for a radical reappraisal of the programme as a whole ? And may not international collaboration be a valuable alternative to present plans ?

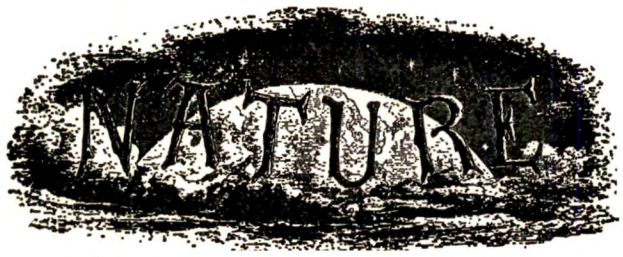
Dr Thomas Paine, the retired administrator, has a creditable record in this field. Especially in the past two years, he has consistently argued that expensive schemes for space research and development may be most valuable as stimulants of international collaboration. From time to time, he has chided the Soviet Union for dilatoriness in carrying out the Russian part in minor agreements for collaboration. In the past few months, there has been welcome progress in the setting up of talks on matters such as the design of universal couplings for spacecraft manufactured in different countries—this may not be an important problem but it is at least a useful one to start with. And both the Soviet Union and the United States have been ready in the past few months to collaborate with other nations—both the American and the Russian experiments on the surface of the Moon have, for example, provided opportunities for people elsewhere (and the French seem to have been the quickest off the mark) to obtain laser reflexions from the Moon.

By now, enough is known of the pitfalls of international collaboration to know that the simplest kinds of collaboration are also often the least useful. The European Launcher Development Organization (ELDO) is a telling example of how not to let the wish to collaborate become the father of half-baked thoughts. Where the prestige of two great powers is involved, there are evidently risks that collaboration may become simply a means of attempting tasks that seem unnecessary to the two nations separately. Everybody knows, however, that the past few years have seen both the United States and the Soviet Union attempting exploits which are hard to justify except in terms of prestige or bravado. By comparison, the international collaboration which may now grow up should be designed so as to avoid earlier and current excesses. In particular, whatever some European governments may think, the development of the space shuttle in the United States is an unsuitable subject for collaboration because it is unnecessary. And to begin with, the need for mounting experiments with diverse national origins in the same spacecraft is much less urgent than the need somehow to coordinate forward plans in such a way as to ensure that the fullest use is made of the available resources.

Geophysics Teaching in Disrepute

SUCCESS in research is as much a matter of asking the right questions as getting the right answers. It is a pity, then, that the authors of the Royal Society report on British postgraduate training in the solid earth sciences (*Postgraduate Training in the United Kingdom 5. Solid Earth Sciences*. The Royal Society, November 1970) should have failed to apply this familiar principle to the investigations which have taken them all of four years to complete. For the kindest thing that can be said about the report is that its existence at least acknowledges the subject to be worth study. And, to be sure, it recognizes in a hand-waving way a few of the problems facing the education of earth scientists—most important, the thorny question of the proliferation and continued existence of small ineffective geology departments scattered throughout the British university system. But otherwise it is a missed opportunity.

The basis of the report is the replies to a questionnaire sent to all university departments of geology and geophysics, only thirty of which responded in full. The limited scope of the investigation can be gauged from the selection of the questions asked: what qualifications do you require prospective PhD students to possess? Are there regular colloquia or seminars for PhD students? Should supervisors act as internal examiners or not? Would you favour the award of classes in the PhD degree? How frequently do candidates fail? *Et hoc genus omne*. It is perhaps only fair to acknowledge that there is a little merit in this concentration on the purely operational aspects of postgraduate earth science training if only because it has not been dealt with before. But if it is a useful exercise to ask geology departments to give information on, for example, the duration of their PhD courses, it may be presumed to be even more useful to quote the results in full rather than to present eight selected replies. For where even the total number of geology and geophysics departments is statistically small, data of this kind only make sense if they are more or less complete. The best that can be said about the technique of quoting a few choice responses is that it can be gloriously entertaining, especially as it is pretty easy to match the replies with their authors.



So what should the report have concerned itself with? The truth is, of course, that the authors have put the cart before the horse. It would have been more profitable to consider first just what present and future postgraduate training in earth sciences should achieve. A little research here would not have come amiss. What do students actually do when they have their PhDs? For that matter, just how many PhD students are there in the earth science departments? And to what extent do they match up to demand in both number and discipline? If it is true, as the report suggests, that the exploration companies "regard the years of training for PhD as a reduction in the working life of the men in question", is the PhD only of use as an entrance fee to a university teaching post or the Institute of Geological Science?

All this leads to even more fundamental questions. For one thing, it is hard to see how a rational evaluation of postgraduate training can be carried on separately from a consideration of undergraduate (and even school) education, if only because of the purely mechanical point that teaching and research are usually carried out under one roof. The fact is that the whole question of earth science education in Britain needs a thorough airing, but even a limited investigation of postgraduate training makes no sense in the absence of any clear thought about what Britain can do with limited resources. There is also the problem of too many earth science departments. The one truth that shines through the report is that many departments are quite simply too small to sustain viable research groups.

This said, the report does have some useful things to say. For example, it rightly criticizes the rigidity of the research council's policy of giving PhD support only to those with "good degrees"—which means upper second or first. But what emerges most clearly is the need for an overall strategy for the earth sciences in Britain. The authors recognize that future postgraduate training is only under the control of individual universities to a marginal extent—and the same could be said of all earth science education. The solution is to formalize this lack of control in a separate subcommittee of the University Grants Committee aided by the research councils. There are, however, other possibilities. The Higher Education Research Unit at the London

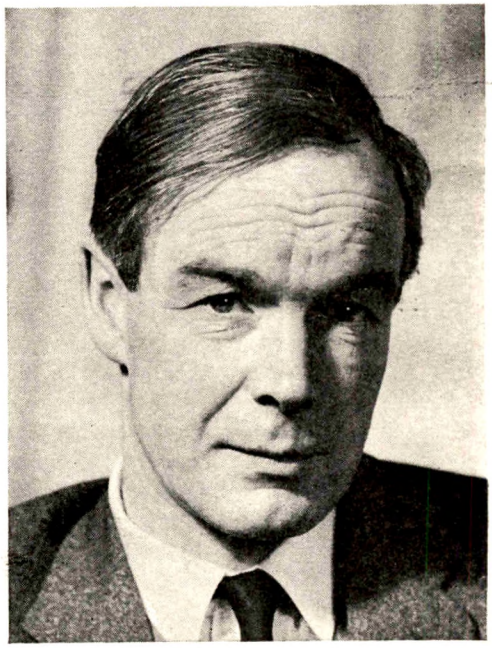
School of Economics, for example, has pioneered the study of general problems of higher education within the university itself. The time has surely come for the other units to consider individual disciplines. Or must policy in the earth sciences continue to struggle along from one *ad hoc* decision to another?

100 Years Ago

Natürliche Schöpfungs-Geschichte. Von Dr. Ernst Haeckel. 2te Auflage. (Berlin : Reimer, 1870. London : Williams and Norgate.)

We have, in the above, attempted to give a general idea of what the book is, and how the second edition differs from the first, rather than to enter into any criticism. The first edition has already received the ablest criticism this country could give. We will venture, however, to make one reflection. Had the book been written for scientific men, it would have been read by some with delight, by others with feelings of fretfulness and worry, but by all with more or less of profit. Addressed as it is, however, to an intelligent and cultivated, but still to a general and unlearned public, prone to receive fanciful analogies as real reductions to simpler laws, and to confound together fond imaginings with sound and fruitful hypotheses, we very much doubt whether it may not turn out to be an engine rather of mischief than of good. Genealogies there must be, doubtless, and many, doubtless, also may in time be made out. In cases like the pedigree of the horse, the evidence already seems wonderfully strong; and it would be simple presumption to fix a limit beyond which we cannot hope for success. Still, by their nature, genealogies are like castles of cards in the shape of inverted pyramids, with each tier less safe and less sound than the one above it. A very little memoir may disturb one of the lower stages, and then a whole pile comes down with a run. They are not the kind of things to put before learners as the strongholds of science. Some readers would learn in the first half of this volume to love Darwinism better than biology, and before they had finished the second half, would love Haeckel better than either. Others would pass rapidly through a disbelief in Haeckel and distrust of Darwin to a state of complete doubt about biology in general. Worst of all would be the effect on such minds as that of a speaker at one of the meetings of the Biological Section of the British Association at Liverpool, who said he had believed for many years in spontaneous generation, in natural selection, in the evolution theory, and in most views of a similar kind, and who seemed ready to believe anything and everything except the old truth, that truth is very hard to get, but very precious when it is gotten.

M. F.



From Nature, **3**, 102, *December* 8, 1870.

OLD WORLD

ROYAL SOCIETY

Looking Outwards

THE election of Professor Alan Lloyd Hodgkin, Plummer professor of biophysics at the University of Cambridge, as President of the Royal Society was announced after the anniversary meeting of the society on November 30. Professor Hodgkin, aged 56, a Royal medal winner in 1958 and joint Nobel laureate for physiology in 1963, is a widely respected biophysicist, best known for his fundamental research into the nature of the transmission of the nerve impulse. His most recent work has been directed towards elucidating the movement of metal ions across the nerve axon membrane as a succession of nerve impulses travel along the nerve fibre.

Professor A. L. Hodgkin. (Photograph by Ramsey and Muspratt Ltd.)

The annual report of the council and the final address by Lord Blackett, the retiring president, both emphasized the Royal Society's concern with, and involvement in, the international aspects of science especially in relation to Europe. Lord Blackett, in reviewing the year's activities, underlined the growing spirit of cooperation between the Society and the government in matters of international science policy. The European Exchange Scheme, started in 1967 and developing rapidly, is a fine example of this interplay between science and state. When it became clear that the original budget of £400,000 a year which the Society had found from private sources would be insufficient to support the fullest development of the programme, finance was arranged with the Department of Education and Science so that the Society was able to match sums made available by organizations in other countries. This scheme has made possible a total of 551 fellowships or study visits during the years 1967, 1968 and 1969.

The second part of Lord Blackett's address diverged from the purely scientific into the more sensitive area of the role of modern science and technology in improving the welfare of mankind. Stemming from a proposal made at the 1966 meeting of the International Council of Scientific Unions (ICSU), of which the Royal Society is a member, a study group was formed with the ponderous title of "Committee on Science and Technology in Developing Countries—Costed". The first fruits of this move are now apparent in the form of the draft of a book entitled *The Role of Science and Technology in Developing Countries*, written by Graham Jones, a chemist and administrator, under the guidance of Lord Blackett. What seems to have emerged from this study is that technology which may be meat to a rich country may equally be poison to a poor one. Although methods of production in under-developed countries must be improved, it is dangerous to provide the means of increasing the gross national product unless steps are taken to ensure that unemployment does not become a concomitant social problem. Regardless of how this conclusion may be received it is clear that the writing is on the wall for the suggestion that the work of the Royal Society ends at the horizons of the purely academic world.

EUROPEAN SPACE

Frustration in ESRO

from a Correspondent

IT seems that the diplomatic initiative of the European Space Conference (ESC) "hard-core" launcher countries—essentially, France, Germany and Belgium—was by no means exhausted by the failure of the ruse to raise $35 million, chiefly to support further work on the ELDO launcher (see *Nature*, **228**, 596; 1970, and **228**, 706; 1970). At what was to have been the final meeting this year of the ESRO Council to approve budgets for 1971, the French delegation last week frustrated the deliberations on the applications satellite budget which should have just begun to swing European work in this field into motion. The scientific satellite budget went through; this covers the funding for the HEOS-A2, TD-1 and ESRO-4 satellites, and preparatory work on the COS-B and GEOS satellites selected to follow on.

The Council had put to its member countries a draft applications satellite budget for next year of $11 million. Instead of either voting down or accepting this sum, the French delegation offered to pay its share (of about 20 per cent), but on only $1 million. This, of course, is a derisory amount, and the other delegations consequently reserved their positions on the applications programme. A decision on the draft applications satellite budget has now been postponed for a new meeting of the ESRO Council on December 22.

There can be little doubt that this manoeuvre was France's retaliation for the non-launcher members of the European Space Conference, and Britain in particular, not going along with the ELDO Europa 3 project at the November 4 Brussels meeting of the ESC. France has the biggest stake in Europa 3; Britain is identified closely with European applications satellites. Professor Hermann Bondi, until next autumn Director-General of ESRO, will have a busy month attempting to salvage the situation in time for the December 22 Paris meeting. He succeeded over the perhaps even more intractable problem of the TD satellite cancellation, so he may well find a way out of this difficulty. He is personally deeply convinced of the importance of pursuing an applications satellite programme in Europe.

PSYCHIATRY

Boost for Biochemistry

"BIOCHEMICAL studies within the broad framework of neurobiology offer a tangible approach to important aspects of mental functioning." That is the conclusion of a committee established by the Medical Research Council under the chairmanship of Professor D. A. K. Black (Manchester), which has just issued its report *Biochemical Research in Psychiatry: Survey and Proposals* (HMSO, 6*s*).

The theme of the report is that the problems of mental illness have not in the past attracted a share of research effort commensurate with their importance in medicine and in society. The biochemical approach, in particular, has been hampered by the complexities of the organization of the nervous system and by difficulties in recruiting suitably qualified research workers. Another contributory factor is the comparative isolation of many of the hospitals which cater for mental illness.

But because of recent scientific developments, the committee feels that circumstances have now changed so as to make such biochemical analysis opportune. The report suggests that the MRC should encourage more strongly the neurobiological approach to psychiatric problems and argues that the observation of correlates between abnormal behaviour and underlying changes in the nervous system is an important (albeit long term) approach to understanding behavioural disorder.

The report recommends that the career structure in this field should be improved and that the MRC should therefore contribute to a coordinated scheme for providing training and more senior posts. There should be additional support for strengthening existing units and for forming new teams to work in this area. The multidisciplinary character of the subject implies that this would be best exercised in a university with departments already established in the relevant supporting subjects.

The MRC is now studying the general recommendations of the report with a view to formulating specific policies. It seems likely that changes in the pattern of MRC expenditure will result (the recommendations of the last such report, on radiobiology, that support should be increased for radiotherapy but decreased for radioprotection were very largely carried out. There must therefore be a slight change in the balance of expenditure, for given limited funds, an increase in support for neurobiology must imply cuts elsewhere. Although these cuts have not yet been decided, the MRC is hopeful that their effect will be more limited than was at first anticipated.

This report marks a departure in MRC policy—it is the first time that such a policy review has been published in this manner (although policy reviews have been held frequently, and commented on in the annual report). The intention of this publication is to make the objectives of the MRC more widely known, and thus perhaps to encourage more interest in this field.

Comparable reports on other selected areas will probably be issued; a committee, for example, is at present examining MRC support for human physiology.

FRANCE

Instrument Development

THE French government, especially the Ministry of Industrial and Scientific Development, is seriously concerned about the state of the scientific instrument industry in France. The balance of payments in the French instrument trade has been deteriorating over the past few years (about £43 million of imports against only £25 million of exports in 1968, for example). The Organization for Economic Cooperation and Development drew attention to this disquieting fact as early as 1968, when the instrument industry was surveyed for its possible role in the technological gap. In fact, the Délégation Générale à la Recherche Scientifique et Technique (DGRST) has been struggling with this problem since 1964, when the delegation was part of the Prime Minister's office, the struggle having taken the form of financial aid for research and development done by a few selected instrument builders. But this so-called "concerted action" has yielded meagre results. Of the twenty-three subsidies paid by the state, amounting to £1·5 million, five can be considered successful, five more show positive results and three have been only partially successful. The trouble is not that state-supported research and development is intrinsically unfruitful but that the sowing determines the harvest. Research projects considered for funding through the DGRST are carefully screened, but although this organization requires market analyses of the products to be subsidized, the market studies often have proved to be erroneous. With the whittling down of the French research budget in the past two years, there has been a commensurate rise in the challenge presented by the American instrument market which, according to a Stanford Research Institute study of the market outlook, will continue to be 2·5 times greater than instrument sales possibilities in western Europe (including Britain) over the next five years.

Before the French Sixth Plan gets under way in 1971, the French government has decided to remodel, strengthen and supplement official aid to the scientific instrument industry. After a year of redefining the industry's responsibilities, a new interministerial guidance committee met on November 13 to spell out a "funding strategy". Following the strictest rules of continental bureaucracy, this committee seems to include no researchers (instrument users) or manufacturers (the suppliers), but only civil servants (who handle the cash). The DGRST, now a component of the Ministry of Industrial and Scientific Development, is represented, as is the Centre National de la Recherche Scientifique. But the committee's chairmanship (a task so essential to technocracy) is the responsibility of the same ministry's Direction des Industries Mécaniques, Electriques et Electroniques (DIMEE), an organization whose habit it is to become involved in matters where research and development plays a purely imaginative role.

The DGRST's aid to instrument research and development was the government's principal form of assistance during the current quinquennial Fifth Plan, now ending. Those concerned wish to see state fun doubled for the Sixth Plan. Marketing support will the secret weapon of the new committee, authors of green paper titled *Action Instruments de Mesure*. F exports, instrument makers will be urged to raise th sales to 20 per cent from the present 10 per cent annual turnover. For the domestic market, a centraliz purchasing mechanism is envisaged to encourage sta institutions (which make more than 50 per cent instrument purchases) to "buy French".

OIL POLLUTION

Unit Shows Its Paces

THE first results from the Field Studies Council's n oil pollution research unit near Milford Haven we presented this week at a symposium organized by t Zoological Society. During the past three years the has been much needed progress from the woeful sta of ignorance that existed at the time of the Torr Canyon disaster about the effects of oil on marine li and for this the unit can take some of the cred It was set up in the wake of the Chryssi P. Gouland episode when 250 tons of crude oil were released the shores of the Haven, now the home of Britain largest oil port and site of not infrequent oil spillag The unit's work is supported by the Institute of Petr leum and the World Wildlife Fund and although it h existed on £9,500 since it started in 1967, these grar are a rare example of cooperation between indust and conservationists. Much of the unit's work has be concerned with the effects of oil on salt marshes, t physiological effects of oil on plants and the effects detergent cleaning on rocky shores.

One of the more useful aspects of the symposiu was that oil was considered in relation to other pollu ants. The most notable contribution was that of t unit's director, Mr E. Cowell, in which he put forwa a rather refreshing view on the problems of oil pollutic Like others, he was anxious about alarmist reporti in the press: it is high time, he said, that the effects oil pollution should be put into some kind of perspecti in relation to the other environmental threats, partic larly those which are less obvious. He therefc suggested a six point scale of pollutants as a basis f allocating them some order of importance. He definec pollutant as anything which, having been introduc into the environment, subsequently causes a change the ecosystem and placed inert "additions" such polythene bottles in category I of his scale. Next car the environmental contaminants which cause sor biological change but which are not considered serio Oil pollution from refinery effluents and the prese level of radioactive waste could fall in this categor Ecologists would become anxious when hazards fr category III are rife; these would include chlorinat hydrocarbons and oil slicks. The public shows anxie at about stage IV when organisms begin to die and t ecosystem becomes unstable. The methyl mercu contamination of the Japanese rivers would come category V, the stage at which official action wou be automatic. Lastly, catastrophic pollution such that from nuclear, chemical and biological warfa would fall in category VI.

In Dr Cowell's opinion, the oil industry now pla only a tiny part in the total pollution of the wor ecosystem—a tribute, he says, to the vigilant an

pollution measures adopted by 80 per cent of the world's oil industry. At the same time it would be unwise to underplay the threat of oil pollution to marine life, even if damage is only on a local scale: many colonies of water fowl are still rapidly disappearing through the effects of oil and not even the remotest penguin remains unscathed.

CERN ACCELERATOR

Social Justification

THE chief justification for building the new 300 GeV accelerator at CERN is a social and political one, Dr J. B. Adams, the director of the project, told a meeting of the European Atlantic Group in London last week. With the governments of the twelve member countries of CERN now engaged on the task of deciding whether or not to support the new venture, estimated to cost £100 million, Dr Adams sought to place the new machine in the perspective of two important ideals—the development of university education in Europe and the need for some centre of European collaboration which could be seen to weather the storms that have scarred so many other European ventures.

Failure to build the new accelerator would have serious consequences for the universities of Europe, Dr Adams said. A significant part of the teaching capacity in physics departments lies with high energy physicists whose teaching is influenced by their involvement at the forefront of research in high energy nuclear physics. This would suffer if Europe dropped out of the high energy arena. The existence of broadly equivalent facilities at CERN, in the United States and in the Soviet Union means that many experiments take on a multinational character, with physicists from Europe gaining the right to use facilities elsewhere in return for outside participation at CERN. This partnership in high energy physics would soon disappear, Dr Adams said, if the new accelerator were not built at CERN. The 200 GeV machine at Batavia, Illinois, which should be completed within the next eighteen months, already has a waiting list of eighty experiments but the machine only has a capacity for about ten experiments a year.

Dr T. G. Pickavance, a director of the Science Research Council, explained that the cost to Britain over the eight year construction period would be about £2·5 million a year. The present contribution to CERN of £7 million would be increased to £9 million instead of dropping to £6·5 million. If any one country decided to opt out of the project it could still go ahead in principle, Dr Adams explained, as the existing 28 GeV proton accelerator would still be available for experiments by the non-contributing countries.

Dr Adams also emphasized the important part played by such a project in providing an advanced market for new technological goods. This is most likely to apply to the superconducting magnets which will be installed in the new machine if the present design hurdles can be overcome. The glaring absence of any overriding criterion by which to judge whether or not the new accelerator should be built, however, must place the fate of the 300 GeV machine very much on a knife-edge. But if the accelerator is to be built, this should be known by the time the CERN council meets next on December 18.

Parliament in Britain

Rolls-Royce

THE government, in March 1968, agreed with Rolls-Royce to supply 70 per cent of the launching aid for the RB 211 engine if either McDonnell Douglas or Lockheed came forward with three airlines ready to order aircraft with Rolls-Royce engines. But on March 27, Rolls-Royce asked Mr Anthony Wedgwood-Benn, then Minister of Technology, for £20 million because Lockheed had decided to go ahead with development of the TriStar airbus with orders from only two airlines. Moreover, the company said that unless the money could be promised within five hours, it would have to withdraw altogether from the race to secure the engine contract. Five and a half hours later, Mr Benn telephoned Rolls-Royce and said that the government would guarantee the company £9 million and Lockheed accepted the Rolls-Royce tender on the basis of that guarantee.

This extraordinary account was given last week by Mr Anthony Wedgwood-Benn during a debate on the government's recent decision to give a further £42 million to Rolls-Royce to launch the RB 211 engine. Proposing a motion which deplored the government's lack of consistency and of effective accountability in its industrial policy for the private sector, Mr Benn criticized the winding up of the Industrial Reorganization Corporation. The disappearance of the IRC, he said, means that there is no supervision over enormous sums of public money.

Mr John Davies, Secretary of State for Trade and Industry, maintained, however, that the decision to provide further launching aid for the RB 211 is in no way contradictory to the government's industrial policies. Rolls-Royce is not only a supplier to airlines throughout the world, but it is also at the very basis of Britain's defence procurement programme, Mr Davies said, and there is a long history of government support in the aircraft industry. Mr Davies also argued that the accountability of Rolls-Royce to its shareholders should provide sufficient control, and that the independent examination by accountants that the government has instituted should ensure extra safeguards. (Debate, November 23.)

CS Gas

MR IAN GILMOUR, Under Secretary of State, Ministry of Defence, said that CS smoke, as used in training, has no effects on the environment. The government, he said, has made extensive studies of the chemical and biological effects of CS smoke, which have shown that it has no effect on domestic animals and birds in the concentration that builds up in training. The amount that might fall on vegetation would also be very small, and would rapidly be dispersed by dew or rain. (Oral answers, November 26.)

Hepatitis

MR GORDON CAMPBELL, Secretary of State for Scotland, said that nineteen people died in Scotland from infective hepatitis and one from serum hepatitis last year. A further 976 patients were discharged from hospital with a diagnosis of infective hepatitis and twenty with serum hepatitis. A committee, under the chairmanship of Lord Rosenheim, is at present looking into the hazards involved in the treatment of chronic renal failure. (Written answers, November 24.)

The Biologist's Dilemmas

Do scientists have either the means or the power to influence the direction along which science advances or the uses to which scientific discoveries are put? In particular, should scientists now be worrying about genetic engineering, and all that the term implies, or are the possibilities so remote that they can conveniently be dismissed to the back of the mind? These were the two chief questions which occupied participants in the conference on the social impact of modern biology, held last week under the auspices of the British Society for Social Responsibility in Science. It is no surprise, nor should it be too great a disappointment, that very few answers emerged from the twenty-three hours of talk and discussion that the meeting provided.

The concept of social responsibility in science is in itself so wide-ranging that the meeting predictably rambled from issue to issue, without really getting anywhere. On one level, the concept embodies the moral dilemma of the individual scientist who participates in research whose results could be grossly misused. One speaker, for example, posed the question: what should a scientist do if he comes up with convincing evidence to show that one race is genetically more intelligent than another—should he bow to the dictates of his conscience as a scientist, and publish his findings, or should he keep quiet? On another level, social responsibility in science raises considerations of the role of science in society, and there were those at the meeting who argued that science cannot be discussed separately from the social system in which it is practised. This led some to suggest that changing the organization of science will not make scientists more socially responsible unless the social system itself is changed, and others to argue that the ethics of science are so far removed from the ethics of governments that scientists should seek to extricate themselves from the apparatus of the state.

But both these viewpoints to some extent beg the question of what scientists should be doing now to stave off some of the more alarming prospects conjured up by so-called genetic engineering. The consensus at the meeting was that although the prospects are still remote, possible consequences of research in molecular biology should now be borne in mind. The galaxy of talent laid on to address the meeting—nine Fellows of the Royal Society and three Nobel Laureates—ensured that the hall was filled and, as one member of the BSSRS unashamedly put it, that the meeting received wide press coverage. The papers presented fell into two chief categories. On the one hand, the present state of molecular biology was outlined and its social implications were aired, and on the other, the relationship between science and society was discussed.

The foundations for much of the discussion about genetic engineering were laid by Professor W. Hayes (Edinburgh), who outlined some of the chief concepts in molecular biology, and this theme was taken up by Professor M. R. Pollock and Professor G. H. Beale (Edinburgh). Both argued that the "horror stories" of genetic engineering are completely out of the question, at least in the foreseeable future, but, as Professor Beale put it, "it is no use smugly glossing over the possible harmful effects" of research in molecular biology. According to Professor Pollock, however, the real problems to tackle are those which involve eliminating some of the more common genetic mutations in man. "It is not too early to start thinking", he said, "of ways in which mutations such as those which cause gross mental deficiency and genetic haemophilia should be tackled." But it is a long step from defining the problems to devising a technique for solving them.

Professor Beale brought up the question of the dilemma facing scientists over the suggestion that males with XYY chromosomes may have a tendency towards psychopathic behaviour. If the theory is correct, there is a danger that perfectly normal males with XYY chromosomes will be wrongly labelled as potential psychopaths, and registration of a person's chromosomes will only reinforce such mislabelling. According to Professor Hayes, however, misconceptions about the relevance of XYY to psychopathic behaviour are based on quite inadequate information, and the chief problem is to prevent such suggestions from being taken as fact.

A salutary reminder of the limitations of research in molecular biology was given by Professor J. Watson (Harvard). "There is certainly enough money for applied cancer research", Professor Watson said, "and there will probably always be an excess of money in this field", yet "nobody should have any illusions that there will be a rapid answer". Professor Watson forecast that research during the next ten years may lead to an understanding of the chief biochemical differences between cancer cells and normal cells, but a cure for cancer still lies in the very distant future. He pointed out, for example, that if the cause of a particular cancer is a mutation in a single gene, it could take as much as one hundred years to pinpoint that gene.

As far as the funding of cancer research is concerned, Professor Watson said that a legislator always wants a solution to a particular problem immediately, preferably within his own term of office, and it is difficult to convince him that probably three decades of science are required to solve the cancer problem. But money will always be available for cancer research and Professor Watson argued that although much of it will be wasted, "if only 10 per cent were spent sensibly, it would be a greater percentage than that of most of the money spent in the United States".

A field of research which has been particularly prominent in all the speculation about genetic engineering is that of fertilization outside the body. Dr R. G. Edwards (Cambridge), whose research led last year to the controlled fertilization of a human egg *in vitro* and who is aiming, with Dr Patrick Steptoe, to implant such a fertilized egg back into the uterus to develop to term, discussed the implications

of his work. The crucial question, Dr Edwards maintained, is to balance the short-term benefits of such research against the possible consequences of genetic engineering. There is little doubt, he said, about the possible benefits. His research is likely to lead, in the relatively near future, to a technique which will enable women who have blocked Fallopian tubes to have a baby. It may also lead, in the more distant future, to a treatment for sex-linked genetic disorders, by selectively implanting sexed blastocysts back into the uterus.

But the methods employed by Dr Edwards may themselves lead to abnormal foetuses, and this raises the question of whether or not the foetus should be aborted. "There is no clash between scientific and medical ethics", Dr Edwards argued "if the rights of the patient and the foetus are safeguarded at all times". It should be up to the patient to decide whether or not the pregnancy should be terminated, and it is important at all times to balance the rights of two stages of foetal development. For example, use of the intrauterine contraceptive device implicitly balances the right of the blastocyst against the rights of the parents. Such a concept, Dr Edwards argued, obviates the necessity to define a point in foetal development at which it is considered that life has begun. Familiar arguments about whether or not life begins at conception or at birth cloud the issue.

But it was left to the audience to point to some of the more bizarre consequences of genetic engineering and the so-called test-tube baby. It was generally regarded that many of the speakers had skated round the more controversial problems, and the suggestion put forward by Professor G. Pontecorvo (ICRF) that the meeting was "a dreadful display of smugness and self-congratulation" received considerable support. "We are deluding ourselves", Professor Pontecorvo said, "if we regard genetic engineering as science fiction". He predicted that, within four or five years, molecular biologists would be capable of minor genetic modification aimed at preventing some genetic disorders.

What, in any case, can the individual scientist do to prevent the more bizarre and frightening developments in science from taking place? Or, more pertinently, can the social consciences of individual scientists somehow be fused into a coherent campaign for social responsibility in science? Here, the interrelationships between science and society cannot be ignored, and this was the other chief theme running through the conference. Debate on these issues was necessarily more vague and less coherent, and suggestions ranged from a self-policing system in the scientific community to excommunicate scientists engaged on, for example, warfare research, to radically altering society itself. The responsibility of the individual scientist to communicate his research findings, together with their possible implications to the public, was also often mentioned but inadequately discussed.

Professor J. Monod (Pasteur Institute) fired the first shots in the debate about science and society. He argued, during the opening session of the conference, that the values of science and the values of society are incompatible—science is founded on an objective valuation of knowledge, while society rests on a foundation of beliefs and ethics. But, Professor Monod maintained, the development of science itself relies on a series of value-judgments by scientists, and it is essential that these values be made explicit both to the scientist and to the layman. "Society feeds off science like a junkie", he suggested, and he foresaw many problems for society if it accepts scientific discoveries without at the same time adopting some of the objective values of science as well. It was also Professor Monod who asked, but did not answer, the question of what a scientist should do if his research produced results which were clearly open to misuse.

Professor Monod's thesis that scientific values and the values of society are incompatible was taken up by Professor J. Bronowski (Salk Institute), in the final lecture at the conference. Professor Bronowski argued that it is the duty of the scientist always to tell the truth. "Science", he said, "is an endless search for truth, and those that devote their lives to it must accept a stringent discipline. For example, they must not be a party to the hiding of truth, for any end whatever. . . . Science therefore rejects all those devices of expediency by which men who seek power excuse their use of bad means for what they call good ends". Herein lies the burden of Professor Bronowski's message, that the ethics of science and the ethics of governments are so disparate that scientists should "disentangle themselves from the apparatus of state".

"A pervasive moral distortion, a readiness to use any means for its own ends, warps the machinery of modern government", Professor Bronowski argued, and because most of the finance for scientific research now comes from government sources, the scientist is increasingly having to conform to the goals of governments in his activities. He therefore faces "a choice between two moralities: the morality of science and the morality of national and government power", and his only hope of maintaining his integrity lies in disassociating himself from government machinery. Pressed by a questioner to define how this should be done, Professor Bronowski suggested that scientists alone should control the funds for their own research, because only in this way could science be directed along the paths leading to a search for truth, and still remain free from the corruption of power.

But this élitist argument did not appeal to many of the participants in the meeting, who argued that science and its values can never be separated from the values of the society in which it is practised. In a closely argued lecture, for example, Dr R. M. Young (Cambridge) maintained that value-free science is a myth. Drawing on the examples of the debate about evolution in the nineteenth century, and of Lysenko genetics in the Soviet Union, Dr Young concluded that "science is no substitute for morality or politics nor is it independent from them". Moreover, "ideology is an inescapable level of discourse and is needed (in the first instance) to debate conflicting ideological positions and (in the last instance) to face and resolve the inevitable conflicts between needs and goals of men in the appropriate way".

The meeting was therefore swept by opposing winds. The debate was often muddled and incoherent, jumping from issue to issue, with participants putting forward well-worn arguments. But the chief value of the meeting was that the issues facing many biologists now and during the next ten years were given an airing, and there will also be a chance to read the full proceedings in a less confused and heady atmosphere when they are published next year.

NEW WORLD

Fulfilment Lags Promise in Biology

by our Washington Correspondent

A MASSIVE increase in the scale of government support for the life sciences is urged in a survey issued this week by the National Academy of Sciences. The gist of the argument is that in all the nationally important problems on which biology can be brought to bear—whether in curing disease, controlling population, improving agriculture or safeguarding the environment—the present biological research endeavour is being depressed below its full capability by a severe shortage of funds.

The new report*, the last in a series of surveys of various scientific disciplines, is the work of a committee with Dr Philip Handler as chairman in the days before he became president of the National Academy of Sciences. Based in part on a couple of questionnaires sent out in mid-1967 to more than half of the 24,000 biological research workers in the United States, and to more than 1,000 heads of academic departments, the report provides a wealth of statistical insight into how biologists spend their time and money, what instruments they need, use or lack, and what they would do with more money if they had it. From this information together with an appraisal of the present frontiers of biological research, Dr Handler's committee has arrived at a number of general conclusions concerning both the directions that should be pursued by pure and applied researchers and the ways in which the organization and support of biological research should be remoulded to support these pursuits most efficiently. To a large extent the proposed remoulding is simply a call for more money, and the committee has furnished what critics may regard as a shopping list, but what may more usefully be seen as an ordering of priorities. Among the chief proposals of the National Academy of Sciences committee are the following:

● SUPPORT OF ACADEMIC RESEARCH. Federal government funds for research in the last financial year were "approximately 20 per cent less than required to ensure that the nation's truly qualified academic life scientists are fully and usefully engaged". The committee urges that this deficit be made up as soon as possible and that thereafter "the research-support system grow at a rate commensurate with the ability of the system to utilize such funds efficiently and wisely". The committee believes that a 12–15 per cent growth rate is desirable.

● INSTITUTIONAL SUPPORT. Graduate and professional education and research should be supported by the federal government but the practice of paying faculty salaries out of research grants constitutes a "most undesirable distortion of the internal arrangements of academic institutions". For this reason programmes of block support should be instituted to enable universities to pay all faculty staff out of funds controlled by their own administrators.

● GRADUATE EDUCATION. The budget for graduate education in the present financial year is a serious underestimate of the need. "It is our hope that appropriations for these programmes will be doubled over the course of the next five years." The National Science Foundation should expand its training grant programme along the lines of that conducted by the National Institutes of Health.

● UNIVERSITY CURRICULA. The committee notes that the pace of research has long since outstripped the pace of educational reform in the life sciences; a new curriculum containing the core of material central to all biological sciences should be prepared and presented to all undergraduate students majoring in biology.

● DEPARTMENT OF AGRICULTURE. The committee regards as unfortunate the failure of the Department of Agriculture to support biological research conducted outside the agricultural schools and its own in-house laboratories; the Department should set up a broad research grant programme similar to that administered by the National Institutes of Health.

● HEALTH RESEARCH. Within the budget of the National Institutes of Health, research for improving methods of delivering health care should not be allowed to grow at the expense of funds for basic research.

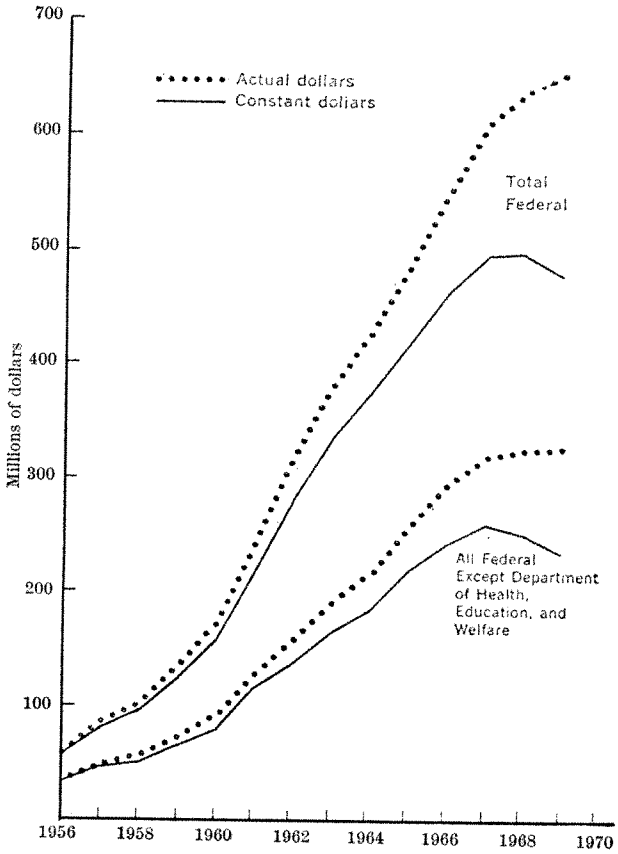


Fig. 1. Federal support for research in the life sciences expressed in absolute dollars (continuous line) and in 1965 dollars (broken line).

*_The Life Sciences_ National Academy of Sciences, 1970. Pp. 526.

Fig. 2. Reasons given for limitations of research programmes

Limiting factor	Academic scientists		Non-academic scientists	
	Number	Per cent	Number	Per cent
Grand total	7,007	100	3,076	100
Space	3,529	50	1,277	42
Budget for:	5,399	77	2,187	71
Supplies	1,779	25	371	12
Equipment	2,806	40	803	26
Professional staff	1,554	22	957	31
Technicians	3,353	48	1,454	47
Clerical-Administrative	1,169	17	404	13
Student stipends	1,742	25	196	6
Postdoctoral stipends	1,621	23	339	11
Computer time	245	3	100	3
Travel	1,329	19	661	21
Insufficient research time due to:	3,429	49	1,118	36
Heavy teaching responsibilities	1,851	26	75	2
Service	848	12	371	12
Administration	1,913	27	867	28
Unfilled funded positions for:	1,446	21	725	24
Professional staff	759	11	430	14
Technicians	832	12	432	14
Clerical-Administrative	149	2	62	2

● EQUIPMENT. The National Institutes of Health and the National Science Foundation should set aside funds (about $25 million a year) to pay for particularly expensive or unique instruments. The two agencies should also be prepared to grant $100 million a year for constructing laboratories in biological and medical research laboratories (the committee has identified a backlog requirement of about $150 million for construction of laboratory space). Funding agencies should be increasingly prepared to countenance demands for computer use in grant requests, an activity which will soon be consuming some $50 million a year. Money is also needed to sustain museums and upgrade marine biology stations.

The prospects of finding the money for any of these recommendations in the budget now under preparation are dim, to say the least. The Academy's reports covering physics, chemistry and astronomy have not yet been implemented in any significant way and, as Dr Handler conceded this week, science does not have a very high priority at present with the Office of Management and Budget. But even if the specific recommendations should be ignored, the Academy's efforts at delineating the social system in which life scientists work will still be of value, even if only as a benchmark with which to measure the future state of the system.

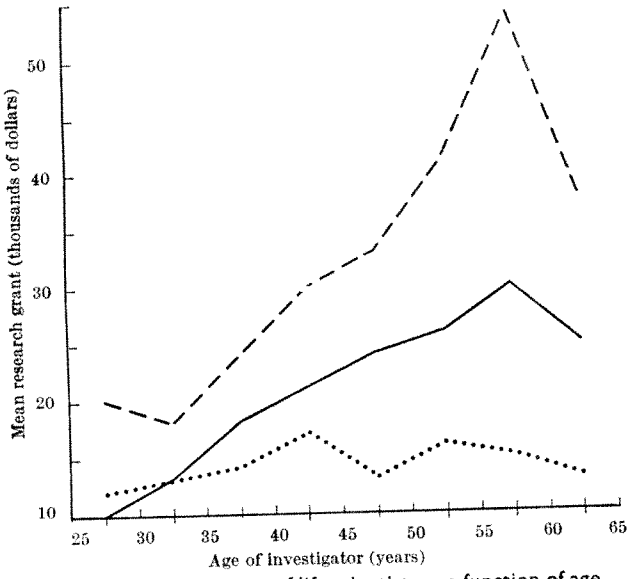

Fig. 3. Research support of life scientists as a function of age. ----, National Institutes of Health; ———, all sources; . . . . , National Science Foundation.

Overall federal support of the life sciences, when expressed in terms of constant dollars, started to fall in 1968 (see Fig. 1). The Academy's questionnaires were sent out too early to record the full impact of this decline, and the inadequacies already apparent in the latter half of 1967 have presumably worsened accordingly since then. For example, the questionnaires identified serious constraints on individual research programmes with respect to laboratory space (cited by 50 per cent of respondents), budget for professional staff (reported by 40 per cent), and other factors related to the level of funding such as time available for research (see Fig. 2). From these statements and others the Academy committee has arrived at the estimate (quoted above) that the deficit between current support of life science research and a level commensurate with current capability is between 20 and 25 per cent.

Both individual scientists and chairmen of academic departments reported unmet needs for a variety of major instruments, with electron microscopes being the first priority of 9 per cent of respondents, followed by amino-acid analysers (top of the list for 8 per cent) and small specialized computers (7 per cent). But instruments rank comparatively low on the overall list of first priority needs to improve current research; of a thousand chairmen of academic departments nearly 300 reported that funds to pay additional faculty were their first requirement, and a quarter rated top priority to stipends for predoctoral students.

Support of predoctoral students is viewed with particular concern by Dr Handler's committee, which states that stipend levels have failed to keep pace with the rising cost of living. The committee also deplores the failure of certain agencies—the Department of Agriculture, the Atomic Energy Commission, the Department of Defense and NASA—to make any significant contribution towards the cost of training PhDs.

Other notable features of the report include the following findings:

● Seven per cent of all budgeted positions were unfilled in 1967, ranging from 5 per cent for schools of agriculture to 8 per cent in medical schools.

● Some 38 per cent of all postdoctoral fellows in the life science research community are not of American origin, and about one sixth of these had obtained their doctoral degrees within the United States; the committee regards this proportion as "not seriously excessive" in view of the contribution of foreign postdoctorals to research progress.

● More than 30 per cent of those responding to the questionnaire indicated their research is very seriously hindered by insufficient personal training in various non-biological disciplines such as chemistry, computer science, mathematics and statistics.

● The average life scientist employed in an institution of higher learning devotes about half his time to research, between 10 and 20 per cent to administration, a quarter to a third of his time in teaching and the rest to "assorted other responsibilities" such as patient care.

UNEMPLOYMENT

No Niche for Aerospace Industry

by our Washington Correspondent

DESPITE the chronic unemployment afflicting the defence and space industries, the Administration has no intention of creating a favoured niche for such companies in the environmental protection business. In hearings held last week before the House Subcommittee on Conservation and Natural Resources to consider how the skills of aerospace companies could be transferred to cleaning up the environment, government spokesmen made it clear that there would be no large-scale federal support for the research necessary to effect such a transfer, and that if the aerospace industries cannot fend for themselves in open market competition, the Administration will observe John Clare's improved commandment, "Thou shalt not kill, but needst not strive officiously to keep alive".

According to a survey published last month by the Aerospace Industries Association, total employment in the aviation and space industry will have dropped by some 16 per cent in the twelve months ending next March, from 1,238,000 to 1,044,000.

Some of this unemployment, which it has long been foreseen would attend the inevitable reduction in military and space spending, could perhaps be alleviated if the aerospace companies were successfully to transfer their skills to the problems of environmental pollution. In its simplest terms, as stated by Representative Henry Reuss in opening last week's hearings, this proposal boils down to thinking that the answer to deterioration of the environment is to "have the same people who got us to the Moon go to work on cleaning up pollution".

One of the troubles with this theory is that the market for anti-pollution technology has remained strangely small, despite the incessant sounds of movement against pollution in Congress, and so far the aerospace companies seem in any case to have captured a rather exiguous share of what business is going. A possible reason for this failure was suggested by Mr Murray L. Weidenbaum, Assistant Secretary of the Treasury for Economic Policy, who despite his former employment as corporate economist for the Boeing Company, had some distinctly unflattering remarks to make about the aerospace industry's attempt at diversification. "There has been a great deal of naïveté in attempting to sell the systems ability of the aerospace industry as a cure-all for public sector needs," he told Congressman Reuss's subcommittee last week. "One industry president has been quoted as saying, 'Creating a system to warn a field army the enemy has launched an attack of germ warfare is basically no different from creating a system to control juvenile delinquency'. Or, to parody Gertrude Stein, a system is a system is a system."

The upshot of this way of thinking is that the various diversification projects of the aerospace industry, ranging from powered wheelbarrows and canoes (which exploited transportation skills) to wall panelling and coffins (which exploited the ability to fabricate light metals) have typically led to meagre profits or outright losses. "Personally", Mr Weidenbaum remarked, "I believe that the focus of the present inquiry needs to be reversed. The national interest is not well served by viewing the question as to how to employ the aerospace industry or any other single industry in solving pollution and other environmental problems. Rather, we need to start with the problems to be solved and then see what technology and other capabilities are needed." The public interest would best be served by letting the aerospace and other companies compete for the emerging environment market, and if the federal government were to allot any relocation allowances, Mr Weidenbaum would prefer to see them go to veterans returning from Vietnam rather than out of work aerospace employees who in general "have been one of the highest paid groups in our society".

The substance if not the cutting edge of Mr Weidenbaum's views was echoed by the President's Science Adviser, Dr Edward E. David, who told the subcommittee in roundabout terms that the Office of Science and Technology is not contemplating any large-scale research programme to help the aerospace industry diversify into the anti-pollution business. Dr David mentioned as an incentive for industry to invest in pollution control technology the possibility of taxing polluters on the theory that the nation's air and water are common property and anyone who discharges wastes into them should pay for the privilege, only to add that he was "too new on the job to have formed an opinion on this option". In any case, to judge from a written appendix to Dr David's testimony prepared by the staff of the Office of Science and Technology, it appears that the OST has yielded precedence on matters of environmental research to the recently instituted Council on Environmental Quality: "Our role with respect to environmental research", the statement explains, "involves a special relationship with the Council on Environmental Quality, which has overall responsibility for environmental concerns at the Executive Office level. OST, as in the past, will be consulted with respect to the research and development initiatives of the agencies and from time to time undertake special reviews and analyses, bearing particularly on the basic science underlying environmental decisions and on the provision of technological alternatives for solving environmental problems."

By limiting his inquiry to the environmental issue, Congressman Reuss seemed to be offering at once too narrow and too diffuse a solution for a real enough problem. A bill proposed over a year ago by Senator Edward Kennedy stands a better chance of tackling unemployment at its roots, though less of winning the favour of the Administration; his Conversion Research Education and Assistance bill would assign $450 million over a three year period for converting people and resources from defence to civilian problems. The bill would establish as national policies that "scientists should have continuing opportunities for employment, in positions commensurate with their professional and technical skill. Second, federal funding for civilian research and development should be raised to a level equivalent to defence-related research and development. Third, the total federal investment in science and technology should continue to grow annually in proportion to increases in our gross national product." The programmes envisaged by the bill would be administered by the National Science Foundation, the Department of Commerce and the Small Business Administration.

CONSERVATION

Axe Falls on Hickel

by our Washington Correspondent

CONSERVATIONISTS lost one of their firmest friends in the Administration last week with the summary firing of Secretary of the Interior, Walter J. Hickel. Mr Hickel, a former governor of Alaska who campaigned effectively for President Nixon in the 1968 elections, was sacked on the eve of Thanksgiving, and six of his closest aides at the Department of the Interior followed him the next day.

Mr Hickel's departure has been only a matter of time ever since his leaked letter at the period of the Kent State shootings in May which criticized President Nixon for being out of touch with students. The strong constituency he quickly built up with conservationists may be one of the factors that have delayed his dismissal until now. Mr Hickel became Secretary of the Interior two years ago to the bitter opposition of the conservationist lobby and after personally humiliating hearings before the Senate Interior committee. Having made his fortune in real estate and construction in Alaska, Mr Hickel seemed unlikely to be sympathetic to environmental issues, an impression borne out by some of his remarks at the time. He had no obvious qualifications for the Interior post and President Nixon's campaign pledge to appoint a Western governor seemed to be the chief factor behind his elevation.

Shortly after he took up office, Mr Hickel must have seen the light about ecology, or at least realized that preservation of the environment was the political rallying cry of the future. With the sudden zeal of the converted, he proceeded to confound his former foes and friends by deciding a number of important issues in a manner quite contrary to what each was expecting of him. After the blow-out at the Union Oil well in the Santa Barbara channel, a few weeks after his appointment, Mr Hickel ordered a cessation of offshore drilling operations in the region and a moratorium on new leasings until stricter regulations had been developed. He had the Chevron Oil company prosecuted when its oil well in the Gulf of Mexico ran out of control in March this year and more recently he instigated suits against companies polluting public waters with mercury effluents.

Mr Hickel's final act in office was his announcement last week that the United States would import no more products made of whale and that eight species of whale—the fin, sei and sperm (these are the main commercial species) together with the bowhead, blue humpback, white and grey whales—were to be placed on the list of endangered animals. Insofar as the United States imports nearly a third of the world's whale products, this decision should be of some help in saving whales from extinction.

Had Mr Hickel stayed in office three days longer, his views on the Alaska pipeline would have been known. The proposed pipeline, which would carry oil from the North Slope strikes down to the ice-free port of Valdez on Alaska's southern coast, has been opposed by conservationists on the basis that if built underground the heat of the oil would melt the permanently frozen soil, causing erosion, earth slides, and the destruction of the fragile tundra, while if built above ground the pipeline would obstruct the migration paths of the caribou. The oil companies involved on the North Slope have already bought some 600 miles of pipe.

A decision on the pipeline—there are also native land claims and a conservationist injunction to be settled before any construction can begin—will now be delayed until after Mr Hickel's successor has taken office in the new year. He is Mr Rogers C. B. Morton, a Representative from Maryland now serving his fifth term and chairman of the Republican National Committee. Mr Morton holds no particular record as saviour of the environment but is said to be much devoted to fishing. On a recent rating prepared by the League of Conservation Voters in which Representatives were scored for their voting record on ten environmental issues, Mr Morton unfortunately received minus 14 points out of a maximum of plus 28 (pro-environment) and a minimum of minus 28 (anti-environment).

RESEARCH FUNDING

Mansfield Champions Science

by our Washington Correspondent

A STRONG statement in favour of keeping the national research effort at least up to its present strength was made by Senator Mike Mansfield, the Majority Leader, during the Senate debate on appropriations for the Department of Health, Education and Welfare. Senator Mansfield, author of the now defunct amendment that restricted the Pentagon's research to matters with obvious military relevance, said in the Senate debate on November 20 that "for the Federal Government to act in a responsible manner, the civilian Federal agencies that sponsor basic research should have their budgets increased at least by an amount reducted from the Department of Defense. In fact, the amounts should also reflect the loss of the research purchased because of inflation".

Commenting on the bill's provision for research at the National Institutes of Health—the recommendation is for a $129 million or 12 per cent increase over the sum requested by President Nixon—Senator Mansfield said he believed these additional sums were "perfect examples of money well spent and the re-allocation of resources through the civilian sector which might otherwise have been channelled through the Defense Department. I would hope that the additional moneys recommended by our committee and earlier by the House of Representatives will be expended so that the great pressures on the research community in this country will be alleviated". Final action on the bill depends on reconciliation of the House and Senate versions, both of which include considerably more for medical research than requested by the Administration. Only the Senate version, however, includes provision of $15 million for the conversion of the biological warfare facilities at Fort Detrick to civilian use.

SELENOLOGY

Moon Revealed by Apollo 12

by our Astronomy Correspondent

It is now a little more than a year since the last Moon landing, and NASA marked the anniversary by gathering together some of those responsible for the instruments left behind on the Moon, and one of the astronauts who put the instruments there, Alan Bean. But with the possibility of further cancellations in the Apollo series being openly recognized, the event was not as cheerful as it might have been. Dr Frank Press of MIT, who was there to provide a summary of what has been achieved by the Apollo instrument package, said that it would be a pity if the exigencies of the moment were to deflect the United States from the further exploration of the Moon. The meeting also caught NASA employees looking over their shoulders at the Soviet successes with Luna 16 and 17. Alan Bean for one poured some cold water on the Soviet attempts to explore the Moon from the safety of a control room on the ground: "Apollo 11 brought back 50 pounds of rocks. We brought back 75 pounds. And the Russians on their last one brought back two-tenths of a pound. If the Russians were bringing back 50 and 75 pounds and we were bringing back two-tenths of a pound, think how you'd feel. I don't think we'd be so doggone excited as we (*sic* they ?) are about their two-tenths of a pound".

All the experimenters had fascinating tales to tell, but it is the results from the seismometer which have captured the imagination. It is now clear, for example, that tidal strain is causing moonquakes when the Moon is at its nearest to the Earth, an effect which has been looked for on the Earth many times without success. If the only strain present was due to the tidal effect the slip would be first in one direction, and then the other, but oddly the indications are that the slip is always in the same direction. This is interpreted to mean that there is another source of strain within the Moon whose release is triggered once a month by tidal effects, and Dr Gary Latham (Lamont-Doherty Geological Laboratory) and his collaborators have recognized nine locations around the Apollo 12 station where the strain is being released. Each location gives a set of signals that are identical in every respect, and there are nine sets of these matching records, one of which appears to originate within the Fra Mauro crater close to a set of rilles and not far from the Apollo 14 landing site. Fortunately with moonquakes being no stronger than between magnitude 1 and 2 on the Richter scale, there seems to be no threat to the Apollo 14 crew.

What the source of the strain can be is unknown. The total energy release amounts to only 10^{-12} that of the annual energy release by terrestrial earthquakes, however, and this seems to rule out the possibility that the interior can be molten except in a few minor pockets. It could be, Latham speculated, that the Moon is expanding slowly as a result of radiogenic heating. Other possibilities being considered are that a residual effect from large impacts is being observed, or that local hot spots are responsible.

A second type of moonquake which does not fit the monthly pattern has been attributed to the impacts of meteorites, and the frequency and strength of these moonquakes should lead eventually to an estimate of the amount of rock-sized fragments in space. As a preliminary indication Latham and his group say that kilogram-size meteorites strike the region up to 200 km from the seismometer on average once a month.

What do the experiments say about the interior constitution of the Moon ? The key here comes from the seismometer records following the two artificial impacts. The famous reverberations are taken as indicating that the mare is made up of loosely consolidated rubble that becomes increasingly compacted with depth down to at least 20 km, the greatest penetration reached by the artificial signals. This of course rules out a lunar equivalent of the Mohorovičić discontinuity, but leaves several possibilities for the origin of the surface material—pulverization of the original rock by impacts; removal of the original rock by a large impact, followed by flooding of the crater with lava and subsequent pulverization; or even that the rubble represents material swept up from the solar system during the final stage of accretion of the Moon.

Information about depths greater than the 20 km penetration of the seismic signals comes from the magnetometer which indicated a magnetic field of 35 gamma, only 10^{-3} that of the terrestrial field at the equator but more than people expected assuming a cold Moon. This appears to be a paleomagnetic field which could have originated during a conjectured close approach into the Earth's magnetosphere, or by the dynamo process which in turn implies that the Moon at one time had a hot interior. More important for an understanding of what the interior of the Moon is like at present is the comparison of the field measured at the surface of the Moon with that recorded by the space probe Explorer 35 in orbit around the Moon. The comparison indicates that the solar magnetic field is generating eddy currents inside the Moon, detected by the surface magnetometer, and the decay of the currents gives values for the conductivity and temperature. According to Dr Charles P. Sonett (Ames Research Center) reporting for the magnetometer team the data fit a model in which the temperature is increasing into the Moon by 2 or 3 degrees per kilometre. Sonett suggested a core temperature of perhaps 1,000° C, and if this is not exceeded at the centre then none of the rock need be molten.

The other experiments left by Apollo 12—the solar wind spectrometer and the suprathermal ion detector—refer to the environment around the Moon, chiefly the solar wind, but measurements taken following the impact of the Apollo 13 Saturn 4B stage might have something to say about the constitution of the lunar surface layers. As well as plotting the time variation of the solar wind, particularly as the Moon swings through the Earth's magnetotail, the two instruments picked up what seemed to be swirling clouds of ions shortly after the rocket impact. Oddly enough, the impact was downwind of the instrument package. The suprathermal ion detector recorded the cloud twenty seconds after the impact as a burst of ions with energies up to 500 eV. The acceleration mechanism is something of a mystery. Within a minute or two of the impact the cloud was observed by the spectrometer. According to Dr John Freeman (Rice University) the origin of the ion clouds is less likely to be the remaining fuel in the rocket's tanks, than gases such as helium, argon and krypton held in the surface layers of the Moon.

NEWS AND VIEWS

Footprints of Human Cancer Viruses?

THE discovery that RNA tumour viruses contain polymerase activities capable of reversing the familiar direction of genetic transcription, by using RNA as a template for the synthesis of double stranded DNA, has from the beginning promised an extraordinarily rich harvest for cancer researchers, and, after only six months, the first fruits are being gathered. At the recent Lepetit colloquium on the biology of tumour viruses (*Nature*, **228**, 609; 1970) several groups announced, after weeks of rumours and anticipation, the detection of reverse transcriptases in human leukaemic cells. This week, *Nature* includes what seems to be the first detailed account of this momentous discovery.

On page 927, Gallo, Yang and Ting report that extracts of the leukaemic lymphoblasts of three patients with acute lymphoblastic leukaemia contain an RNA dependent DNA polymerase activity. This activity cannot be detected in extracts of normal lymphoblasts taken from forty-eight healthy people, even after the cells have been stimulated to divide by exposure to phytohaemagglutinins. The extracts which Gallo and his colleagues have made are only partially purified and the RNA dependent DNA polymerase activity is admittedly very low; further, their assay conditions are clearly very far from optimal. But in spite of these limitations they have been able to characterize some of the properties of the polymerase. It is dependent on magnesium ions, on the presence of all four deoxyriboside triphosphates and on the addition of an RNA template, either rat liver RNA or the synthetic RNA poly rA·poly rU. Moreover, N-dimethylrifampicin, a derivative of rifampicin which Green and his colleagues have shown inhibits the RNA dependent polymerase activity in RNA tumour viruses, inhibits the polymerase activity in the extracts of leukaemic cells, although complete inhibition is only achieved with very high concentrations of the antibiotic. Finally, the product made by the reverse transcriptase in leukaemic lymphoblasts is resistant to hydrolysis by ribonuclease and alkali but is degraded by deoxyribonuclease.

All these characteristics point to one conclusion, namely, that the activity Gallo and his colleagues have detected in the leukaemic cells is essentially identical to that in the avian and mammalian RNA tumour viruses. Any doubts about this were removed by the more extensive investigations reported at the colloquium by Spiegelman and his colleagues, who, using a better assay system and more purified extracts, had then detected a polymerase activity, dependent on synthetic RNA/DNA hybrids, in extracts of cells from nine leukaemia patients and have since considerably increased this tally. But what is the significance of these findings? Clearly they raise the hope that a sensitive assay for reverse transcriptases may prove to be, at the very least, a useful tool for the diagnosis of leukaemia and perhaps other forms of cancer, if the cells of solid tumours are also found to contain these activities. Furthermore, should it prove that reverse transcriptases only occur in tumour cells of adults, it may be possible to exploit their presence in chemotherapy.

The discovery of these enzyme activities in human leukaemic cells can be interpreted also as suggestive evidence that at least some human cancers have a viral aetiology. So far the search for human, or for that matter primate, RNA tumour viruses has proved fruitless. The events of the past six months, however, should not only add impetus to the search but also provide new experimental approaches to the problem. For example, Todaro and his colleagues announced at the Lepetit colloquium that antibodies against the group specific antigens of murine sarcoma viruses inactivate the reverse transcriptases not only in the murine sarcoma and leukaemia viruses, but also those in the corresponding rat, cat and hamster viruses. The outcome of experiments to test whether these antibodies inactivate the polymerase activities in human leukaemic cells are awaited with interest. Should the result be positive and should significant inhibition be detected, the obvious implication will be that human leukaemia viruses do exist. And it would be no great surprise if the only footprints these putative human cancer viruses leave behind as a clue to their existence consist of the reverse transcriptases, for, as Aaronson, Todaro and Rowe have shown, when murine sarcoma

virus transforms certain mouse cells growing in tissue culture the transformed cells neither bud progeny virus nor contain any detectable viral antigens. Whether these murine cells gain the two polymerase activities as a result of transformation has yet to be determined.

Unlike a great deal of current research into tumour viruses and their interactions with cells, which in the short term at least seems to have all too little relevance to cancer as a clinical disease, the work on reverse transcriptases may quite soon find clinical applications. Pollack, Wolman and Vogel, who on page 938 of this issue of *Nature* report an analysis of the correlation between the malignancy and the chromosome count of spontaneously and virally transformed cells grown in culture, suggest that their work may also have clinical interest. Pollack and his colleagues find that an increase in the number of chromosomes in a transformant correlates with a loss of several of the characteristics of the transformed state. It is as if an increase in the number of chromosomes somehow suppresses the transforming effect of a resident viral genome in a transformed cell, and the parallels between this observation and the suppression of malignancy by fusing a malignant and a non-malignant cell, which Harris and his colleagues have reported, are obvious enough.

Pollack and his colleagues report, for example, that mouse cells of a line transformed by SV40 have a median chromosome count of 75. Revertant cells selected from this line exhibit many of the properties of untransformed cells—like untransformed cells they grow to a low density in culture, they are not agglutinated by plant agglutinins and they are less malignant than transformed cells—although they retain the SV40 genome, and these revertants have a median chromosome number of 118. Further, cells with the phenotypic characteristics of transformants back selected from the revertants have a median chromosome number of 72. In other words, when revertants shed chromosomes they return to the transformed state.

The molecular mechanism by which an increase in the number of chromosomes leads to the selective inactivation of the transforming function of tumour viruses are at present obscure although it is open to experimental analysis. But irrespective of the mechanism by which hyperploidy may suppress malignancy, Pollack *et al.* point out that their observations may explain why relapses so often follow remissions during the chemotherapy of human cancers. In essence they suggest that many chemotherapeutic drugs now in use are known to have, or may well have, the potential to induce hyperploidy in cells. It may well be that although such drugs kill most cancer cells they induce the formation of a reservoir of hyperploid revertant cells. Such revertants would have growth properties similar to undiseased normal cells and they might well survive the killing effect of further doses of the drug. At the same time they might act as a persistent source of back revertants, cells with a low chromosome number and high malignancy. Such back revertants would proliferate once chemotherapy was stopped and so change remission into relapse.

PROTEIN STRUCTURE

Facts and Prediction

from our Molecular Biology Correspondent

Some little time has now passed since the notion was first seriously mooted that it might be possible to "explain" the structure of globular proteins, in the sense that the native (by implication lowest-energy) conformation could be uniquely predicted from the sequence, by taking into account only a modest number of long and short-range interactions. Encouraged by a degree of success in calculating the stablest structure of homopolypeptides, and beguiled by the glitter of their objective, a number of groups of workers followed this *ignis fatuus* into a theoretical morass, in which they have for the most part now been lost to view. True that some interesting lessons emerged. Scheraga and his colleagues (Lewis *et al.*, *Proc. US Nat. Acad. Sci.*, **65**, 810; 1970) have recently, for instance, calculated the tendency towards α-helix formation in random chains corresponding in sequence to the globular proteins of known structure. Such calculations (which some theoreticians might even feel it is jumping the gun to contemplate at this stage) demand some intrepid assumptions, but the strategy is interesting, and the results so far even somewhat encouraging: those parts of the chain, it seems, which are most likely to be α-helical tend also to be helical in the native structure. That is to say interactions between different parts of the chain in the compact globular molecule do not override the secondary structure that the sequence alone tends to impose within each segment.

This is not perhaps a startling result, but tangible none the less. Atassi and Singhai (*J. Biol. Chem.*, **245**, 5122; 1970) have prepared fragments of myoglobin, and examined their conformation by optical rotatory dispersion. All contain an appreciable proportion of α-helix, but much less than in the protein. Thus a 32-residue fragment from a long helix in the protein is no more than one-third helical in water. Earlier work also suggests that this is a very general situation, and that inter-segment interactions are of extreme importance.

The travails of the theoreticians lend added point to experimental attempts to come by the rules of chain folding by way of non-covalent recombination of fragments. This approach has been pursued to great effect in Anfinsen's laboratory, especially on staphylococcal nuclease. In the latest paper, Chaiken and Anfinsen (*ibid.*, 4718) have synthesized a series of N-terminal fragments for recombination with the C-terminal residuum, comprising residues 49–149. The fragment 6–47, for example, recombines to give a substantially active enzyme. Fragments 9–47 and 10–47 also regenerate activity, but as judged by proteolytic resistance of the product, and the fluorescence change, which shows the extent to which the one tryptophan is engulfed in the refolded structure, they bind much less strongly. Shorter fragments, from 11–47 to 18–47, give no active product. Even here, however, their presence promotes the association of the residual chain with antibodies to the native enzyme, so that at least in the ternary system features of the native structure must be present in tangible concentration. Evidently a few residues, notably 9 and 10, are involved in conformationally crucial interactions, which direct reassociation with refolding.

Ripples, meanwhile, are still spreading from the first successful experiment on recombination of fragments by Richards, who regenerated activity from the S-peptide (residues 1–20) and the residuum (S-protein) of the pancreatic ribonuclease chain. It was later found possible to remove several residues on either side of the join without serious detriment to the recombination. Liu, Gutte, Moore and Merrifield (*ibid.*, 5169) have now started at the other end of the chain. Removal of the last six amino-acids (119–124), which include three active site residues, leaves an inactive protein. It will recombine with a synthetic C-terminus, 14 residues long, with revival of activity. The eight superfluous overlapping residues evidently do not get in the way, but when 4 or 5 residues only are detached from the C-terminus, there is evidently some hindrance. An active species can also be produced by mixing S-peptide, the C-terminal peptide and a central core of truncated S-protein.

A special conformational role for the C-terminus emerges from the work of Taniuchi (*ibid.*, 5459), who has pursued the observation that ribonuclease deprived of its last four residues is inactive, but not conformationally disordered. In this form, however, the chain will not refold correctly from the reduced state: evidently random disulphide pairings occur, a vital element of information having been lost with the C-terminus. This supports once more the notion that the chain will not assume its native topology during biosynthesis until it is essentially complete.

TUMOUR VIRUSES

Mutants in the News

from our Cell Biology Correspondent

As the experiments of Burger and Noonan (*Nature*, **228**, 512; 1970) prove, changes in the surface of cells, which can be assayed by the binding of plant agglutinins, seem to play an important part in maintaining a cell in the transformed state. It is as if a tumour virus or other transforming agents cause a permanent exposure of the surface layer containing the agglutinin receptors and as a result the cell cannot stop dividing. If this is the case, mutants of tumour viruses, which have lost the capacity to transform, should fail to cause the exposure of the surface layer in infected cells.

Happily Benjamin and Burger (*Proc. US Nat. Acad. Sci.*, **67**, 929; 1970) report just that result. They have measured the capacity of two agglutinins, wheat germ agglutinin and concanavalin A, to agglutinate Swiss mouse 3T3 cells infected with a mutant polyoma virus NG18. This mutant is one of a suite of host range mutants isolated by Benjamin which I discussed a few weeks ago (*Nature*, **228**, 414; 1970). It can only replicate in Py-3T3 cells, 3T3 cells already transformed by polyoma virus, and it fails to transform either abortively or stably normal hamster or rat cells in culture. As anticipated, 3T3 cells infected with NG18 and three similar mutants are not rendered agglutinable as a result of infection. 3T3 cells infected with wild type polyoma virus, on the other hand, support the replication of the virus and are rendered agglutinable. Experiments with inhibitors of DNA synthesis prove that, in 3T3 cells infected with wild type virus, the membrane change assayed with the agglutinins depends on the induction of DNA synthesis. Further, several experiments with various cell and virus combinations which have been reported by various groups indicate that cellular rather than viral DNA synthesis is required for the exposure of the agglutinin surface layer. But the induction of cellular DNA synthesis, although necessary, is not sufficient to induce the surface change, because NG18 induces cellular DNA synthesis in 3T3 cells but does not render the cells agglutinable. This mutant therefore uncouples the induction of DNA synthesis and the surface change. Either an additional function, which wild type virus can provide but NG18 cannot provide, is also necessary in addition to the induction of DNA synthesis, or the DNA synthesis induced by NG18 differs somehow from that induced by wild type virus.

Clearly, although the mechanism of the induction of the surface change has still to be elucidated, these experiments with NG18 strengthen the suggestion that the exposure of the agglutinin sites is functionally correlated with a loss of growth control. These experiments also draw attention again to the paradox that although host DNA synthesis seems to be necessary for the surface change, the exposure of the agglutinin sites seems to lead to DNA synthesis, for, when resting, untransformed cells are treated with trypsin, the agglutinin sites are exposed and the cell then replicates its DNA and goes through at least one round of mitosis. Presumably in the cell cycle, exposure of the sites leads to DNA synthesis and division, and DNA synthesis is a necessary but not sufficient prerequisite for the subsequent exposure of the agglutinin sites and yet another round of synthesis and division. In this scheme a transforming agent is envisaged as a master switch which ensures that the surface sites are always exposed and the cell is always dividing.

While work with mutants of polyoma virus is progressing rapidly the first temperature sensitive mutants of SV40 are being characterized. Kit *et al.* (*J. Virol.*, **6**, 286; 1970), for example, describe the properties of an SV40 mutant defective in some function, other than the formation of viral capsids, which is required late in the replication cycle of the virus. It is to be hoped that a concerted effort will be made to select mutants of SV40 defective in the function(s) necessary for transformation, because SV40 has one great advantage over polyoma virus for the experimenter; the SV40 genome, unlike the polyoma virus genome, can readily be rescued from a transformed cell.

GENETICS

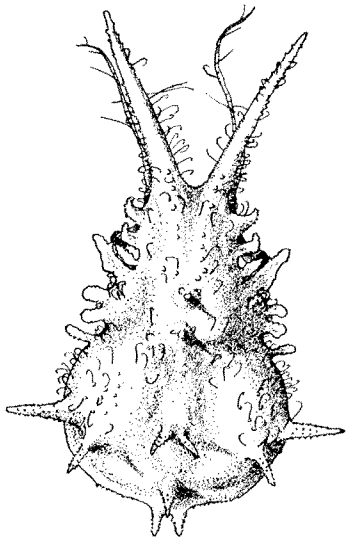
Neurophysiology of *Drosophila*

from a Correspondent

GYNANDROMORPHS, or sexual mosaics, are individuals in which a portion of the body is composed of mutant cells of one sex, in contrast to the rest of the body which is composed of normal cells of the other sex. The division line between normal and mutant parts can occur in various orientations. Mutants of five different genes on the *X* chromosome of the fruit fly, *Drosophila melanogaster*, that cause abnormalities in visual function have been tested by the construction of gynandromorphs in which the mutant part of the

body was male. All of these visual mutants have been found to be autonomous, that is, the mutant eye always functions as mutant tissue, independent of the amount of normal tissue present elsewhere. Thus, at least in this series of mutants, the primary causes of the abnormality in the mutant eyes are within the eye and not elsewhere in the nervous system or brain.

Hotta and Benzer (*Proc. US Nat. Acad. Sci.*, **67**, 1156; 1970) selected mutants of *Drosophila*, carrying the required *X*-linked recessive mutation plus marker genes, and they crossed these flies with females of a strain that often loses the *X* chromosome spontaneously during mitosis. About 10 per cent of the female progeny were found to be mosaics. By counter current distribution, the mutant males were selected to be negatively phototactic and gynandromorphs were selected which had one eye of the normal genotype (that is, positive phototaxis) and the other eye of the mutant type (deficient visual function).



Several of the gynandromorphs were tested for their phototactic response. All the composite flies expressed the visual deficit of the mutant, and parabiosis with a normal half of a fly did not remove the deficit. The response to a short flash of light was measured in these gynandromorphs with the aid of electroretinograms (ERG). The ERG can be tested separately in each eye of a mutant fly. ERGs obtained from the female eye, in which the normal allele is present, were the same as for a normal fly. The ERG recorded from the male eye, in which the recessive mutation was uncovered, was defective in the same way as in a non-mosaic fly. As before, the normal half in parabiosis with the mutant half did not compensate for the defect in the mutant. For flies with heads which had normal and mutant portions, the same result was obtained in every case. Thus, these mutations are clearly autonomous and reside within, or close to, the eye. In six eyes in which the line of mosaic cells occurred within the eye, there seemed to be a high degree of autonomy between those segments of the eye that were normal and those that were deficient. Whatever the genetic defect in these flies, it is clearly expressed only in the mutant parts.

Similar results have been reported by Ikeda and Kaplan (*Proc. US Nat. Acad. Sci.*, **67**, 1480; 1970), who have studied the behavioural phenotype caused by a sex-linked, single gene mutation in gynandromorphs of *Drosophila*. The gene, *hyperkinetic*, controls a leg-shaking action during the administration of ether anaesthesia. In their studies the male tissue of the gynandromorph was hemizygous for *hyperkinetic* whereas the female tissue was heterozygous. The characteristic neural activity caused by the *hyperkinetic* gene can be recorded only in the presumptive male region of the thoracic ganglion. Motor regions of the male side were found to function independently of their counterparts on the female side of the fly and they were unaffected by the genotype of other parts of the body. Thus, expression of the *hyperkinetic* gene is genetically autonomous, and each side of the ganglion is independent of the other. There is also a high correlation between the external genotype and the genotype of underlying neural tissue of the thorax, but the correlation between external and internal genotype is not absolute.

Although these studies are incomplete, a start has been made in the application of the techniques of bacterial genetics to the problems of understanding the role of the brain and nervous system in higher organisms. It will be interesting to observe the results of future studies using mutants with a lesion which can be mapped at a site distant from the sensory organ.

CRUSTACEA

New Spider Crab

Among the benthic invertebrates dredged up some time ago off Rottnest Island, Western Australia, was this strange looking animal which D. J. G. Griffin now describes as a new species of spider crab, *Chlorinoides occidentalis* (*Records of the Australian Museum*, **28**, 65; 1970). The illustration shows the carapace and rostrum of the male holotype which is 17·1 mm long.

TRYPANOSOMIASIS

No Room for Complacency

from a Correspondent

HUMAN trypanosomiasis has been, statistically speaking, a scarce disease in Africa for some years, giving the general impression that it is fully under control. But this is not so; there are probably a million cases of sleeping sickness in the Congo (Kinshasa) at the present time. This gave added interest to the research reported at the annual seminar of the Trypanosomiasis Panel of the Overseas Development Administration, held in London on November 12.

Although contributions covered the whole range of current research on trypanosomes and their tsetse fly vectors, two new developments are particularly worth noting. The first, reported in a series of papers by Dr B. A. Newton, Mr J. K. Burnett and Dr G. A. M. Cross (Molteno Institute, Cambridge), concerns the differing, but constant, DNA from different strains of the same species of trypanosome. Particular attention has been paid to the DNA of the *T. brucei* group, which contains the species causing sleeping sickness, for it may provide information on differential resistance, or sensitivity, to trypanocide drugs.

The approach being considered is that of comparing the metabolism of normal and mutant bloodstream and culture forms, and observing the sequence of metabolic changes during transformation from bloodstream to culture forms. It has been found that different

strains of *T. brucei* differ in the readiness with which they transform, as well as in the ease with which they can be maintained in serial subculture. Current work includes comparing the metabolic patterns of a highly pleomorphic and an apparently monomorphic strain. At the same time it has been observed that naturally occurring and drug-induced mutations which lead to loss or modification of the kinetoplast can only be tolerated in the bloodstream forms of *T. brucei*.

The second new development is the elucidation of the mechanics of animal trypanosomiasis in Latin America. In Venezuela, dairy cattle are protected at present by administering a general treatment against a wide range of diseases, with no discrimination against trypanosomiasis, the epidemiology of which is little known. Now, work reported by Dr M. T. Clarkson (University of Liverpool) has shown that the disease is transmitted by various biting flies, and spread largely because all the cows and their calves are brought in for milking each day, and confined in a small space in conditions which are ideal for transmission of the disease. Further study on the epidemiology of *secodera*, as the disease is called in Latin America, could lead to changes in the organization of the dairy industry which the Food and Agriculture Organization is helping to build up in these countries.

Several gaps in present knowledge also became evident at the seminar. There is a need for much more study of the feeding habits of different species and strains of tsetse. The concentration of "natural history" in the field is being increasingly supplemented by more laboratory studies, such as those of Mr D. A. Turner (London School of Hygiene and Tropical Medicine) and Mr John Brady (Imperial College Field Station). At present it is still a matter of working out the methodology for more detailed studies of visual, olfactory and other reactions which apparently lead different strains to feed on different hosts.

There is also a need for cytogenetic research on tsetse, similar to that done on mosquitoes and *Similium*, which is revealing that strains with different chromosome "architecture" feed on different hosts.

OCEANOGRAPHY

Currents and their Dynamics

from a Correspondent

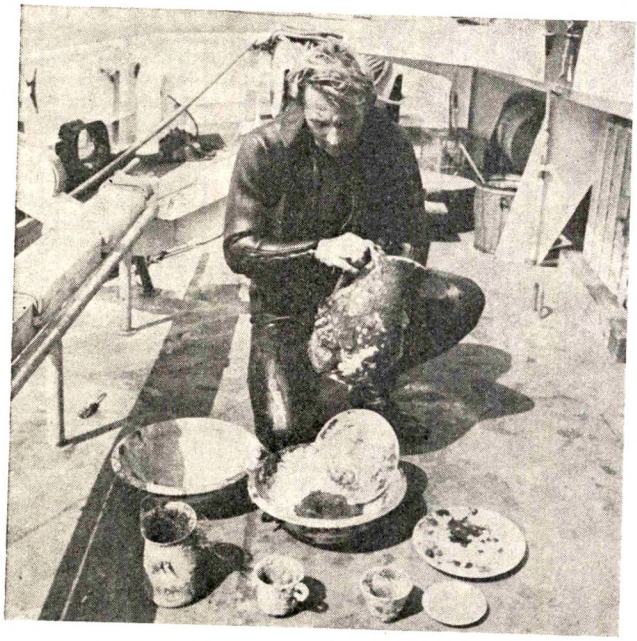
PROBLEMS which have been worrying oceanographers for some time were aired at a discussion meeting on ocean currents at the Royal Society on November 19. In much of the ocean the currents are so variable that it is often hard to detect and thus to calculate correctly the mean current. This difficulty was impressed on oceanographers through some observations made some ten years ago by Dr J. C. Swallow of the National Institute of Oceanography. The general view of ocean circulation then as now was that the strongest currents (10 to 100 cm s^{-1}) were found near the surface and the mean currents in deep water were relatively weak (about 1 cm s^{-1}). By tracking the movements of floats which stay at a pre-determined depth, however, transient currents of around 20 cm s^{-1} were found. These seem to be associated with eddies which are about 100 km across and which cause currents to vary on a timescale of the order of months.

Because the eddies are so strong relative to the mean flow, it is important to know whether they are significant in the dynamics of the mean circulation. The experience of meteorologists may be pertinent. At one time, their models of the circulation of the atmosphere took no account of eddies (cyclones, and the like), until it was discovered that these are so fundamental in the circulation that any model which neglected them was irrelevant. Oceanographers are asking if such might also be the case with the ocean circulation.

Against this background theories of ocean circulation and of variable currents were discussed by Dr A. R. Robinson (Harvard), Professor M. J. Lighthill (Cambridge), Dr A. E. Gill (Cambridge) and Dr P. Welander (Gothenburg). Wind-driven ocean circulation models provide a good qualitative understanding of the principal ocean currrents of the world, like the Gulf Stream and Kuroshio, and why they are found on the western edges of the ocean basins. In present models, estimates of the rate of flow of these great streams depend on friction coefficients, but such coefficients may be inappropriate. For example, they imply that energy is continually being removed from the stream by eddy processes, whereas there are indications that eddies may often give up energy to the stream instead. Theoretical and observational studies of Gulf Stream eddies are in progress, and will throw light on the processes involved, but it also is important to understand the role of eddies in other parts of the ocean.

In the past ten years, technological developments of self-recording, moored current meters and of trackable floats have greatly helped in the direct measurement of currents. The results of such measurements were discussed by Dr N. P. Fofonoff and Dr F. Webster (Woods Hole Oceanographic Institution) and Dr W. J. Gould and Dr J. C. Swallow (National Institute of Oceanography). The energy spectrum shows peaks at semi-diurnal (tidal) periods and inertial periods (a half pendulum day) and also shows a great deal of energy at longer periods. The information about the longer period motion (weeks or more) is less comprehensive because of practical requirements of servicing and maintaining instruments, yet these long-period motions are probably the most significant for the mean circulation.

An afternoon's discussion was aimed towards deciding what could be done observationally to improve the present unsatisfactory situation. Unlike meteorologists, oceanographers do not have a great network of stations at which observations are continually made. They are forced to plan experiments of very limited scale and duration. The significant eddies in the ocean may be small and the timescale large, so that a closely spaced array of measuring devices may be required to be in operation for long periods (for example, about a year). This would require a considerable concentration of resources, and so an international Mid-Ocean Dynamics Experiment (MODE) has been proposed. The discussion centred on the type of information that would be required even to design an effective experiment, or series of experiments. Are the major processes highly intermittent or not? How can the new technologies of current-meter mooring, float-tracking, bottom-pressure recording and of radiometery (surface temperature observation by aircraft or satellite) best be utilized and how can more conventional hydrographic methods and data from



island tide-stations be exploited? The answers to these and other questions will require sophisticated observational programmes. Scientists of the Soviet Union (unfortunately none could be present at the meeting) have an imaginative series of "polygon" experiments in operation, involving the deployment of an antenna-like array of current meters in a 100-mile square of ocean. American and British scientists are planning a PREMODE experiment in which participating groups plan to carry out independent projects in the same area at the same time so that the results will be complementary. The "polygon" and PREMODE experiments signify a new approach to the study of ocean currents and their dynamics. Perhaps there will be fundamental changes in our thinking over the next ten years.

ARCHAEOLOGY

Export Pottery Revealed

from our Geomagnetism Correspondent

THE unmarked wreck of a nineteenth century cargo vessel containing British pottery has been discovered in Delaware Bay between Lewes, Delaware, and Cape May, New Jersey, only thirty-nine feet below the surface. It was found by two ships of the US National Oceanic and Atmospheric Administration (NOAA), the Rude and the Heck, during a routine wire-dragging of the bay in search of submerged navigational hazards. The ship's anchor, of woodstock type weighing about 3,500 pounds and measuring about six feet across the flukes and eight feet along the shank, indicates that the wreck was that of a sea-going vessel, probably British.

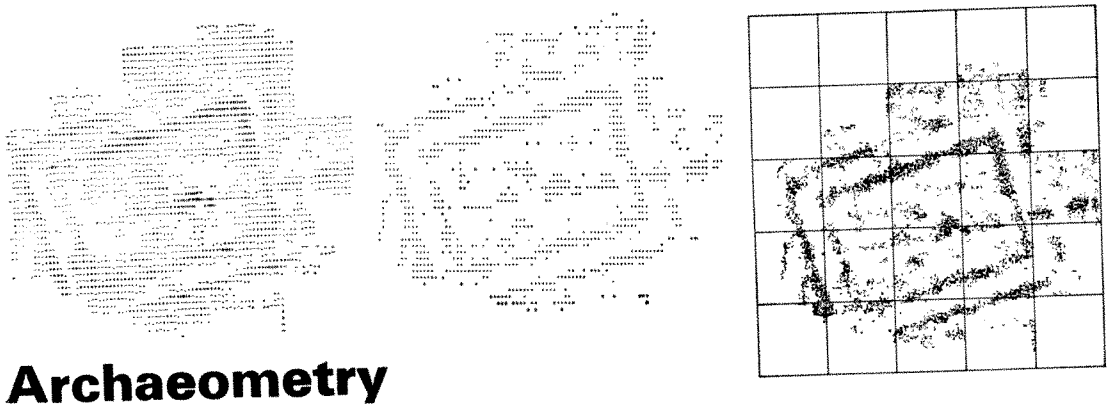
Some of the pottery found in the wreck. (Photograph by courtesy of NOAA.)

Scuba divers found the wreck laid open on the bottom. Most of the cargo was embedded in coral and silt; but thousands of pieces of British-made pottery, neatly packed, were exposed in a pile about ten feet high and thirty feet across. According to Jefferson Miller, curator of ceramic history at the Smithsonian Institution's National Museum of History and Technology, the white, undecorated pottery found in the wreck was manufactured from 1850 onwards, but no later than 1876. He identified it as the products of Powell and Bishop, a Hanley, Staffordshire, pottery firm which operated between 1876 and 1878; J. W. Pankhurst and Co., also of Hanley, 1850–82; and W. and E. Corn of Longport, Staffordshire, about 1864–94.

Most of the chinaware was English "ironstone", a heavy durable earthenware intended for everyday use. One exception was a hand-enamelled cup with simple multi-coloured flowers manufactured between 1850 and 1900. The cargo also included pitchers and washbowls.

SUPERFLUIDITY

Flow in Solids



by our Solid State Physics Correspondent

THE speculation by A. J. Leggett (*Phys. Rev. Lett.*, **25**, 1543; 1970) that it may be possible to observe in certain solids a mild form of superfluidity is not as far fetched as it might seem. There is no suggestion, of course, that a solid can exhibit the astonishing flow properties which allow liquid helium-4 to pass through holes so minute that even many gases are barred from entry. The identity of a solid hinges, after all, on its rigidity and atomic order. But what Leggett is proposing is that certain insulating solids may be in a sufficiently similar quantum state to that in superfluid helium to show a diminution in the moment of inertia of the solid which can be detected in an experiment.

The onset of superfluidity in liquid helium is associated with the Bose condensation of the fluid at about 2·2 K. A recent suggestion that a finite fraction of the atoms in a Bose solid may reside in the zero momentum state alerted Leggett to the possibility that a milder strain of the same superfluid condition may also manifest itself in these solids, and he has calculated the lower limit of what he calls the superfluid fraction in such a solid. If all the atoms are localized at given atomic sites, superfluidity cannot occur, but if atoms can swap places in the lattice, the solid should exhibit some drop in its rotational inertia from the classical value. This swapping is quite in keeping with the concept of a solid, providing the atomic sites themselves are essentially fixed.

Leggett suggests that the most favourable material in which to observe the effect should be solid helium, although practical difficulties may mean that other substances are more suitable. He suggests two experiments in which the superfluid property could manifest itself. If the solid is formed into the shape of a ring, the moment of inertia of the ring should be below that expected in a classical calculation. This could be tested in some dynamic experiment. The sample would have to be retained at a very low temperature throughout. A second test would be to rotate the solid and bring it into impact with some other body. If the solid had the superfluid property there should be some residual angular momentum. Leggett points out that it is not surprising that nobody has stumbled on the effect by accident because the conditions required to observe it are quite exacting.

Computer-produced diagrams from measurements taken by a magnetic detector, clearly showing the outline of archaic remains beneath modern topsoil at a Roman site in the Rhineland.

Archaeometry

Managing Editors
E. T. HALL and M. J. AITKEN
Editor MRS. J. REID

Archaeometry is the only journal devoted to the applications of the natural sciences to archaeology. Physics and chemistry are increasingly involved in archaeological studies and *Archaeometry* assists the archaeologist in his difficult task of keeping up-to-date with these developments. The journal includes work on dating methods, locating devices, archaeomagnetic measurements, and analyses of coins and other artefacts.

Archaeometry began in 1958 as the bulletin of the Oxford University Research Laboratory for Archaeology and the History of Art. Now, while it is still based at the Laboratory, reports come from contributors in all parts of the world.

Two issues are published each year. Annual subscription £3 ($9.50 in the USA).

An Ecological Approach to Acanthocephalan Physiology

D. W. T. CROMPTON

Acanthocephalan worms are parasitic throughout their life cycles; they develop in the tissues of arthropods and reach maturity in the intestines of vertebrates. This monograph is a study of their physiology, and how it relates to the physical and biotic factors in their environments. It will interest teachers and research workers in parasitology and invertebrate physiology.

Hausdorff Measures

C. A. ROGERS

The first general account of Hausdorff measures, a branch of pure mathematics which has many applications in other areas of mathematics. Chapter 1 introduces measure theory, paying special attention to non-σ-finite measures. The second chapter develops the most general aspects of the theory of Hausdorff measures, and the third gives a general survey of the applications. **£3.80 net**

CAMBRIDGE UNIVERSITY PRESS

Differential Forms on Electromagnetic Networks

J. W. Lynn, MSc, PhD, CEng, MIEE, D. R. Sengupta, BSc, BTech, PhD, and M. V. Balasubramanian, MSc

This book is unique in the field of engineering, presenting a concise description of the application of the powerful methods of differential forms, to electromagnetic networks. Topological relationships between lumped circuits and vectors of the associated electromagnetic fields, form the main part of this book.

Photochemistry

Dr. R. P. Wayne, MA, PhD(Cantab) MA(Oxon)

Undergraduates and non-specialist research students will find this a stimulating book which unifies and gives relevance to several apparently disparate aspects of physical chemistry. To bring out the underlying physical principles, the subject is developed in terms of the fates that can befall excited species. Many illustrative examples are given, which introduces the reader to the photochemistry of normal and polluted atmospheres, photosynthesis, vision, photography and other important subjects.

A Simplified Approach to Solid State Physics

M. N. Rudden, BSc, PhD, AInstP, and J. Wilson, BSc, PhD, AInstP

This book provides a broad survey of some of the more important concepts of solid-state physics and should be suitable for first-year university or technical college students. The approach throughout is essentially qualitative and the aim of the authors is to establish the fundamentals of the subject in as easy a manner as possible. To this aim, frequent reference is made to experimental evidence in support of the theoretical concepts.

Stereographic Projections of the Cubic and Closed Packed Hexagonal Lattice

A. R. Booth, BMet, PhD, GradIM, and A. T. Davenport, MMet, PhD

Presented in this volume are 20 stereographic projections of the cubic and close packed hexagonal lattices produced by a computer program. The projections are printed on transparent tracing paper and designed to be used with the 30 cm. equatorial stereographic net (Wulff net) supplied at the back. For this reason the volume has a spiral binding to allow easy removal of the projections for their use with the net. It is thought that this volume will be of great use to all crystallographers.

Generation of Radio Waves in Pulsars

by
F. G. SMITH

University of Manchester,
Nuffield Radio Astronomy Laboratories,
Jodrell Bank

Pulsars generate radio waves by an unknown process which gives the highest volume emissivity known in astrophysics. The radiation forms a beam the width and polarization of which are independent of frequency. This article assembles the observational facts which any theory of emission must explain.

THE Crab Nebula pulsar, NP 0532, is the only pulsar of the fifty-five known in which any radiation has been detected outside the radio range of wavelengths. In this article I shall set out the requirements of a theory to explain the radio emission, concerning which a great deal of experimental detail is known; but it is proper to ask first whether the same mechanism is responsible for the X-ray, optical, infrared and radio radiation of NP 0532. The spectrum of this radiation is shown in Fig. 1, including the long wavelength radiation previously ascribed to a continuously radiating discrete source by Hewish and Okoye[1,2].

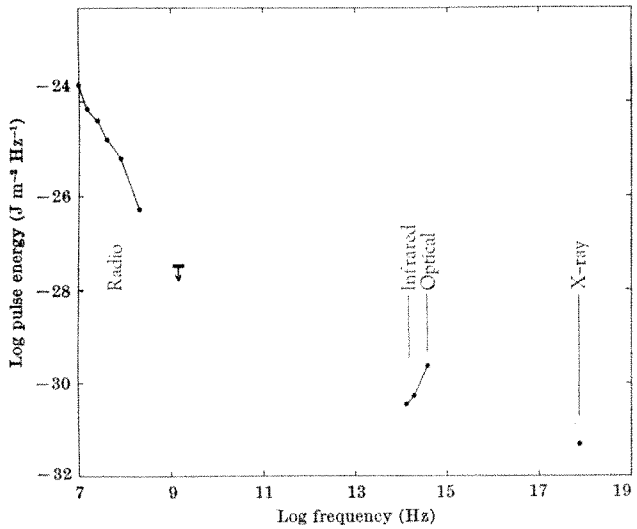

Fig. 1. Spectrum of the radiation from NP 0532. The points at frequencies below 100 MHz refer to the discrete source discussed by Bridle[2]; other points are taken from Bradt *et al.*[1].

The Crab Nebula itself radiates a continuous spectrum throughout this range by the synchrotron process, but it seems unlikely that the pulsar radiation has a similar continuous spectrum. In particular, there seems to be a minimum between the radio and the infrared, which has been interpreted by Shklovsky[3] as a boundary between two different radiation processes. There may also be differences between the radio and optical pulses concerning their polarization[4] and variations in intensity[5]. It is therefore assumed that no single process operates continuously over the whole spectrum; nevertheless there is close similarity between the integrated pulse profiles at all wavelengths, which surely indicates a common point of origin and a common beaming mechanism.

The radio pulses from a typical pulsar have the following properties. (1) A precise periodicity. The pulses occur during a time interval of between 1 and 4 per cent of the period. The duration of this "pulse window" bears a remarkably constant ratio to the period, since the periods range over a ratio of 100:1. (2) The pulses are often considerably shorter than the pulse window. For those pulsars where individual pulses can be observed, their duration is between $\frac{1}{2}$ and 3 per cent of the period. (3) Multiple pulses can occur. More than one pulse can be seen within a single pulse window. In CP 1133 pulses appear substantially independently in two overlapping regions of the window (Fig. 2). In AP 2015 and several other pulsars two or three pulses may appear in a single window, with a well defined time interval between them[6]. (4) Pulses vary greatly in power, but at least a factor of 10 within a few pulses or even between successive pulses[7]. (5) There are trains of related pulses; successive pulse windows may contain pulses which are recognizably similar in strength, width or structure. Successions of up to 10 or more related pulses are observed in some pulsars, such as CP 1919[8]. (6) Successive appearances of similar pulses drift earlier in the pulse window at a rate typical of individual pulsars[6]. The drift may carry an identifiable pulse from one window to another some hundred or so periods later, as in MP 0031[9]. (7) The shape of pulses is variable. Symmetrical pulses, like Gaussian functions, are observed in many pulsars; others have more complex and variable shapes of pulse which might be described as the sum of several Gaussian curves. Fine structure, down to 0·1 per cent of the period, has been observed, as for example in CP 0950[10]. (8) Individual pulses, and especially those that have a simple Gaussian shape, are highly polarized[11]. The polarization is in general elliptical, with an axial ratio and a direction of major axis which varies through the pulse. The polarization often reaches 100 per cent, including occasionally a completely circular polarization[12]. Fig. 3 shows some pulses from CP 0328 recorded with a polarimeter at 408 MHz, in which the measured fractional polarization $(V^2+Q^2+U^2)^{\frac{1}{2}}/I$ varies generally from 0·5 to 1·0. Separate pulse components may have quite different polarizations, as seen for CP 1133 in Fig. 2. (9) The sum of some hundreds of pulses, superposed by adding successive periods, forms an integrated profile which is characteristic of an individual pulsar. The profile

usually has a single smooth maximum, although it may contain two or more peaks[13]. (10) The Stokes parameters of successive pulses can also be added to obtain an average polarization. This is usually predominantly plane, for the circular components of different pulses tend to cancel. The position angle of the integrated plane component rotates through the pulse window by an angle between 0° and 180° (refs. 12, 14). (11) The spectrum of the radio pulse extends for some pulsars at least from 40 MHz to 4,995 MHz, but few points are available to define the average spectra of most pulsars. At frequencies greater than 300 MHz the average flux density of most pulsars decreases rapidly, at least as the square of the frequency. Some pulsars have a flatter spectrum at lower frequencies; CP 0328 seems to have a broad peak at about 500 MHz, witb a decrease below 300 MHz. (12) The shape of the integrated profiles of most pulsars is markedly insensitive to frequency, apart from a lengthening at lower frequencies due to interstellar scintillation[15,16]. The relative heights of the several peaks in the profile of AP 1237+25 are, however, different at frequencies an octave apart[17], while the separation of the double peak of CP 1133 varies roughly as the fourth root of the frequency[18]. (13) Detailed comparison of individual pulses recorded simultaneously at widely separated frequencies is difficult, largely because of the effects of interstellar scintillation. Fig. 4 shows a new recording of individual pulses of

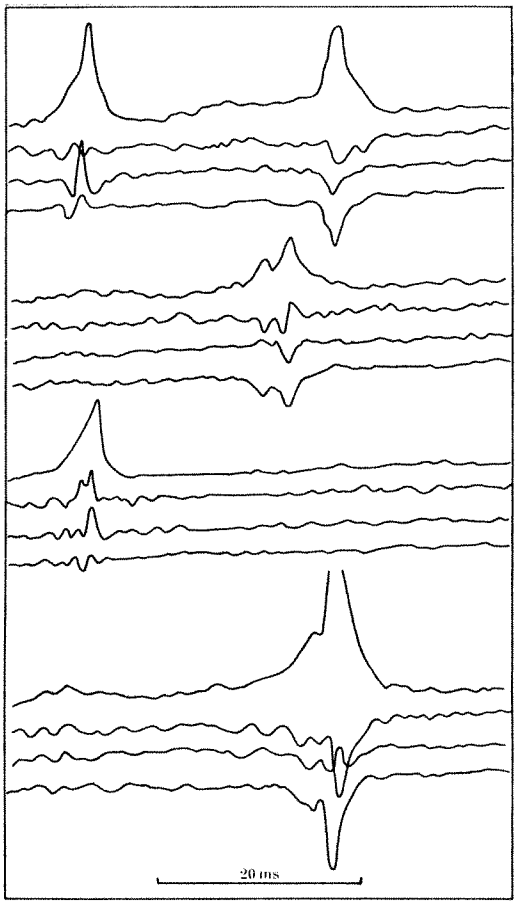

Fig. 2. Four individual pulses from CP 1133, recorded with a polarimeter at 408 MHz. For each pulse the Stokes parameters I, V, Q, U are recorded. The pulses tend to occur at two separate times about 20 ms apart; the sum of many pulses produces the well known double peaked profile.

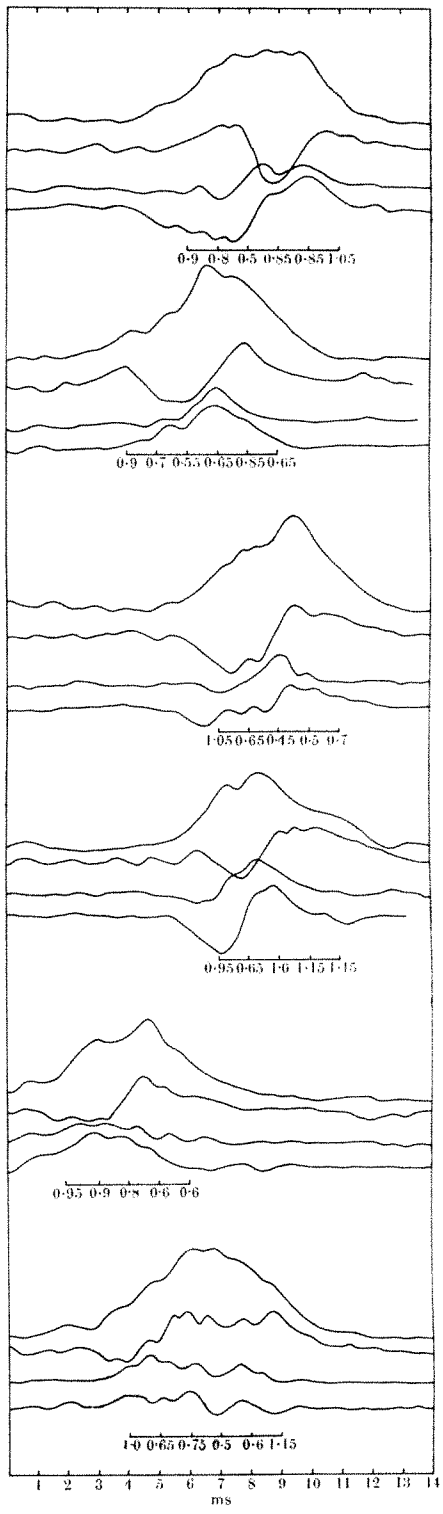

Fig. 3. Six pulses from CP 0328, recorded with a polarimeter at 408 MHz. For each pulse the Stokes parameters I, V, Q, U are recorded. The fractional polarization $(Q^2+U^2+V^2)^{\frac{1}{2}}/I$ is shown at intervals of 1 ms through each pulse.

CP 0328, at frequencies of 408 MHz and 240 MHz. Only the I and V components are shown, because differences in the linear components are to be attributed to Faraday rotation in interstellar space[19]. Within the noise level of the recordings the pulse shapes are seen to be identical. (14) Within several months the intensity of some pulsars changes by considerable factors, as measured on a single

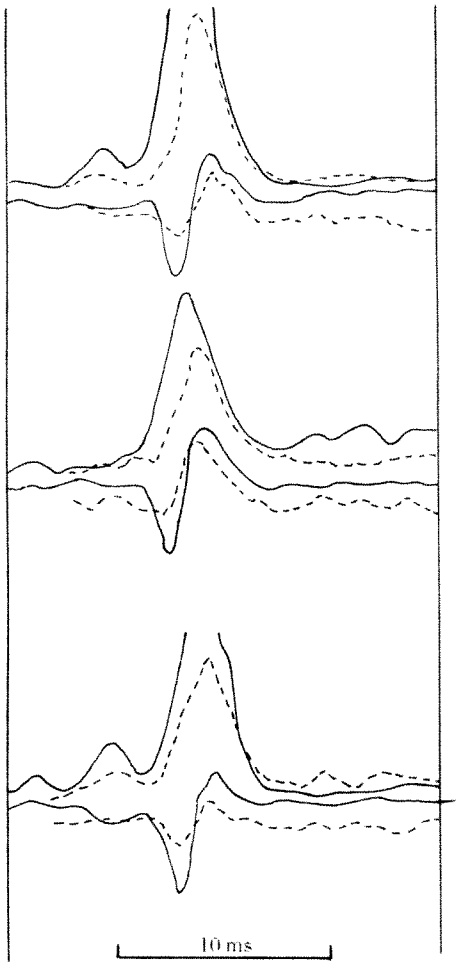

Fig. 4. Three pulses from CP 0328, recorded both at 408 MHz and 240 MHz. The upper traces record intensity (I) and the lower traces record the circularly polarized component (V). Full line—408 MHz (bandwidth 330 kHz); broken line—240 MHz (bandwidth 100 kHz).

frequency[20]. It is not yet clear whether this variation affects the whole radio spectrum simultaneously.

The extent and detail of this information are so great that one might expect the mechanism of the radiation to be already obvious. There is general agreement that the pulses are due to a beaming effect in a rotating source[21,22], and it was natural to suggest a mechanism similar to synchrotron radiation[23,11]. The problems in such suggestions concern the very high intensity, the spectrum, the high polarization, and the frequency invariance of the polarization and beamwidth.

High Intensity

From the precise periodic reappearance of the pulse window, we can deduce that the source of the radiation is attached to a rotating neutron star, presumably by magnetic field lines. It therefore lies within the distance $c\omega^{-1}$, where ω is the angular velocity of the star, and its radius r is less than $c\omega^{-1}$, which is called the radius of the "velocity of light cylinder". The narrowness of the pulse in relation to the period suggests that the source extends over only a very small range of longitude, probably a distance less than $0{\cdot}02\ c\omega^{-1}$. It may, of course, be more extended radially. I shall assume that the source is roughly spherical, with radius $0{\cdot}05\ c\omega^{-1}$, and calculate on this basis the volume emissivity, using as examples NP 0532 and CP 0328.

A further assumption must be made about the directional properties of the source, which may radiate preferentially in a plane containing the observer; it is also possible that the observed peak pulse intensity is enhanced by a relativistic beaming effect[13]. I shall calculate first the pulsed flux density at the surface of the source, and then the volume emissivity in terms of the power averaged over one period. Again it is necessary to make an assumption about the total solid angle of sky illuminated by the source; here I shall assume arbitrarily that the fan beam of the source sweeps across a solid angle of one tenth of 4π. Thus if the distance of the source is D, the peak flux density is S_p, the equivalent pulse width is w, and the period P, the peak flux density S_{ps} at the source, is given by

$$S_{ps} = S_p \left(\frac{D}{r}\right)^2$$

and the volume emissivity Q is given by

$$Q = 0{\cdot}1\ \frac{3S_{ps}}{r} \cdot \frac{w}{P}$$

The total power flux and the total volume emissivity have been calculated by using a bandwidth factor of 200 MHz; this factor is poorly determined at this time.

The electric field E_s in the radiation at the surface of the source is given by $E_s^2 = 377\ Q_{\text{total}}$, using SI units. The distance of CP 0328 is taken to be 1 kpc, and that of NP 0532 as 2 kpc. Peak values of flux density at 100 MHz for NP 0532[24], and at 400 MHz for CP 0328[25], are approximate, because little account has been taken of interstellar scintillation in observations so far.

Coherent Electron Motion and Synchrotron Radiation

In spite of the crudity of the assumptions which have been made about the size of the source, there seems no escape from the very high values of emissivity and flux density in Table 1, even though the rate of power generation per unit volume in NP 0532 is comparable with that in the core of a nuclear power generator. Some reduction may be allowed if the beaming is a relativistic effect of the rapid orbiting motion of the source[13], but this only reduces the volume emissivity by a factor less than 100, and the field strength by a factor less than 10. The brightness temperature of NP 0532, using the tabulated value of S_{ps}, reaches 2×10^{28} K, which exceeds the brightness temperature of an electron gas with energy $\varepsilon\ m_0c^2$ by a factor $4 \times 10^{18}\ \varepsilon^{-1}$. Evidently, a coherent electron motion is involved. Further, the high field strength E_s, observed for radiation with wavelength of order 1 m, ensures that all electrons acquire a relativistic energy, such that $\varepsilon \gg 1$, merely by the existence of the radiation field. The conditions of radiation therefore must involve the coherent motion of high-energy electrons, with the attendant difficulties of non-linear theories of wave propagation and interaction.

Table 1. PARAMETERS OF TWO PULSARS

	S_p ($Wm^{-2}Hz^{-1}$)	S_{ps} ($Wm^{-2}Hz^{-1}$)	S_{total} (Wm^{-2})	E_s (Vm^{-1})	Q ($Wm^{-3}Hz^{-1}$)	Q_{total} (Wm^{-3})
NP 0532	10^{-23}	6×10^{6}	$1{\cdot}2 \times 10^{15}$	7×10^{8}	$0{\cdot}8$	$1{\cdot}6 \times 10^{6}$
CP 0328	10^{-24}	3×10^{2}	6×10^{10}	5×10^{6}	2×10^{-6}	400

Early attempts to explain the radio emission were based on the synchrotron mechanism. It was noted that an organized stream of electrons would radiate a beam the angular width of which might correspond to the pulse

width[23], and it was later found that the polarization varied across individual pulses in a way which resembles that of synchrotron radiation[11]. The combination of the independence of pulse width on frequency, and of the high degree of polarization, however, now makes this theory unacceptable. Indeed, no simple radiation process which can produce these two properties together has yet been suggested. A simple geometrical explanation of the beam is required, as opposed to an electrodynamic radiation process. For example, it has been suggested[14] that electrons are constrained to flow along a bundle of magnetic field lines, the directions of which define the beam. In common with other synchrotron explanations, this theory cannot, however, explain the existence of a high degree of polarization over a wide range of frequencies. A simple geometrical explanation of the beam is required, in which the angular width and the polarization distribution are determined by factors which are independent of wavelength.

Wave Amplification

A more promising line of theory ascribes the high intensities to a wave amplification process in which plasma waves are coupled to the electromagnetic field[26]. Here a high degree of polarization is to be expected, for it only requires one polarized mode of propagation to be amplified preferentially for almost complete polarization to be obtained from an initially unpolarized wave. The coupling is high at frequencies near the gyro-frequency, and for an assembly of highly relativistic particles it seems possible for coupling to extend over a considerable range of frequencies. It would, of course, be necessary to show that the polarization is independent of frequency over a wide range. This kind of theory does not of itself explain the beaming of the radiation.

The narrow beam of radiation may conceivably be produced in an unpolarized or partially polarized state, by some mechanism which gives a beam width independent of frequency, and with a subsequent amplification by interaction with plasma waves. The original beam might then be defined by the flow of electrons along magnetic field lines[14]. Then the polarization induced by the plasma waves must follow the complex patterns which are observed, and which now represent differences over small angular widths in the relative amplification of different modes. These processes must produce a polarization which does not depend on frequency; this may raise serious difficulties, since the width of any small scale angular dependence seems necessarily to involve a relation between wave frequency and plasma or gyro frequencies.

The only other suggestions for the formation of a narrow beam depend on the high relativistic velocity of the emitting region of the pulsar atmosphere, which is now required to be located close to the "velocity of light cylinder" and which is nevertheless coupled tightly to the pulsar through the magnetic field of the pulsar. If it is thought that the relativistic velocity is itself the cause of the radiation[27], then the difficulties of beamwidth and polarization must again be contended with. If, on the other hand, the relativistic velocity is considered to be producing a beaming effect in a source which is radiating more nearly isotropically[13], then a purely geometrical condition for beamwidth has been found and the radiation mechanism is easier to understand. In this latter case the wave amplification theory must amplify selectively a wave which is generally elliptically polarized, with an axial ratio that varies only slowly with wave direction; for example, as the cosine of the angle between the field and wave directions. The emergent polarization would then vary with direction roughly as does the polarization radiation at the gyro frequency (cyclotron radiation). An amplification process, however, might be expected to select a purely circular or purely linear mode, and it remains to be shown how a plasma can radiate or amplify with a suitable angular distribution of elliptical polarization.

Spectrum and Fluctuations

On any theory the source of the radiation must contain a high concentration of energy in the form of coherent plasma oscillations; probably these will be concentrated at the gyro frequency. The source is located within a region defined by the pulse window. Within this window the spectrum of the radiation from all locations is everywhere wide, and everywhere nearly but not quite the same, as seen by the small variations in shape of the pulse window. The field direction, which must define the state of polarization, varies across the region so that its aspect appears to the observer to change smoothly by an angle between zero and 180° for different pulsars.

The excitation of small parts of the region varies rapidly, usually within a single rotation period. The excitation may travel from one part of the region to another, sometimes with an organized motion which carries it in the forward direction of rotation. An identifiable excitation can travel right through the region and persist for a complete circuit of the pulsar, reappearing in the emitting region. Since the magnetic field in the emitting region appears to be stable, it seems that this excitation must be in the form of a travelling concentration of plasma waves.

The description of the phenomena of the radio emission, and the immediate deductions about the nature of the source, naturally represent a selection of those observations and theories which seem to me at this time to be the most important and deserving of attention. The references could not be made comprehensive, and apologies are due to many authors whose work may have been touched on without due acknowledgement.

Structure and Activity of Acetylcholine

by
W. H. BEERS
E. REICH
The Rockefeller University,
New York,
New York 10021

Conformational analysis of several agonists and antagonists can be used as a basis for the definition of structural parameters necessary for the range of activity of acetylcholine.

THE classical experiments of Dale[1] established that the pharmacological actions of acetylcholine (Ach) outside the central nervous system could be divided into two categories, nicotinic and muscarinic, each defined by the effects of characteristic agonists and antagonists and based on the actions of nicotine and muscarine. These two pharmacological classes can also be separated on physiological and anatomical grounds. The nicotinic transmission sites are predominantly at neuromuscular junctions and in autonomic ganglia, whereas the muscarinic sites are mostly in parasympathetic target organs. More recently some muscarinic synapses have also been described in autonomic ganglia[2]. There have been numerous attempts to explain in structural terms the different, non-overlapping specificities of drugs representing each class, and to identify the properties of acetylcholine which account for its activity at both types of junction. According to Chothia[3], the nicotinic and muscarinic receptors are considered to interact respectively with two different sides of acetylcholine when the transmitter is in a conformation which is observed in one crystal structure. We offer an alternative proposal.

We have examined Dreiding and CPK space-filling models of compounds which affect nicotinic and muscarinic junctions and have attempted to identify common structural features in each series. We have focused attention on molecules containing elements of structural rigidity because rigidity restricts conformational options and reduces the ambiguity in stereochemical assignments for functional groups. Our findings indicate that the nicotinic and muscarinic specificities of cholinergic receptors can be understood in terms of interactions based on two different combinations of functional groups in the transmitter molecule. Within each category common structural features are shared by agonists and antagonists. This is reassuring, for they are thought to compete for the same receptor site[4-6]. In addition, there are some molecular differences between agonists and antagonists which may be correlated with activity.

Nicotinic Agents

We propose that the specific binding of nicotinic agents to their receptor is mediated by two elements: (1) a coulombic interaction involving the alkylammonium moiety, and (2) a hydrogen bond which depends on an acceptor group in the drug and is formed approximately 5·9 Å from the centre of the positive charge (Fig. 1). This structural pattern is common to a family of fully or partly rigid molecules that are active as agonists or antagonists only at nicotinic junctions; in acetylcholine the corresponding distance can be reached only if the carbonyl oxygen serves as the H-bond acceptor.

The alkaloid cytisine (Fig. 2) is pharmacologically identical and virtually equipotent with nicotine[7]. The fused ring system makes cytisine a rigid molecule in which conformational uncertainty is restricted to the six-membered ring containing the secondary amino group. We assume that this six-membered ring exists predominantly in the more stable chair form. In this conformation the centre of the positive charge is 5·9 Å from the proposed H-bond acceptor site on the amide oxygen.

Nicotine, the prototype agonist at autonomic ganglia and neuromuscular junctions, is not as rigid as cytisine, but does not have the conformational freedom which might be implied by a non-space-filling representation of its structure. The possible conformations are restricted by steric interactions between protons on the pyrrolidine and pyridine rings. From the crystal structure[8], magnetic resonance and dipole moment data[9], and from space-filling models, the conformation shown in Fig. 3 seems to be the most likely. In this the centre of the charge is 5·9 Å from the centre of the van der Waals surface of the pyridine nitrogen (the proposed H-bond acceptor site).

Two points should be noted about nicotine. It contains an asymmetric carbon atom and therefore exists in two optically active forms; *l*-form occurs naturally in tobacco. The non-superimposable mirror image—the *d*-form—should retain the distance between the charged nitrogen and the free electron pair on the pyridine nitrogen. If these two elements are indeed the determinants of nicotinic specificity, *d* and *l*-nicotine should have identical properties. In fact, there is no pronounced difference between them. The estimates for the relative potencies of the two isomers range from 1 (ref. 10) to 8 (ref. 11).

Because of the presence of the asymmetric carbon atom, and because all the atoms of nicotine are incorporated into ring systems, the *d* and *l*-isomers, even at first glance, seem to be quite different. Closer examination reveals that if one superimposes the planes in *d* and *l*-nicotine which are formed by the cationic centre, the unshared electron pair and the centre of the pyridine nitrogen, then only one additional atom (the carbon

para to the pyridine nitrogen) is spatially homologous in the two enantiomers. Thus, if the charge and pyridine nitrogen are important for activity of the molecule, the similar potency of *d* and *l*-nicotine argues strongly against any direct contribution from the carbon skeleton. We conclude that the role of the carbon skeleton is simply to provide proper stereochemical localization of the functional groups which determine specificity.

Strychnine and Other Antagonists

Strychnine (Fig. 4) is best known as a powerful convulsant which acts directly on the central nervous system. In isolated neuromuscular preparations[12] and in ganglia[13], however, it behaves as an antagonist of acetylcholine. Strychnine has a tertiary amino nitrogen which is positively charged at neutral *p*H; it contains in addition an amide grouping and an ether oxygen. Quaternization of the nitrogen yields N-methylstrychnine with enhanced curare-like activity[14]. N-Methylstrychnidine

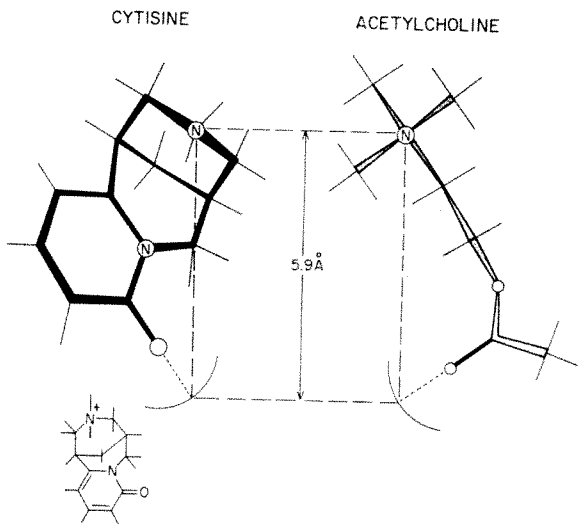

Fig. 2. Cytisine, see text.

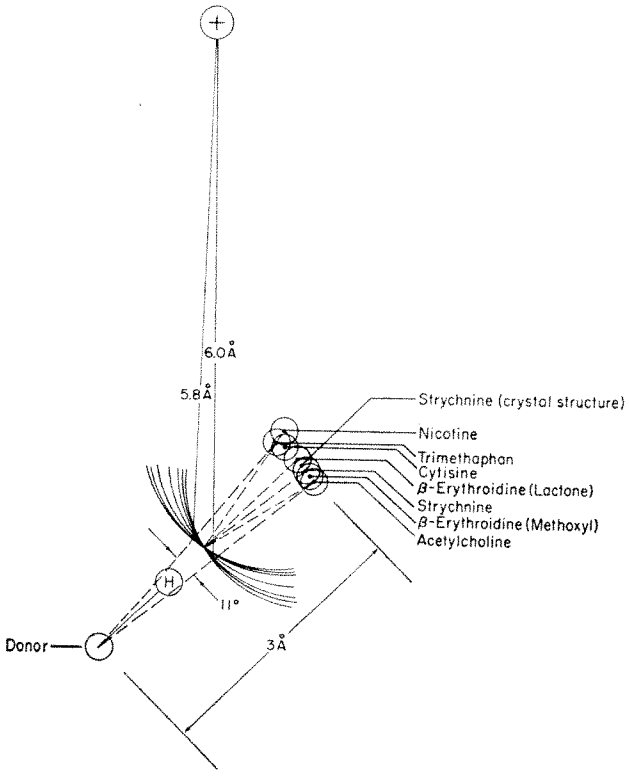

Fig. 1. Composite diagram of nicotinic agonists and antagonists, illustrating the range of H-bonding geometry envisaged for some of the rigid and partly rigid nicotinic agents considered in the text. After a preliminary study of the individual drugs had established that the separation of the proposed H-bond acceptor, and a point on the van der Waals the molecules were compared as follows. The structure of each molecule was drawn to scale in a plane defined by the charge centre, the nucleus of the proposed H-bond acceptor, and a point on the van der Waals surface of the acceptor. The point selected for this can be considered the "centre" of the van der Waals surface; it is the point of intersection of the van der Waals surface and the radius that is in the plane formed by the covalent bonds to the acceptor atom and which bisects the angle between these bonds. When carbonyl oxygens are envisaged as H-bond acceptors, the radius that intersects the centre of the van der Waals surface is obtained by extending the line that represents the C=O bond. The arcs in Figs 1–6 represent the intersection of the van der Waals surfaces of the respective acceptor atoms with the plane of the diagram. For each molecule a point on this arc was located corresponding to a distance 5·9 Å from the charge centre. The different molecules were then compared by superimposing these points and the charge centres, and the positions of the respective nuclei of H-bond acceptors were recorded. Assuming that the distance between the H-bond donor and acceptor nuclei is 3 Å, and that the donor is positioned as shown, the distortion of the proposed H-bond is less than ±6° for the drugs which were examined.

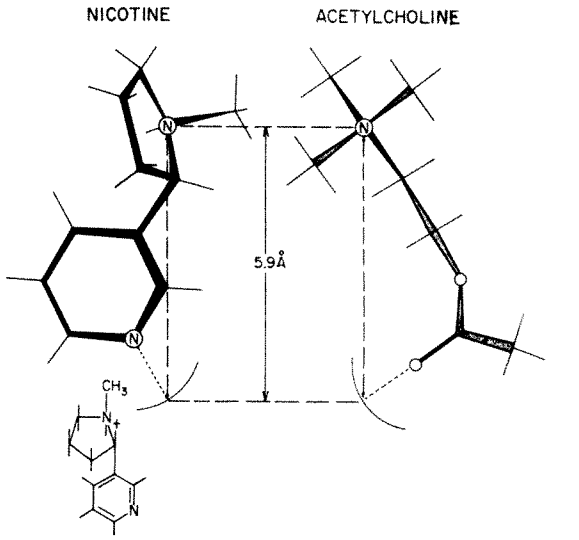

Fig. 3. Nicotine. The *l*-enantiomer is shown here. The distance from the centre of the charged pyrrolidine nitrogen to the centre of the van der Waals surface of the pyridine nitrogen is 5·9 Å.

is identical with methylstrychnine, except that the amide oxygen is no longer present; however, N-methylstrychnidine remains a potent curariform agent[14]. Thus the amide oxygen cannot be responsible for this activity.

The distance from the centre of the charged nitrogen to the van der Waals surface of the ether oxygen can be estimated with some confidence because of the rigidity imposed by the structure of the alkaloid. From model building this distance is estimated to be 5·9 Å. This value is in satisfactory agreement with both the results of X-ray analysis of the strychnine crystal structure[15] and the distance between the homologous functional groups in nicotine and cytisine.

Beta-erythroidine (Fig. 5) is a potent nicotinic antagonist, and has, like strychnine, a rigid caged structure that limits the conformational freedom of individual functional groups. Erythroidine contains a tertiary amino nitrogen which is positively charged at physio-

logical *p*H, and three oxygen atoms, all of which can act as H-bond acceptors. For two of the oxygen atoms the distance from the potential H-bonds to the centre of the positive charge is 5·9 Å. The potent nicotinic antagonism of erythroidine could in part result from this aspect of its structure, which provides two potential binding combinations which can mediate stereochemically satisfactory interactions with the receptor. This possibility is supported by the fact that removal of the methoxyl group or opening of the lactone ring reduces the potency of erythroidine, but only by a factor of 2 or 3 (ref. 16).

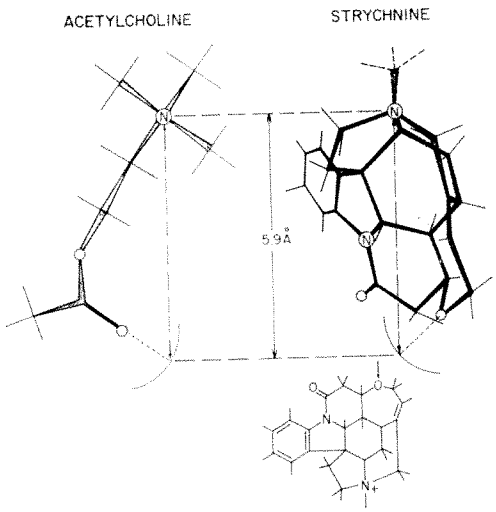

Fig. 4. Strychnine, see text.

Trimethaphan (Fig. 6) is another nicotinic antagonist in which the proposed structural determinants of specificity are situated in a rigid ring system. In this case the cationic grouping is a sulphonium ion, and an H-bond can be formed at a distance of 5·9 Å from the centre of the positive charge; the ureido oxygen atom is visualized as the presumptive H-bond acceptor.

Some other nicotinic agents should also be considered. Although their conformations are not fixed by rigid caged structures comparable with those which occur in strychnine and erythroidine, the distribution of functional groups in the potent nicotinic agents lobeline, benzoquinonium and muscarone would readily permit these drugs to interact with the receptor in the manner proposed for Ach.

The biological activity of a family of substituted toxiferines supports the postulated formation of an H-bond at the Ach binding site on the nicotinic receptor. It is generally accepted that the two cationic centres of toxiferines interact electrostatically with the anionic groupings of neighbouring Ach binding sites. It is therefore interesting that the stepwise addition of two hydroxyl groups onto the toxiferine nucleus is associated with successive two to three-fold increases in activity[17]. These hydroxyl groups are free to rotate, and to assume a position which permits the oxygen to act as an H-bond acceptor 5·9 Å from the charge centre. This type of interaction at the Ach binding site could account for the increasing potency which accompanies progressive hydroxylation of the toxiferine nucleus.

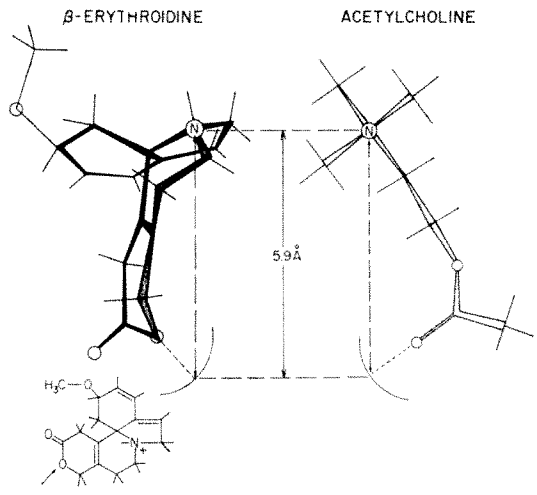

Fig. 5. Here the distance between the H-bonding site on the lactone oxygen and charge centre is shown. A separation of 5·9 Å between the charge centre and an H-bonding site on the methyl ether oxygen is also possible.

Like toxiferine, *d*-tubocurarine is considered to complex primarily with the anionic components of adjacent Ach binding sites. The tubocurarine molecule contains numerous oxygen atoms and its crystal structure (unpublished work of T. D. Sakore, S. S. Tavale and H. M. Sobell) indicates that two of these can serve as H-bond acceptors at positions that are stereochemically compatible with those proposed for the other nicotinic agents.

The limited pharmacological knowledge of the alkaloid anagyrine suggests that this compound too is a nicotinic agonist[18]. Anagyrine is a derivative of cytisine and is identical with it in terms of the relationship between the charge centre and H-bond acceptor.

The nicotinic agents we have considered differ markedly in structure and in physico-chemical properties, but they have one set of common structural features: a cationic centre and a potential H-bond acceptor 5·9 Å apart. Thus the Ach binding site is visualized to contain

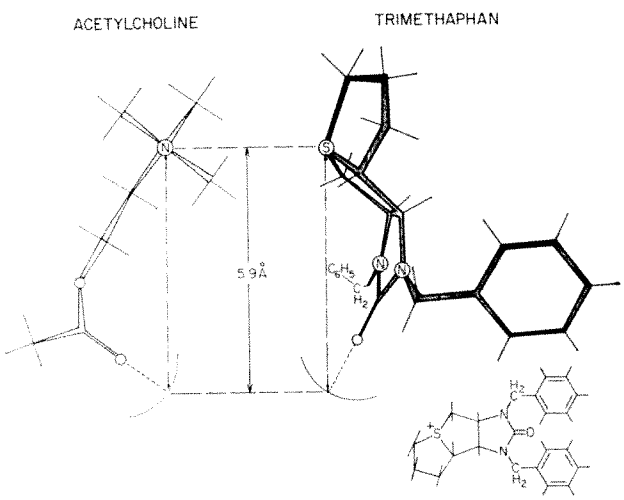

Fig. 6. In trimethaphan it is a sulphur atom which is charged. The distance from its centre to the centre of the van der Waals surface of the ureido oxygen is 5·9 Å.

both an anionic centre and an H-bond donor group the precise nature of which remains to be established. In Ach, the formation of an H-bond approximately 5·9 Å from the positive charge can be mediated only by the carbonyl oxygen; no conformation permits the ester oxygen to assume the position required for such an interaction. We therefore propose that the interaction of Ach with nicotinic receptors is stereospecifically determined by a coulombic interaction involving the quaternary nitrogen, and by the concurrent formation of an H-bond, for which the carbonyl oxygen acts as acceptor.

It is well known that organic cations, such as TMA (tetramethylammonium ion) and DMPP (dimethylphenylpiperazinium ion), which contain no potential H-bond acceptor, mimic the effects of acetylcholine. They do so especially well at synapses in autonomic ganglia. We shall consider the action of these substances later.

Muscarinic Agents

Pfeiffer[19] was the first to recognize the structural homologies among drugs active at parasympathetic sites. With the inadequate structural information then available, he formulated a proposal to account for the activity of these agents that was qualitatively confirmed in a subsequent analysis by Beckett[20], and ours is in accord with these.

The most potent muscarinic agonists and antagonists have a common set of structural elements which differs from, and does not overlap with, that found for the nicotinic series. In the muscarinic series the functional groups which determine interaction are (*a*) a quaternary ammonium grouping or its equivalent and (*b*) an unshared pair of electrons which can mediate the formation of an H-bond at approximately 4·4 Å from the centre of the positive charge. In addition, the interaction at muscarinic sites is strongly reinforced by a suitably located alkyl residue; the position of this residue can correspond to that of the methyl group in the acetyl moiety of Ach. These conclusions are derived from a consideration of four agonists and one set of antagonists.

F-2581 (Fig. 7) is the most potent muscarinic agent known[21]. The two oxygen atoms form part of the ring system and are symmetrically placed with respect to the positive charge, itself directly attached to the ring. These structural properties limit the separation of the positive charge and potential H-bond to the range of 4 to 5 Å.

Furmethide (Fig. 7) is another potent muscarinic agonist. In it the single oxygen atom is fixed in the unpuckered ring, minimizing conformational variations. The maximum distance which can be attained between the centre of the van der Waals surface of this oxygen and the charged quaternary nitrogen is about 4·4 Å. The addition of a methyl group to C-5 of furmethide increases the muscarinic potency by a factor of 10 (refs. 22 and 23). The position of this methyl group can easily be matched by the acetyl methyl group of Ach. This is one of numerous examples which show that a properly placed hydrophobic group enhances muscarinic activity and points to the involvement of the acetyl methyl group of Ach in muscarinic interactions.

The third compound which helps to establish the distance of about 4·4 Å is the classic muscarinic alkaloid, pilocarpine (Fig. 7). This contains two oxygen atoms which can act as H-bond acceptors, and two nitrogen atoms. Because of the restrictions imposed by the ring structure of pilocarpine, no combination of a single charged nitrogen and one H-bond acceptor site can be any closer than 4·3 Å. Because the maximum possible separation of the homologous groups in furmethide is 4·4 Å, we conclude that the muscarinic receptor interacts with Ach to form an H-bond between 4·3 and 4·4 Å from the cationic centre.

Meprochol (Fig. 7), another significant muscarinic agent contains only one oxygen, and it is analogous to the ester oxygen of acetylcholine. The muscarinic potency of meprochol is equal to that of acetylcholine[24]. Because meprochol has no potential H-bond acceptor which could assume the position of the carbonyl oxygen of acetylcholine, the latter cannot be essential for potent muscarinic activity.

It is also interesting that the more active remaining muscarinic drugs, such as muscarine, arecoline, 2-methyl-

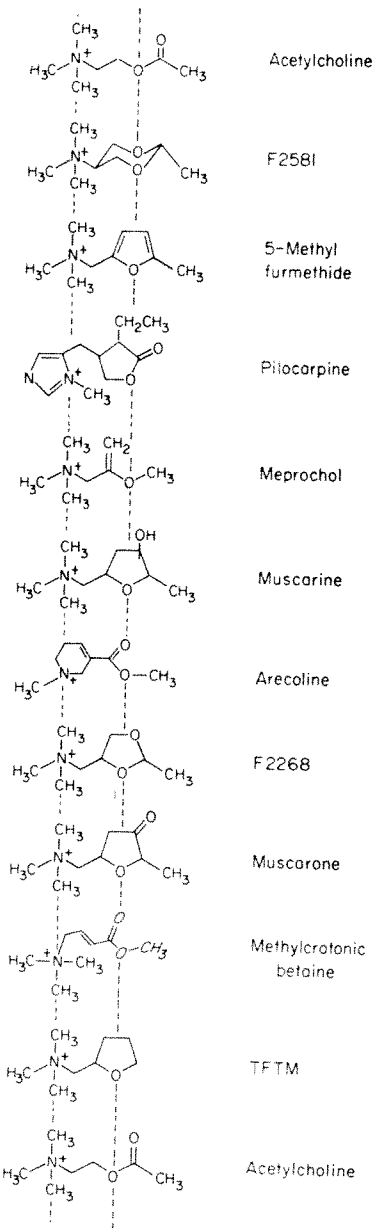

Fig. 7. All the drugs shown here contain an oxygen which, in terms o the distance between it and the charge centre, can attain a position equivalent to that of the ester oxygen in acetylcholine. Most of the more active drugs contain a methyl group which can assume a position equivalent to that of the acetyl-methyl group of acetylcholine.

4-dimethylaminomethyl-1-3-dioxolane (F2268) (ref. 25), muscarone, methylcrotonic betaine[26] and tetrahydrofuranyl-trimethylammonium ion (TFTM)[27] (Fig. 7) contain a potential H-bond acceptor 4·3 to 4·4 Å from the cationic centre. The most potent of these also have a methyl group in a position which can be assumed by the acetyl-methyl group of acetylcholine. Several of these compounds do not contain a potential hydrogen bonding function which is homologous with that of the carbonyl oxygen of acetylcholine: these are meprochol, methylfurmethide, TFTM and F2581.

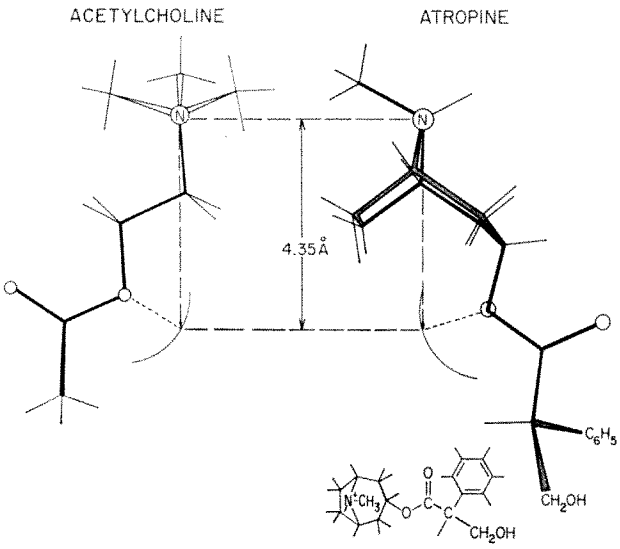

Fig. 8. Atropine, see text.

The potency of muscarine is markedly attenuated when any asymmetric centre is epimerized[28,29], and the same is true for acetyl-β-methylcholine[30,31]. The high degree of stereospecificity shown by the activity of these compounds is consistent with the view that optimal interaction with the muscarinic receptor normally involves three functional groups of the drug, in contrast to the two which seem to suffice at nicotinic junctions. This stereospecificity might also permit structural analysis which could identify the conformation of Ach that is responsible for its action at muscarinic sites[32]. But the sensitivity to epimerization which is reflected in the potency of the muscarine isomers contrasts with properties of several closely related compounds, that is, F2268, muscarone and 4,5-dehydromuscarine[20,25,26]. In some of the latter the muscarinic potency is much less strongly influenced by stereochemistry, and in others the pattern of activity of the various diastereoisomers does not coincide with that of the muscarines. These inconsistencies suggest that conclusions regarding the precise stereochemical requirements of the muscarinic receptor should be deferred. Beckett[20] has proposed one scheme for resolving this question. Additional insights may develop as further information about the properties of these molecules in solution becomes available.

In the muscarinic antagonist atropine (Fig. 8), the separation of the charged nitrogen and the H-bonding site on the ester oxygen is confined to a narrow range which includes the 4·4 Å distance observed in muscarinic agonists.

Deptropine (Fig. 9), like atropine, is a cholinergic antagonist at muscarinic sites. The oxygen which is the only potential H-bond acceptor in deptropine is stereochemically identical with the ester oxygen of atropine.

Like Ach itself, several drugs have both nicotinic and muscarinic actions. These include the γ-crotonyl betaines[26], muscarone, arecoline and pilocarpine. All of these, like Ach, contain distributions of functional groups which could mediate the formation of H-bonds at distances both 5·9 Å and 4·4 Å from the charge centre.

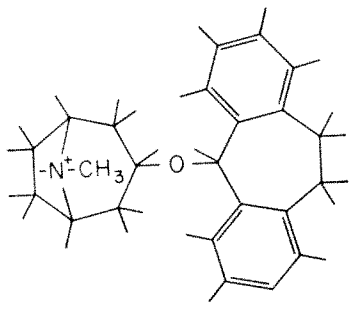

Fig. 9. Deptropine, see text.

As we have indicated, there are structural features common to agonists and antagonists within each family of cholinergic drugs. No precise expression or set of molecular properties seems to permit differentiation between agonists and antagonists. Increasing hydrophobicity and increasing structural rigidity are usually associated with antagonism. In the nicotinic series a tentative generalization can be formulated which relates to the alkyl substitution on the charge centre: molecules with more than two alkyl substituents larger than methyl are antagonists. One exception is the blocking action of hexamethonium in autonomic ganglia; another likely exception is the rigid alkaloid anagyrine, which is probably a nicotinic agonist. The most consistent structural property of muscarinic antagonists is the hydrophobic character which is conferred on them by large alkyl substituents on the charged nitrogen atom or by aromatic residues in the side chain, or both.

Functional Basis for Receptor Differentiation

The unsubstituted ammonium ion is inert at cholinergic junctions; cations which are active must have some hydrophobic character. The step-wise alkylation of ammonium (or other suitable cations) ultimately permits detectable interaction with the cholinergic receptor, the first expression of which is agonist action. The degree of alkylation which exists in trimethylammonium ion approaches the optimum required for this activity. The increased hydrophobicity that accompanies alkylation with larger substituents still permits interaction with the receptor, but the interaction is then expressed as antagonism.

The pharmacological activity of organic cations such as tetramethylammonium ion and DMPP indicates that the corresponding ammonium grouping in acetylcholine should be considered the true effector structure in the natural transmitter. That being so, if the response of all receptors were related to the charge alone, the activity

of TMA should be the same at all cholinergic sites. In fact, the relative potencies of TMA and Ach vary markedly at different cholinergic junctions; and, in view of the following considerations, these variations might provide some insight into the role of the individual functional groups in acetylcholine as they interact with the separate classes of receptors.

(1) TMA and Ach have equal potencies in autonomic ganglia[33], whereas the relative activity of TMA is lower by a factor of approximately 100 in skeletal muscle[34,35] and by a factor of 1,000 at the muscarinic junctions in smooth muscle[34].

(2) The synaptic delay and rise time of endplate potentials and excitatory post-synaptic potentials at nicotinic sites are much shorter than those of the junctional potentials at the muscarinic synapses in smooth muscle[36,37].

(3) In the rabbit superior cervical ganglion, where a complex series of responses follow preganglionic stimulation, the early, fast response is blocked by the nicotinic blocking agents tubocurarine and dihydrobetaerythroidine. The late, slower and ten-fold longer lasting response is blocked by atropine and is thus muscarinic[2]. Likewise, the slow prolonged responses to iontophoretically applied Ach, of neurones in the central nervous system are, predominantly muscarinic[38,39]. These findings imply that nicotinic junctions are more sensitive and responsive to chemical stimulation than muscarinic junctions.

This functional group analysis and the relative potencies of TMA and Ach suggest the following correlation with the physiological observations. In autonomic ganglia the demands on the transmitter are minimal; a transient interaction with simple, appropriate hydrophobic cations such as TMA is sufficient to depolarize the post-synaptic fibre. At neuromuscular junctions the demands on the receptor–transmitter complex are more exacting: the addition of an H-bond to the coulombic interaction can meet these demands by mediating a more precise and prolonged positioning of the quaternary ammonium group with the complementary receptor structure. At the sluggish muscarinic sites the demands are greatest of all, and the simple cation TMA is much less potent than Ach. At muscarinic junctions a transmitter–receptor interaction based on electrostatic elements alone is not adequate to produce a response efficiently with low concentrations of drug. Superimposition of hydrogen bonding and hydrophobic interactions at these sites should increase the lifetime of the complex and thereby enable the cationic portion of Ach to excite the tissue efficiently. As has been suggested previously, prolonged interaction of the drug and receptor would help to explain the long duration of "slow potentials" and the marked facilitation which is evident in the rabbit colon–pelvic nerve preparation[36].

The view of Ach which emerges from these considerations is that of a moderately hydrophobic cation, with functional versatility which is increased by several accessory structural elements; these are the two oxygen atoms, which can act as H-bond acceptors, and the methyl group which can participate in hydrophobic interactions. The single molecule, Ach, influences the activity of many target tissues whose ultimate response to the neutral transmitter is expressed in many different forms (for example, secretion, muscle contraction and bradycardia). It is likely that there are significant differences in the physical–chemical parameters, and particularly in the time constants of the numerous processes which culminate in the response of the various target tissues to Ach. The limiting factors in the different tissue responses would impose different requirements on the excitatory mechanism in each case. These needs could be met by modifications of the binding site on the receptor which would produce concomitant changes in the receptor–transmitter complex: the latter might include alterations in functional group specificity, in affinity, and in the rate of association and dissociation. We visualize that all Ach receptors interact with, and respond to, the charged quaternary ammonium moiety; the nicotinic receptor, at least at the neuromuscular junction, exploits in addition one accessory grouping—the carbonyl oxygen; the muscarinic receptor interacts with two of the accessory structures of Ach, the ester oxygen and the methyl group. Still other receptor specificities may remain to be characterized, especially in the central nervous system. Such a multiplicity of receptor specificities, which is apparent also in adrenergic transmission, is a reasonable basis for functional and pharmacological diversity in excitable tissues; it would provide a mechanism for qualitative and quantitative modulation of cellular responses to excitation.

We thank Dr Henry Sobell for providing details of the crystal structure of *d*-tubocurarine before publication, and Dr A. S. V. Burgen for helpful and stimulating discussions and for reading the manuscript.

Organic molecules found in meteorites seem to have been formed before the meteorites reached Earth.

THE Oparin–Haldane[1,2] hypothesis of chemical evolution, postulating the formation of organic compounds before the appearance of life on Earth, has been substantiated by experiments in the laboratory[3–5]. Many of the molecules important to living processes can be synthesized in conditions which may have prevailed on a primitive planet[6,7]. The fundamental concept of chemical evolution would be further substantiated by the finding of compounds of biological significance in extraterrestrial conditions.

Recent studies of intergalactic space, using the techniques of radioastronomy, have shown the presence of water[8,9], ammonia[10], hydrogen cyanide[11], formaldehyde[12], carbon monoxide[13] and cyanoacetylene[14], which are considered to be precursors in the formation of many biochemicals. Some evidence has also been put forward for the possible presence of molecules such as porphyrins[15] and polyaromatic compounds[16,17] in the interstellar medium. The lunar samples from the Apollo 11 and Apollo 12 missions provided a further opportunity for the search for carbon compounds in extraterrestrial materials, but the analysis of the fines from Mare Tranquillitatis[18] and Oceanus Procellarum[19] revealed only minute traces of such compounds. No conclusive evidence is available for the presence of any biomolecules indigenous to the lunar surface.

On the other hand, meteorites have been analysed for organic compounds for over a century[20–22]. Berzelius[23] examined the Alais, Wöhler[24] the Kaba and Berthelot[25] the Orgueil, and reported the presence of substances of organic origin. These investigations have continued, and there is general agreement about the presence of polymeric organic matter in carbonaceous chondrites[20]. The inherent potentiality for contamination resulting from the ubiquitous distribution of biomolecules on Earth[26,27] leads us to believe that many of the results reporting the presence of organic compounds in meteorites are inconclusive, but the results of our present investigation seem to resolve some of these ambiguities and provide evidence for amino-acids and hydrocarbons of possible extraterrestrial origin.

The Murchison meteorite fell at about 11.00 a.m., local time, September 28, 1969, near Murchison, Victoria, Australia (lat. 36° 36′, long. 145° 12′)[28]. The parent object broke up during flight and scattered many fragments over an area of about 5 square miles. Most fractured surfaces on the individual pieces have fusion crusts. Notable and distinctive features of many of the individual stones are networks of deep cracks extending into their interiors. Several stones were picked up soon after the fall and many have been collected since that time particularly during February and March, 1970. Many of the stones broke on impact with the ground.

For this study we selected those stones which had the fewest cracks, the least exterior contamination, and which generally appeared to have a massive character. The samples we examined contained 2·0 weight per cent carbon and 0·16 weight per cent nitrogen. Chemically, the Murchison meteorite is a type II carbonaceous chondrite (C-2).

Amino-acids

An interior piece of the meteorite (10 g) was pulverized and refluxed with 50 ml. of triply distilled water for 20 h at about 110° C. The extract was recovered by centrifugation and the residue rinsed twice with 50 ml. of water. The extract and rinses were combined, evaporated to dryness, and hydrolysed with 50 ml. of 6 M HCl for 20 h at about 100° C. This hydrolysate was evaporated to dryness and desalted by ion exchange using Dowex 50 (H^+) followed by Dowex 2 (OH^-). Portions of the recovered product were analysed by conventional ion exchange chromatography (Beckman–Spinco 120), by capillary gas chromatography of amino-acid derivatives (Perkin Elmer 881), and by gas chromatography combined with mass spectrometry (CEC 21-491). The meteorite residue after water extraction was hydrolysed with 6 M HCl for 20 h at about 110° C. This hydrolysate was treated in the same manner as the water extract.

Conventional ion exchange chromatography of the hydrolysed water extract from the 10 g sample revealed a number of peaks having retention times similar to common amino-acids. Five abundant amino-acids suggested by the chromatograms were glycine (6 μg/g), alanine (3 μg/g), glutamic acid (3 μg/g), valine (2 μg/g) and proline (1 μg/g).

The presence of the amino-acids, suggested by ion exchange chromatography, and their enantiomeric distribution were established by gas chromatography of the N-trifluoroacetyl-D-2-butyl esters of the amino-acids[29–32]. In this procedure, amino-acids with an asymmetric centre were transformed to diastereomers and the enantiomeric distribution of these compounds was determined on two different capillary columns—'UCON 75-H-90,000' and 'XE 60'. Fig. 1 shows a representative chromatogram resulting from an analysis of amino-acid derivatives. Peaks of the common amino-acids identified on the chromatogram confirm the identification made by ion exchange chromatography. Moreover, both enantiomers of amino-acids with asymmetric centres are present. The percentage of D-amino-acid enantiomers present was calculated from the gas chromatograms to be about 50 per cent for alanine, 45 per cent for glutamic acid, 40–47 per cent for valine and 40–43 per cent for proline. The presence of 2-methylalanine and sarcosine, amino-

acids not commonly found in biological systems, was suggested by the gas chromatogram.

To obtain an unambiguous identification, the compounds eluted from the gas chromatograph were introduced through a membrane separator into the mass spectrometer. The mass spectra obtained were compared with the spectra of known standards. In this manner the identities of the amino-acids, glycine, alanine, valine, proline and glutamic acid, were confirmed. Furthermore, the identity of each enantiomeric derivative of alanine, valine and proline was established. The D enantiomeric derivative of glutamic acid was confirmed but because of interfering compounds the spectra of the L enantiomeric derivative was equivocal.

The identities of 2-methylalanine and sarcosine were also established by mass spectrometry. Fig. 2 shows the spectra obtained from a standard N-TFA–D2-butyl ester of 2-methylalanine compared with the derivatized compound from the Murchison meteorite sample. Similarly, Fig. 3 illustrates the spectra of a derivatized standard sample of sarcosine and a derivatized compound from the meteorite sample. As in the mass spectra of the N-TFA-*n*-butyl esters of amino-acids[33] the key peaks in the spectra of the N-TFA-D-2-butyl esters of 2-methylalanine and sarcosine are the $(M-C_4H_9COO)^+$ peak and the $(M-C_4H_9O)^+$ peak.

Amino-acids have been found previously in other meteorites[20,34] but because the distributional patterns of these amino-acids are similar to amino-acids in fingerprints, the occurrence of amino-acids in meteorites has commonly been attributed to contamination[20]. The total concentration of glycine, alanine, valine, proline and glutamic acid obtained from Murchison meteorite was about 15 μg/g, which is about twice the total concentration of these same compounds found free in Murray, another type II carbonaceous chondrite[34]. In previous work serine has usually been reported as among the most abundant amino-acid in both meteorites and fingerprints[20]. In this study serine was tentatively identified only by ion exchange chromatography and its concentration was an order of magnitude less than the concentration of glycine. The unique distribution of amino-acids in the Murchison meteorite cannot be explained satisfactorily on the basis of contamination by human hands.

The distribution of the enantiomers of alanine, valine, proline and glutamic acid also supports the idea that the amino-acids from the Murchison meteorite are not recent biological contaminants. Amino-acids in living systems are of the L configuration except in rare instances. In recent sediments the L configuration dominates[32].

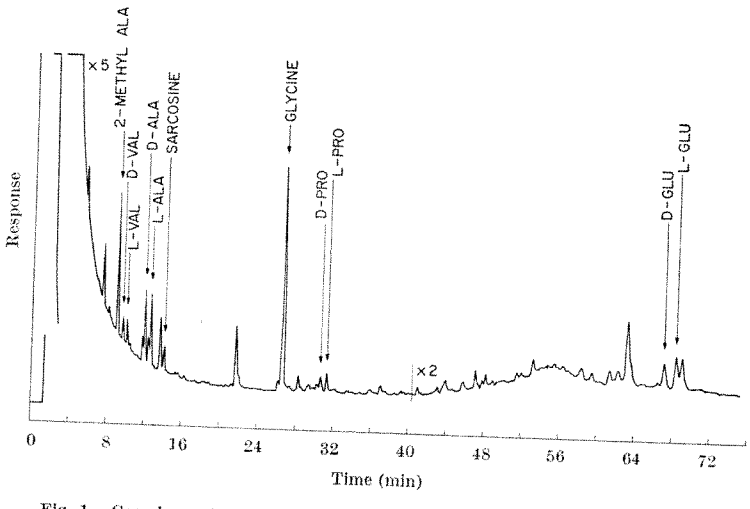

Fig. 1. Gas chromatogram of N-trifluoroacetyl-D-2-butyl esters of amino-acids in acid hydrolysed water extract of a 10 g sample of the Murchison meteorite. Gas chromatography: 0·02 inch × 150 feet capillary column coated with 'UCON 75-H-90,000'; temperature programmed from 100° to 150° C at 1° C/min.

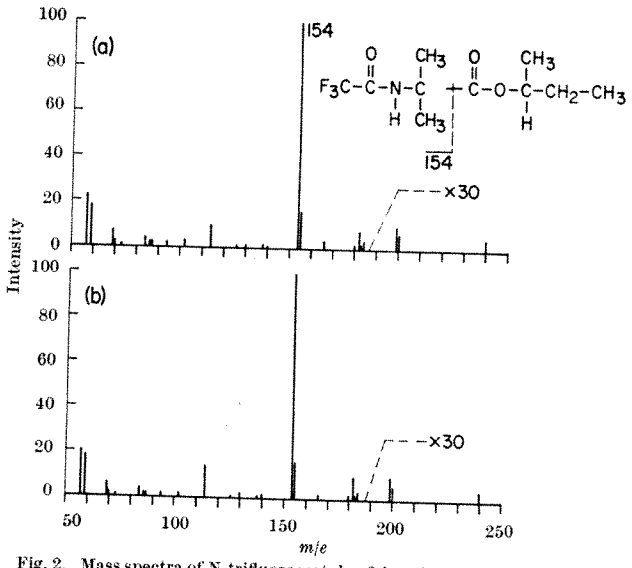

Fig. 2. Mass spectra of N-trifluoroacetyl-D-2-butyl ester of: *a*, 2-methylalanine standard; *b*, compound from the Murchison meteorite.

Studies of amino-acid configurations in other carbonaceous chondrites show that the distribution of enantiomers resembles those of recent sediments and soils[35]. The D and L enantiomers of amino-acids in the Murchison meteorite are almost equally abundant. Slight biological contamination might account for the small dominance of the L isomers of valine, proline and glutamic acid. The distribution of amino-acid enantiomers in Murchison can be accounted for either as a racemic modification of biologically produced amino-acids or as a racemic mixture of abiotically produced amino-acids. The discovery of 2-methylalanine and sarcosine, which are not commonly found in proteins, supports the hypothesis that the whole collection of amino-acids was produced abiotically. In chemical evolution experiments simulating the primitive atmosphere, both sarcosine and 2-methylalanine have been noted among the products[36].

Hydrocarbons

Ten g of the pulverized meteorite were extracted by sonication in a centrifuge tube three times successively, with about 20 ml. benzene–methanol (9 : 1). After centrifugation the extract was evaporated to dryness in a rotary evaporator. This residue was redissolved in 1–2 ml. hexane, which was applied to a 10 g activated silica gel column. The column was eluted with 15 ml. portions of hexane, benzene and benzene–methanol. Activated copper strips were placed in the hexane and benzene fractions and allowed to stand overnight to remove any free sulphur. After the removal of the copper the three fractions were evaporated to about 100 μl. About one-tenth of the hexane fraction was analysed by gas chromatography using a 50 foot 'OV-1' support coated open tubular column in a Perkin–Elmer '880' gas chromatograph. The remainder of the sample was analysed by gas chromatography combined mass spectrometry ('CEC 21-491'). Mass spectra were taken every 3 min during the chromatography.

A second sample (15 g) was similarly extracted. After the removal of sulphur the hexane fraction was analysed by thin layer chromatography using silica gel plates impregnated with silver nitrate to separate saturated alkanes from the unsaturated[37]. Saturated alkanes were eluted from the silica gel with hexane, and one-twenty-

fifth of the eluate was analysed by gas chromatography as before. A small fraction (approximately one-third) was volatilized directly into the source of a 'CEC 21-110' mass spectrometer for a series of high resolution photoplate spectra, and one-third was vaporized directly into the source of the 'CEC 21-110' mass spectrometer to obtain a series of low resolution spectra.

The chromatograms in Fig. 4 indicate that a very complex mixture of alkanes has been isolated from the two meteorite samples. A rough estimate of their abundance can be made by assuming that the arch shaped trace is an equilateral triangle composed of a series of peaks spaced at very close intervals. This estimate suggests that about 350 μg of alkanes were isolated from the 10 g sample and 175 μg from the 15 g sample.

Contamination seems to be limited to a small group of compounds eluted at 210°–249° C. These have been routinely observed in our laboratory and seem to be airborne contaminants.

The distribution pattern of the alkanes isolated from the 10 g sample is a symmetrical trace (Fig. 4) with a peak at 180° C, which corresponds to the elution temperature of n-C_{18}, with a shoulder in the 100°–140° C region. On this shoulder (130° C) is a peak with the retention time corresponding to a saturated n-C_{13} hydrocarbon, and represents about 0·1 μg of hydrocarbons. Other—much smaller—peaks on the chromatogram correspond, in retention time, to n-C_{18} and n-C_{22}–C_{23}. The mass spectra of the various GLC fractions taken at 3 min intervals were very similar and showed a predominance of fragment ions corresponding to the homologous series:

$$(C_nH_{2n-3})^+ > (C_nH_{2n-1})^+ > (C_nH_{2n-5})^+ > (C_nH_{2n+1})^+$$

Mass spectra of fractions eluting from the column at higher temperatures show an increasing predominance of the $(C_nH_{2n}-5)^+$ ion over the $(C_nH_{2n}-1)^+$ ion. The peak emerging at 130° C has not been completely characterized. The mass spectra of the species coinciding with the appearance of this peak on the gas chromatogram shows intense ions at m/e 127 and 182.

The gas chromatographic distribution pattern of the saturated alkanes isolated from the 15 g sample by thin layer chromatography is also a symmetrical trace (Fig. 4), but it differs from the first sample, in that it reaches a maximum at 160° C ($n-C_{16}$ retention time) and does not have a shoulder in the 100°–140° C region. This may result from removal of small amounts of unsaturated isomers by $AgNO_3$ chromatography. The low resolution mass spectra of this alkane mixture resembled those from the first sample. Several predominant molecular ions are present (Fig. 5), suggesting that the hydrocarbons in this particular sample are relatively stable to fragmentation on electron bombardment. These molecular ions (m/e 278, 292, 306) correspond to the bicyclic, homologous series C_nH_{2n-4}. A series of relatively intense peaks at m/e 221, 235 and 263 suggests that the loss of hydrocarbon fragments, ranging from $-CH_3$ to $-C_4H_9$, is a favourable process. This evidence, and the relatively large intensity of the m/e 151 peak relative to m/e 137 and m/e 165, suggests that these hydrocarbons closely

Gas chromatograms of alkanes isolated from benzene–methanol extracts of two samples of the Murchison meteorite: a, 1/10 of alkane fraction isolated from 10 g sample (attenuation ×50); b, 1/25 of alkane fraction isolated from 15 g sample (attenuation ×20); c, chromatographic blank (attenuation ×20) gas chromatography: 50 feet support coated open tubular column with 'OV-1' liquid phase; temperature programmed from 100° to 240° C at 2° C/min.

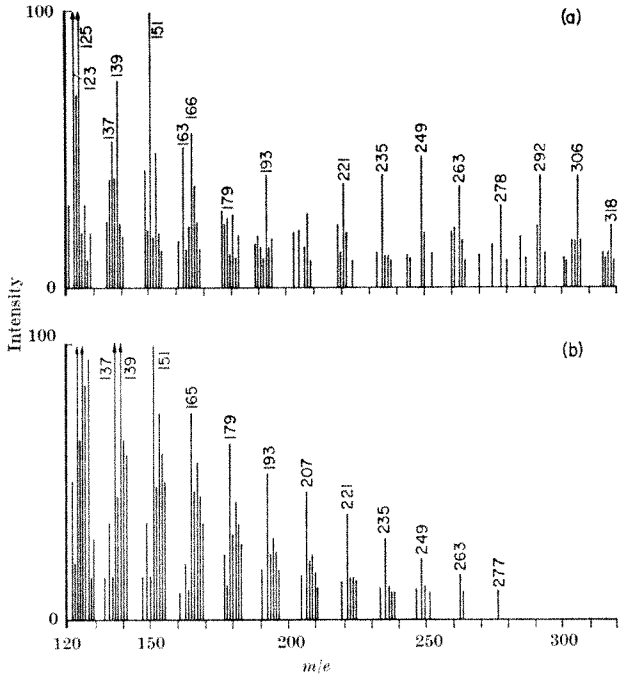

Fig. 5. Low resolution mass spectrum of alkane fractions obtained on volatilization at 125° C from the direct probe of a 'CEC 21–110' mass spectrometer. Ion intensities normalized to *m/e* 151. *a*, Fraction from 15 g sample of the Murchison meteorite; *b*, fraction from spark discharge in methane.

recemble decahydronaphthalenes containing short chain hydrocarbon substituents.

There is a marked resemblance between the gas chromatographic traces of the aliphatic hydrocarbons synthesized by the action of electrical discharges on methane[38] and those from the meteorite. The analysis of these samples by thin layer chromatography on silica gel plates impregnated with $AgNO_3$ (ref. 37) indicates that they consist largely of saturated alkanes. The mass spectral data reveal the same dominant homologous series in both samples (Fig. 5). The similarity between the aliphatic hydrocarbons from the meteorite and the spark discharge material, on these three counts, is suggestive of a possible abiogenic origin for the hydrocarbons in the Murchison meteorite.

Further investigations are in progress to determine the possible presence of aromatic and unsaturated hydrocarbons, carboxylic acids and porphyrins.

Carbon Isotope Distribution

Various carbon compounds were analysed for $^{13}C/^{12}C$ following the technique of Smith and Kaplan[39]. The results (expressed in the conventional manner as $\delta^{13}C$, relative to Peedee Belemnite) are given in Table 1. These results, together with the carbon content (2·5 per cent), place the meteorite as a type II carbonaceous chondrite[39]. The values obtained for the organic solvent extractable material are significantly more enriched in ^{13}C than any previous measurements on such compounds in other carbonaceous chondrites. Extracts of terrestrial sediments and petroleum fall in the range $\delta^{13}C = -25$ to -35 parts per thousand[40,41]. Results obtained from the meteorite confirm the indigenous nature of the carbon and indicate that the amount of terrestrial contamination is insignificantly low.

Table 1

Form of carbon analysed	$\sigma^{13}C$ PDB (parts per thousand)
(i) Total carbon	−7·3, −7·1
(ii) Carbonate	+45·4
(iii) Benzene–methanol soluble compounds	+4·4, +4·8, +5·9
(iv) Insoluble carbon (after solvent extraction and demineralization of silicates with HF)	

The results of our investigation suggest the indigenous nature of amino-acids and hydrocarbons in the Murchison meteorite. The $\delta^{13}C$ values of +4·43 to +5·93 for the extractable organic material of the meteorite fall into a range widely different from terrestrial organic matter, and the presence of the amino-acids glycine, alanine, valine, proline, glutamic acid, 2-methylalanine and sarcosine was unequivocally established. The presence of almost equal amounts of the D and L enantiomers of valine, proline, alanine and glutamic acid minimizes the possibility of terrestrial contamination and suggests a possible extraterrestrial origin. The presence of the two amino-acids, 2-methylalanine and sarcosine, which are not generally found in biological systems, is indicative of a possible abiogenic synthesis. The gas chromatographic pattern of distribution of hydrocarbons and their mass spectrometry fragmentation pattern similar to that obtained by an abiotic synthesis in the laboratory support the contention that the organic molecules identified here are abiotic and possibly extraterrestrial in origin.

We thank Mr Michael Romiez and Miss Cheryl Boynton of the Ames Research Center and Mrs Chari Petrowski of the Department of Geology, University of California, Los Angeles, for their assistance.

An RNA dependent DNA polymerase analogous to that of RNA tumour viruses has been found in lymphoblasts of leukaemic patients but not of normal donors. The enzyme can use an RNA template from mammalian cells to synthesize DNA.

RECENT reports by Temin[1] and Baltimore[2] that an RNA dependent DNA polymerase activity is present in oncogenic RNA viruses, now confirmed and extended in other laboratories[3-5], provide a mechanism by which an RNA virus may insert stable genetic information into a host cell genome.

The aetiology of human acute leukaemia is not known, but a role for RNA oncogenic viruses in human neoplasia has been proposed for several reasons[6]. Although RNA virus particles have not been clearly associated with human leukaemia, we have examined human leukaemic cells for the presence of an RNA dependent DNA polymerase because: (1) it is possible that RNA virus particles are regularly present in human leukaemic cells but cannot be detected by ordinary means. The presence of a unique enzyme might be a more sensitive index. (2) The virus particles may never be formed but the viral genome would be integrated and undetected, yet functional in the host cell. The enzyme could be required for subsequent formation of additional viral DNA used in infection of other host cells. (3) Information flow from RNA to DNA raises interesting questions regarding gene amplification during biochemical cytodifferentiation. This mechanism could have considerable implications for cell growth and differentiation[7], and because human leukaemia has been considered a disorder of cell differentiation, it may also have implications for leukaemogenesis[8,9].

Choice and Preparation of Cells

Several considerations influenced our choice of cells. First, acute leukaemia was selected rather than the chronic form because the characteristics of the former cell type are more malignant and less often contaminated with other types of leucocytes. In leukaemia of an acute "blastic" type, a population of almost 100 per cent blasts can be obtained directly from a patient. Second, the lymphoblastic type was chosen rather than the myeloblastic (granulocytic type) because the latter are more likely to be associated with other more differentiated cells of the myeloid (granulocytic) series. These cells contain abundant lysosomes with high nuclease activities, making any RNA analysis or polymerase assay extremely difficult[9]. Third, proliferative lymphoblasts can also be obtained from normal human volunteers. This is achieved by transformation of normal peripheral blood lymphocytes to lymphoblasts with a mitogenic agent. Fourth, the polymerase activities of tumour cells are generally higher than those of normal adult organs. A much greater content of various polymerases would be more likely to lead to a spurious interpretation of a unique polymerase in such cell types. For this reason, we would expect a better controlled comparison between normal and neoplastic cells of comparable DNA and RNA polymerase activities.

The simple use of peripheral blood leucocytes, which consist primarily of fully mature non-proliferating granulocytes and lymphocytes, cannot be considered as controls for leukaemic blast cells, particularly in view of the fact that these cells have minimal or no detectable DNA dependent DNA polymerase activity[9]. On the other hand, after 72 h of stimulation of normal human lymphocytes with phytohaemagglutinin (PHA), DNA synthesis is maximal[10]. In addition, Loeb *et al.*[11] have reported a 30 to 100-fold induction of DNA polymerase at this time, so that activities reach levels comparable with neoplastic cells, and Hausen *et al.*[12] have reported an induction of RNA polymerase in lymphocytes stimulated with PHA. We have confirmed both these findings (unpublished results). Fifth, human cells obtained directly from peripheral blood instead of human tissue culture cell lines were chosen for these initial investigations because they obviously are a more true reflexion of the disease. Furthermore, there is much less chance of contamination with microorganisms or of developing mutations not relevant to leukaemogenesis.

The leukaemic cells utilized in this study, therefore, were peripheral blood lymphoblasts obtained from three patients with acute lymphoblastic leukaemia (ALL). In each, the number of lymphoblasts was more than 100,000/mm^3 of blood. Two patients were untreated and the third received hydroxyurea for one day. Normal lymphocytes were obtained from the peripheral blood lymphocytes of forty-eight normal donors.

The lymphocytes were separated from other blood cells, as previously described[13], except that an additional nylon column chromatographic step was carried out to obtain more pure cell populations (more than 98 per cent lymphocytes). These cells were incubated with the mitogenic agent and harvested after 72 h, as previously described[13]. In our conditions, at 72 h the number of cells transformed to lymphoblasts and the rate of DNA synthesis are maximum[10]. After terminating the incubation, the cells were extensively washed with 0·15 NaCl and used for polymerase assays.

RNA dependent DNA Polymerase Activity

Nucleic acid "free" preparations were made by gentle manual homogenization (Ten-Broeck) of purified lymphoblast pellets in 3 volumes of 25 mM Tris-sulphate buffer, *p*H 8·3; 1 mM $MgSO_4$; 6 mM NaCl; 4 mM dithiothreitol; and 0·1 mM EDTA. The samples were centrifuged at 15,000 r.p.m., and the supernatants and pellets separated. The pellets of membranes and nuclei were washed with the same buffer with gentle homogenization. After centrifugation the wash (second supernatants) was combined with the first supernatants and the nuclei–membrane pellets removed.

Nucleic acids were removed from the supernatant fractions by successive precipitations with $MnCl_2$ and

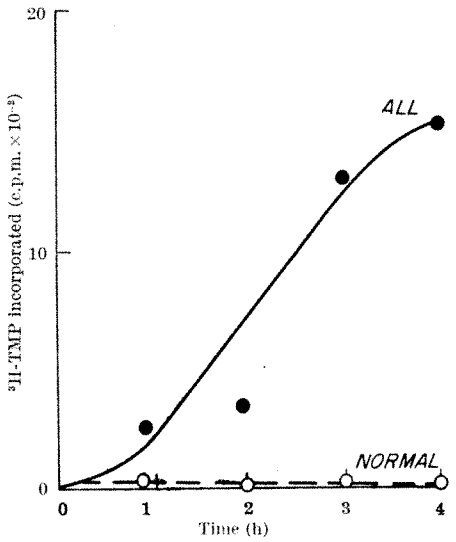

Fig. 1. Kinetics of ^{3}H-TMP incorporation into TCA precipitable materials. Reaction mixtures in a final volume of 1 ml. contained: 0·295 mg protein from the nucleic acid "free" crude extract (see text); 50 μmoles Tris-HCl buffer, *p*H 8·3; 6·0 μmoles MgAc; 20 μmoles of dithiothreitol; 60 μmoles of NaCl; 0·8 μmole each of dATP, dCTP, and dGTP; 10 μCi [^{3}H-methyl]-TTP (New England Nuclear, 7·7 mCi/μmole); and 40 μg of rat liver RNA. (Later experiments revealed that concentrations of RNA lower than 10 μg/ml. were more effective for template activity.) Samples were incubated at 37° C and were withdrawn at intervals and the reactions terminated by the addition of 0·5 ml. of cold 0·08 M Na-pyrophosphate with 200 μg of yeast nucleic acid added as a carrier prior to precipitation of macromolecules by adjustment to 12 per cent TCA. The precipitates were then washed extensively with cold 5 per cent TCA on Millipore filters, dried, and dissolved in 2·0 ml. of Beckman Bio-solv No. 3. 10 ml. of 'Omnifluor'-toluene were added, and the samples were counted in a liquid scintillation counter. ●—●, Activity of RNA dependent DNA polymerase from ALL lymphoblasts; ○ - - - ○, activity of lymphoblasts from PHA stimulated lymphocytes of normal donors. Counts were corrected for endogenous templating activity at each point. Heated controls (85° C for 5 min) incubated for the same period showed no significant non-specific trapping of radioactivity. The rat liver RNA was prepared by repeated phenol extraction and ethanol precipitation of the supernatant obtained after homogenization of liver slices (General Biochemical Co.). The commercial preparation was treated with deoxyribonuclease and the enzyme removed by phenol extraction and DEAE cellulose chromatography. The fractions of RNA eluting at 0·7 M NaCl were combined and after precipitation with ethanol this RNA was used as the template.

protamine sulphate. The final supernatants were the nucleic acid "free" preparations. Subsequent purifications were performed by elution of these fractions from DEAE-cellulose and gel filtration columns. The final fraction, designated the gel filtration preparation, was purified between 200 and 270-fold. More detailed information on the method of purification will be described elsewhere.

No RNA dependent DNA polymerase activity was detected in any of the preparations of normal lymphoblasts obtained from a total of 48 normal donors. Fig. 1 shows a comparison of the kinetics of incorporation of ^{3}H-TMP by nucleic acid "free" preparations from human ALL lymphoblasts (Patient 1), and one of the normal lymphoblasts in a DNA polymerase assay dependent on a rat liver RNA. The activity in the ALL lymphoblasts cannot be maximum because later experiments with other preparations revealed that RNA and TTP concentrations were not optimum. But with optimum conditions, activity could again not be demonstrated in the normal lymphoblasts.

A small endogenous reaction with both the leukaemic and normal lymphoblasts was observed with these nucleic acid "free" preparations, apparently due to contamination with DNA dependent DNA polymerase and a small amount of DNA in this relatively crude extract. A lag in kinetics was observed during the first hour of incubation similar to the reaction described by Baltimore with Rauscher mouse leukaemia virus RNA dependent DNA polymerase[2]. This might be due to interference in the process of template binding to enzyme.

Fig. 2 shows the kinetics of incorporation of ^{3}H-TMP in the presence of rat liver RNA by a more purified enzyme (G-100 gel filtration following initial steps described above) from human ALL lymphoblasts (Patient 2). This preparation is free of DNA as judged by diphenylamine assay, and unlike the less purified preparation there is no polymerase activity in the absence of an RNA template. An additional difference is the absence of lag in the initial period of incubation. This was also noted in another human acute leukaemic G-100 gel filtration preparation (Patient 3). The RNA dependent DNA polymerase activity of Patient 3 (c.p.m./μg protein/h) was approximately the same as Patient 2. Also shown in Fig. 2 are the results obtained when the "template" was pre-incubated for 1 h with ribonuclease (11 μg/ml.). Ribonuclease treatment completely removed the "template" activity of the RNA preparation. In other experiments with a human tumour cell line, 90 per cent inhibition of RNA template activity was obtained with as little as 0·2 μg/ml. of ribonuclease (observation of R. G. Smith and F. Herrera in our laboratory).

As described above and shown in Table 1, the reaction depends completely on the addition of rat liver RNA. The reaction required Mg^{2+} and deoxynucleoside triphosphates.

The Template is RNA

We have excluded the possibility that rat liver RNA might have been contaminated with a trace amount of DNA despite the initial treatment with deoxyribonuclease (see legend to Fig. 1 for purification of the RNA). The rat liver RNA was pre-incubated with deoxyribonuclease followed by subsequent removal of the enzyme as described in Table 2. Extensive treatment with deoxyribonuclease again showed no effect on the template activity of the purified RNA. But after pre-incubation with ribonuclease all activity was lost (Fig. 2). The reason for this might be that ribonuclease, a basic protein, could inhibit the polymerase reaction by interfering with the enzyme-template complex formation. Similar to the approach used by Baltimore[2], the effect of lysozyme, another basic protein, was also examined. No effect of lysozyme was found on the ALL enzyme with rat liver RNA as template even with a 10-fold increase in concentration (Table 3).

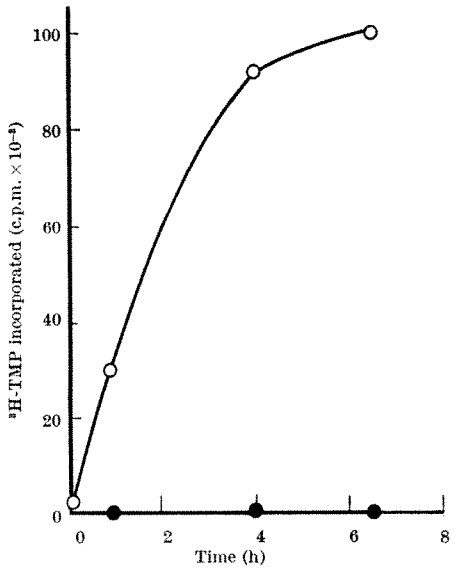

Fig. 2. The effect of ribonuclease hydrolysis on rat liver RNA template activity with the G-100 gel filtration partially purified RNA dependent DNA polymerase from ALL lymphoblasts. Rat liver RNA (20 μg) was incubated with 11 μg of highly purified pancreatic ribonuclease (crystalline, Worthington) at 37° C for 60 min in 1 ml. of 10 mM Tris-HCl, buffer *p*H 7·3, with 5 mM sodium acetate, prior to assay for its template activity. The assay system was the same as described in Fig. 1 except that 25 μCi/ml. of ^{3}H-TTP was used. ○, Kinetics of RNA dependent DNA polymerase with the untreated rat liver RNA template; ●, activity with the ribonuclease digested rat liver RNA as template.

Further evidence that the template is RNA rather than a DNA contaminant was obtained by assay for DNA. Two mg of the rat liver RNA was precipitated with perchloric acid and assayed for reactivity with diphenylamine. No deoxyribose was detected (Table 2).

We estimated the size of the rat liver RNA template by gel filtration (G-100) and sucrose gradient (5 to 25 per cent) centrifugation for 16 h at 105,000*g*. The results showed that approximately 85 per cent of the active template moved coincident with 4S RNA, while the remaining 15 per cent was RNA with a molecular weight greater than 150,000 (Table 2).

It is possible that an RNA dependent DNA polymerase is present in mammalian cells to amplify RNA species and does not have specificity for viral RNA. For most of these experiments, therefore, mammalian RNA was chosen as template. But, to verify further that the enzyme responds to RNA, the synthetic ribopolynucleotide poly rA·poly rU (10 μg/ml.) was tested, and it showed activity comparable with the results shown in Fig. 2 with rat liver RNA (see Table 1).

That the product is DNA is suggested by the incorporation of deoxynucleoside triphosphates into an acid precipitable form. The nature of the product was further investigated by determining the effects of various hydrolytic agents. Table 3 shows (1) that the reaction product is completely hydrolysed by deoxyribonuclease, (2) but it is not hydrolysed by ribonuclease or trypsin, and (3) it is alkaline resistant. Experiments are in progress to characterize it further.

Table 1. NATURE OF RNA DEPENDENT DNA POLYMERASE REACTION

Reaction mixture	c.p.m./ml. minus background
Complete, with rat liver RNA 40 μg/ml.	4,149
Complete, with rat liver RNA 10 μg/ml.	5,806
Complete, with poly rA · poly rU 10 μg/ml.	9,760
Without RNA template	0
Without $MgCl_2$	0
Without dCTP	405
Without dATP	622

The assay system was similar to that described in the legend to Fig. 1, except that 22·5 μg of the G-100 gel filtration partially purified enzyme was used. Incubations were carried out at 37° C for 2 h. Endogenous incorporation (no RNA template) was taken as the background and consistently gave values close to 200 c.p.m. Recent experiments have shown that maximum activity is obtained with concentrations of template less than 10 μg/ml.

Table 2. PROPERTIES OF THE MAMMALIAN RNA TEMPLATE

Determinations	Comments
Ribonuclease sensitivity 11 μg/ml.	100 per cent
Lysozyme sensitivity 100 μg/ml.	None
Deoxyribonuclease sensitivity 200 μg/ml.	None
Diphenylamine assay of deoxyribonuclease treated RNA template	No deoxyribose
Sucrose (5 to 25 per cent) equilibrium centrifugation	Major fraction has coincidence with 4S marker. Also small amount of high molecular weight component
DEAE-cellulose chromatography	Coincidence with 4S marker
Amino acid (^{14}C-aspartic acid or ^{14}C-serine) acceptance	0·4 pmoles per μg RNA

Assay systems were identical to those described in the previous table except ^{3}H-TTP was increased to 40 μCi/ml. RNA template concentration was 50 μg/ml. Controls (no treatment) gave 5,480 c.p.m. The increase in counts compared to previous experiments is attributed to the increase in ^{3}H-TTP. The ribonuclease sensitivity was determined by pre-incubation of the template RNA with ribonuclease for 1 h at 37° C and the reaction continued for 2 h. Deoxyribonuclease sensitivity was determined by pre-incubation of the RNA template with deoxyribonuclease at 37° C for 1 h. The template and deoxyribonuclease were separated by repeated phenol extraction and ethanol precipitation followed by DEAE-cellulose column chromatography with an NaCl step gradient of 0·15 M, 0·35 M, and 0·7 M. The RNA fraction, eluting at 0·7 M NaCl, was precipitated with ethanol and then assayed for template activity. Lysozyme sensitivity was determined by co-incubation of human lysozyme in the reaction mixture. Sucrose gradient centrifugation was performed in an SW-25 rotor at 105,000*g* for 16 h. For the diphenylamine assay 2 mg of the deoxyribonuclease treated RNA was precipitated with cold TCA and assayed by the method of Burton[14]. Test of the rat liver RNA template for amino-acid acceptance was carried out with partially purified rabbit liver aminoacyl-tRNA synthetases. The reaction mixtures and methods of preparation of the synthetases were previously described[8]. The aminoacyl-tRNA synthetases used in these assays were limiting. Thus the amino-acid acceptance by the RNA was not a maximum.

Table 3. ENZYMATIC DIGESTIONS OF ^{3}H-TMP-LABELLED PRODUCT

Treatments	c.p.m./ml. minus background
Control, none	12,260
Ribonuclease, 2 mg/ml.	11,640
Trypsin, 1 mg/ml.	11,080
* NaOH, 0·5 N	7,670
Deoxyribonuclease, 4 mg/ml.	560

RNA dependent DNA polymerase reaction was carried out for 4 h as described in Fig. 1. The sample was then divided into 5 aliquots and treated with either water (control), ribonuclease, deoxyribonuclease, trypsin, or NaOH (0·5 N). The reaction was then continued for an additional 1 h. * The adjustment to 0·5 N NaOH terminated the reaction early and hence yielded lower counts.

Inhibitors of ALL Polymerase

M. Green (personal communications) has found that the rifampicin analogue N-demethylrifampicin, but not rifampicin itself, inhibits the RNA dependent DNA polymerase of the oncogenic RNA virions. The partially purified human ALL RNA dependent DNA polymerase is also markedly inhibited by N-demethylrifampicin and inhibited less by rifampicin (Table 4). If the presence of the enzyme is, in fact, unique to leukaemic or other neoplastic cells, its inhibition by these agents has obvious implications to chemotherapy.

Table 4. INHIBITORS OF ACUTE LEUKAEMIC LYMPHOBLAST RNA DEPENDENT DNA POLYMERASE

Treatment	Per cent of control
None	100
Rifampicin	
50 μg/ml.	102
200 μg/ml.	81
460 μg/ml.	60
N-demethylrifampicin	
50 μg/ml.	60
200 μg/ml.	42
300 μg/ml.	37
460 μg/ml.	0

The assay was identical to that described in Table 1.

Although the significance of this enzyme to the leukaemogenic process remains to be proven and a viral RNA active in templating the enzyme has yet to be demonstrated, the finding of an RNA dependent DNA polymerase in ALL lymphoblasts and the failure to find the same activity in normal lymphoblasts is consistent with a viral etiology.

On the other hand, the RNA template dependency of this polymerase could implicate a gene amplification role of the enzyme in biochemical cytodifferentiation, which could prove to be the basis of leukaemogenesis. Although differences in enzymes of human leukaemic cells compared with comparable normal cells have been sought for many years, there is little if any evidence for any qualitative differences. But there is suggestive evidence by molecular hybridization studies[15] and by comparative column chromatography[8] for the presence of different RNA species in human leukaemic cells and in normal cells. The presence of an RNA dependent DNA polymerase in leukaemic cells might be implicated in these differences.

We thank Dr B. Moss of the US National Institutes of Health for a generous gift of rifampicin and N-demethylrifampicin provided by Gruppo Lepetit. This work was supported by the US National Cancer Institute and Bionetics Research Laboratories, Inc.

Variability of Interchain Binding of Immunoglobulins

The variability of the interchain binding of light and heavy chains (the different human immunoglobulins is a puzzling feature of the covalent structure. The following articles describe the intercha binding of the three subclasses of mouse IgG and of the huma IgD class.

Interchain Bridges of Mouse IgG2a and IgG2b

THE four-chain structure of two heavy and two light chains, usually linked by disulphide bridges, is basic to immunoglobulin molecules, but differences in the number and position of the interchain bridges have been noted in the study of molecules of different human IgG[1] and IgA[2] subclasses. Thus the number of interheavy chain bonds in human IgG molecules may be two (in IgG1 and IgG4) to five (in IgG3); these bridges may be close to the bond to the light chain (in IgG1) (refs. 1, 3, 4)

Mice have three major subclasses of IgG (IgG1 or Igl IgG2a or IgG; and IgG2b or IgH) the biological properti of which have been reviewed[7]. Only IgG2a and IgG2 molecules fix complement, whereas only IgG1 molecul give positive passive cutaneous anaphylactic reactio when tested in a homologous (mouse skin) system. He we report studies on the sequences around the intercha disulphide bridges of two mice IgG2a (MOPC 173 ar 5563) and a mouse IgG2b (MOPC 141) myeloma prote obtained from transplanted tumours. The protei were purified from serum provided by Drs A. Mun (MOPC 141) and Fougereau (MOPC 173 and 5563).

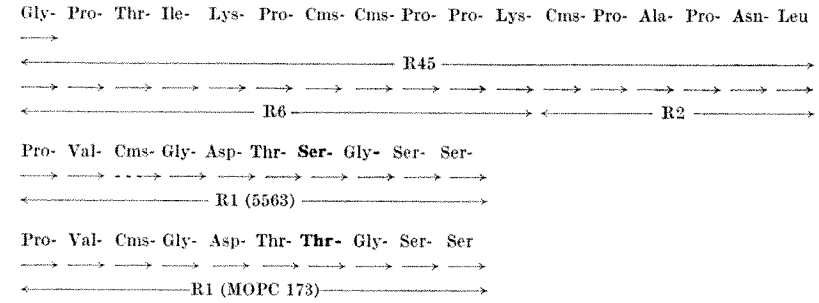

Fig. 1. Sequences of carboxymethylcysteine containing peptides obtained by partial reduction and carboxymethylation of IgG2a proteins 5563 and MOPC 173. The peptides were obtained by digestion with pepsin and trypsin. The sequence of peptide R1 was in fact established using the cysteic acid derivative isolated in diagonal experiments. Cms: carboxymethylcysteine sulphone.
Arrows indicate results of Dansyl-Edman procedure. Broken arrow indicates that the identification was uncertain.

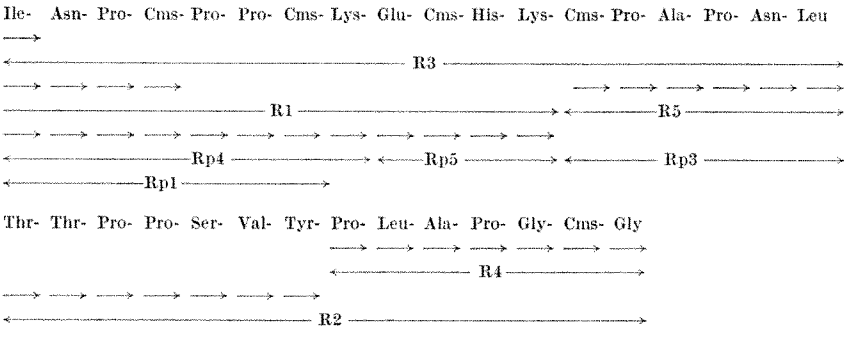

Fig. 2. Sequences of Cem-containing peptides obtained by partial reduction and carboxymethylation of IgG2b protein MOPC 141.

or probably more than 100 residues distant in linear sequence from it (in IgG2, IgG3 and IgG4 molecules[1]). These differences are in contrast to the otherwise close similarity between molecules of different subclasses[5,6], and may be important in mediating the different biological activities of the subclasses.

Interchain bridges were characterized by parti reduction and labelling with ^{14}C-iodoacetic acid[8], and t the diagonal procedure. In each case pepsin/trypsi digests were prepared and subjected to paper electr phoresis at *p*H 6·5, and selected peptides were purifie (before and after oxidation) at *p*H 3·5. After parti

reduction and labelling, the protein was re-reduced and alkylated with cold iodoacetic acid[9] to maximize the yields of carboxymethyl-cysteine containing peptides.

Labelled peptides obtained from IgG2a proteins 5563 and MOPC 173 are shown in Fig. 1; there was another peptide which was identified as the C-terminal sequence of the κ light chain[10]. The two myeloma proteins gave identical results except for a substitution of a serine for a threonine residue in peptide R1. This substitution may be a genetic difference between the two strains of mice on which the tumours were grown, serine being present in C3H mice instead of threonine present in Balb/c. Peptide R1 contains the half cystine residue involved in the binding of light chains. This was clearly shown in experiments using the diagonal procedure for the elucidation of disulphide bridges. The other half cystine residues present in peptide R45, R2 and R6 were present in the diagonal experiments in the absence of other cysteine containing peptides indicating that they are involved in interheavy chain binding. Six labelled peptides were obtained from the partial reduction of IgG2b protein MOPC 141. One was identified as derived from light chains by its characteristic electrophoretic mobility[10], and the others are presumably derived from heavy chains. Their sequences were established by the Dansyl–Edman method (Fig. 2). The sequence of peptide R3 was further studied after digestion with papain which gave rise to the peptides Rp1, Rp4 and Rp5 of Fig. 2.

The partial sequence of the latter peptide was established by Dansyl–Edman as

Pro-Leu-Ala-Pro-Gly-Cya(Asp,Thr_2,Ser_2,Gly_2)

It seems then that IgG2a molecules contain three interheavy chain disulphide bridges and IgG2b contains four. It is still possible, however, that in each case one pair of half cystine residues forms a very labile intrachain link. The sequences obtained are compared with homologous sequences from human and rabbit immunoglobulin molecules (Fig. 3). The comparison between the two mouse proteins is particularly interesting for this shows that, as in the human subclasses, there is wide variation in sequence in this area and that gaps are required to preserve homology. The comparisons are compatible with the concept that human and mouse IgG subclasses evolved recently and independently of one another[6].

Human and mouse IgG1 molecules (see communication on page 932) are so far unique in having the interheavy–light bond only a few residues distant from the hinge region. Other immunoglobulins (probably including a human IgM protein[12]) have the bond situated at the beginning of the constant region. The cystine residues are not in exactly homologous positions in the mouse (position 132) and human (131) IgG proteins, but the two different positions are homologous to two adjacent cystine residues (of which one or other binds the light

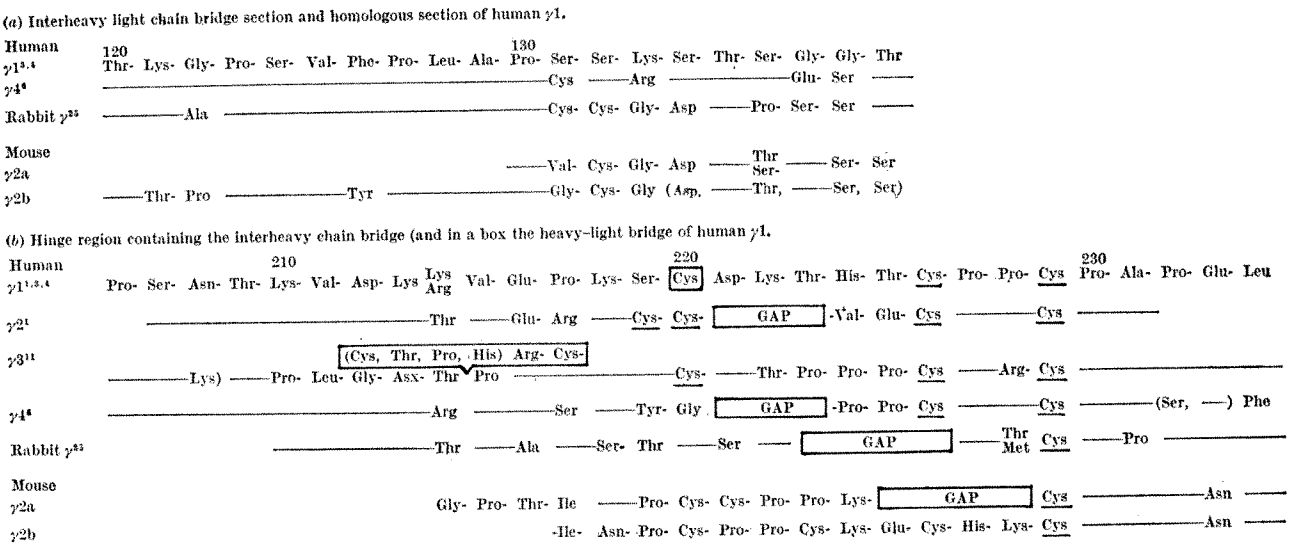

Fig. 3. Amino-acid sequences around interchain disulphide bridges or homologous regions in various immunoglobulins. Unbroken lines indicate identity to top line of sequence. Numbering is taken from ref. 4.

The disulphide bridging pattern of these peptides was established as follows. A peptic digest of the intact protein was fractionated by 'Sephadex G-75' chromatography and selected fractions were analysed by paper electrophoresis. The higher molecular weight material contained one major peptide which by amino-acid analysis and partial sequence was shown to be identical to R3. Its position on the 'Sephadex' column indicated that it occurred as a dimer. In addition a portion of the 'Sephadex' fraction was analysed without further paper fractionation giving an amino-acid composition very similar to the fractionated peptide. The experiment showed that no other peptide was disulphide bridged to any of the half cystine residues of R3.

From another fraction of the 'Sephadex' column a disulphide bridged peptide was identified by diagonal methods. This peptide contained the C-terminal end of light chains attached through a disulphide bridge to a peptide with an N-terminal sequence identical to R4. chain) in rabbit IgG[13]. The cystine residue in mouse IgG2a and IgG2b is in a position exactly homologous to the human IgD heavy–light bridge (see communication on page 934).

The biological importance of these differences in the hinge is unclear. The role of the disulphide bridges in complement fixation is still controversial, for Utsumi[14] and Kehoe and Fougereau[15] have isolated protein fragments containing the bridges but capable of fixing complement, whereas Schur and Christian[16] have destroyed complement fixing ability with reducing agents. The differences may allow different degrees of stretching of the Fab "arms" of the immunoglobulin molecule and thus influence antibody activity[17]. This could explain why certain antigens can apparently selectively stimulate production of particular IgG subclasses[18,19], although variable region sequences, and thus combining sites, seem to be capable of being shared by the different classes[20–24] and subclasses[6] of immunoglobulins.

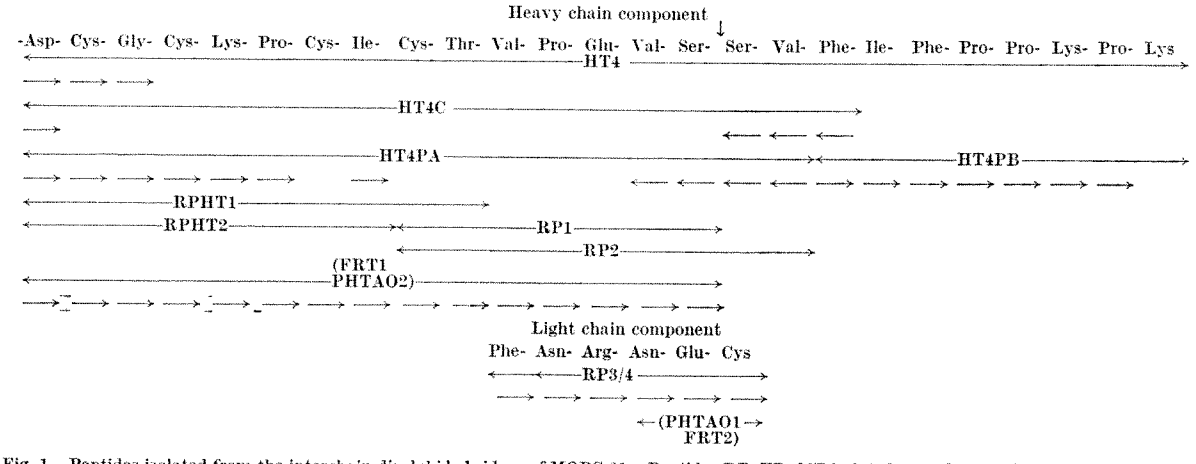
Interchain Bridges of Mouse IgG1

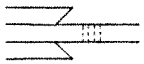
HERE we present a sequence containing all the interchain disulphide bridges of a mouse myeloma protein typed as γ1, κ(MOPC 21). As in human IgG1 the interheavy–light bridge occurs near the interheavy chain bridges in linear sequence.

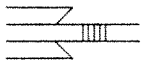
The myeloma protein was partially reduced with dithiothreitol and alkylated with ^{14}C-iodoacetic acid (IAA). From a peptic digest of partially reduced protein, seven radioactive peptides were obtained. RP3 and RP4 were identified as the C-terminal sequence of κ light chains. RP1 and RP2, although present in low yield, were analysed and partially sequenced. The other three peptides (not included in Fig. 1) were digested with trypsin to yield two smaller peptides (RPHT1 and RPHT2) which were characterized as shown (Fig. 1). From a tryptic digest of the totally reduced, alkylated heavy chains, two radioactive peptides were selected: HT4 and HT4C (Fig. 1). HT4 was digested with pepsin to yield two major peptides: HT4PA (radioactive) and HT4PB (non-radioactive).

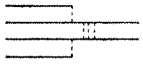
From a peptic digest of whole myeloma protein, a peptide (PH) was isolated and was unretarded on 'Sephadex G-50'. The peptide was digested with trypsin and the derivatives were fractionated by electrophoresis at *p*H 6·5. The fraction which had a mobility of 0·40 relative to aspartic acid gave rise, when oxidized by performic acid, to two peptides (PHTAO1 and PHTAO2). PHTAO1 was found to be the light chain C-terminal peptide. It was separated from PHTO2 only after destruction of the S–S bridges and therefore PHTAO2 must contain the half cystine residue of heavy chains which binds the light chains; but PHTAO2 contains four cysteic acid residues and it is not known which of the four is involved in this binding. PHTAO2 must also contain the interheavy chain bridge(s). This is so because it includes all the labelled residues of the heavy chain produced by partial reduction and ^{14}C-carboxymethylation in conditions leading to chain separation. In addition the rate of gel filtration through 'Sephadex' of the unoxidized peptide is significantly different from the oxidized derivative, indicating that it includes interchain bridge(s). It is likely that the three half cystine residues form interchain bridges, for they are very labile to reducing agents. The possibility of a labile intrachain bond between two of the half cystine residues has, however, not been excluded.

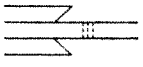
Confirmation for the sequence and also the location of the interchain bridges was obtained by isolating $F(ab')_2$ from a digest of the protein with pepsin at *p*H 4·0. The fragment was shown to have the Fab determinants by immunoelectrophoresis. By electrophoresis in sodium dodecylsulphate–polyacrylamide gels[1], the molecular weight before reduction was determined as 95,000. After partial reduction and alkylation with ^{14}C-IAA, two fragments were obtained of molecular weights 22,000 (light chain) and 25,000 (heavy chain fragment Fd′), both of which were shown by radio-











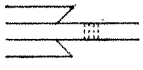


Fig. 1. Peptides isolated from the interchain disulphide bridges of MOPC 21. Peptides RP, FR, HT isolated as carboxymethycysteine derivatives, PH as cysteic acid derivatives. Arrows → indicate Dansyl–Edman results. Arrows ← show the sequential release of residues by carboxypeptidase A digestion. The vertical arrow shows the position of peptic split at *p*H 4·0 to yield the $F(ab')_2$ fragment (Fig. 2). Only those results considered essential for the sequence derivation are shown in this figure.

Table 1. INTERCHAIN DISULPHIDE BRIDGES AND SOME PROPERTIES OF THE SUBCLASSES OF HUMAN AND MOUSE IgG

Species	Subclass	Heavy chain	Electrophoretic mobility	Complement fixation	Skin fixation*	Suggested interchain disulphide bridge pattern
Human	IgG1	γ1	Slow	+	+	
	IgG2	γ2	Slow	+	−	
	IgG3	γ3	Slow	+	+	
	IgG4	γ4	Fast	−	+	
	IgG1	γ1 (φ)	Fast	−	−	
Mouse	IgG2a	γ2a (γ)	Slow	?	+	
	IgG2b	γ2b (η)	Slow	+	−	

* Results quoted are from tests on guinea-pigs.

Dotted lines for disulphide bridges indicate that evidence for interchain nature of bridges is incomplete.

References: for disulphide bridges see 2 (human), this and the preceding communication (mouse): for complement fixation and skin fixation see 3, 4 (human), 5, 6, 7 (mouse).

autography to be labelled (the 25,000 fragment being more strongly labelled). The $F(ab')_2$ molecule was partially reduced, alkylated with ^{14}C-IAA, then totally reduced and blocked with cold iodoacetate, and digested with trypsin. Two radioactive peptides were obtained—FRT1 and FRT2. The latter was the light chain C-terminal peptide and the former was at the C-terminus of the heavy chain fragment since it did not contain a basic residue in the C-terminal position and was a fragment of HT4 isolated from the intact heavy chain (Fig. 1). This established the position of the interchain bridges of MOPC 21 as being at the C-terminal end of the $F(ab')_2$ fragment and completed the sequence (Fig. 2).

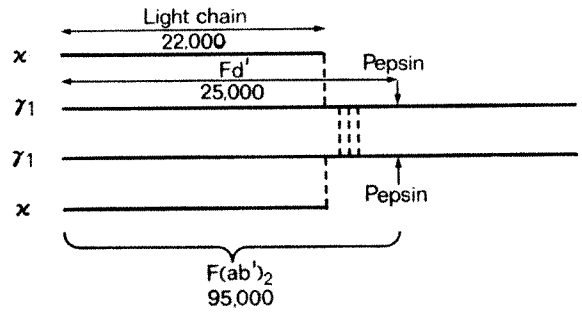

Fig. 2. Site of pepsin action at pH 4·0 on MOPC 21 and molecular weights of fragments.

Table 1 shows the arrangement of interchain disulphide bridges of the different subclasses of both human and mouse IgG together with some of their properties. Neither the proximity of the interheavy–light bridge nor the number of interheavy bridges is strictly correlated with some subclass properties such as the ability to fix complement or fix to skin.

In human IgG1[2] and mouse IgG1, the heavy–light disulphide bridge is very close to the heavy–heavy bridges, whereas in human IgG2, IgG3, IgG4[2] and mouse IgG2a, IgG2b (see preceding communication) they are probably separated by more than ninety residues. There are several possibilities as to how these may have evolved. It might be argued that there were two ancestral genes for the constant region of heavy chains before the divergence of mouse and humans. In one of the ancestral genes the interheavy–light bridge was close to, and in the other distant from, the heavy–heavy bridges in the linear sequence. With the divergence of the two species, one gene gave rise to the γ1 subclass in humans and mice, and the other to the γ2, γ3, γ4 subclasses in humans and the γ2a, γ2b subclasses in mice. In this case, the γ1 subclass in humans would be expected to differ from the γ2, γ3, γ4 subclasses more than γ2, γ3, γ4 differ themselves. But this is not the case—apart from the position of the heavy–light bridge γ1 and γ3 seem to be more similar than γ3 to γ2 or γ4. In addition γ1 of humans would resemble γ1 of mice more than it does other human γ chains, which seems not to be the case for the stretch of sequence shown in Fig. 3. It is more likely therefore[10] that these subclasses represent an example of parallel evolution in which the divergence of the γ1 from the γ2a, γ2b chains in mice is paralleled by the divergence of the γ1 from the γ2, γ3, γ4 chains in humans.

We thank Dr A. J. Munro for advice and for the myeloma serum and antisera. We also thank Mr F. Northrop for technical assistance.

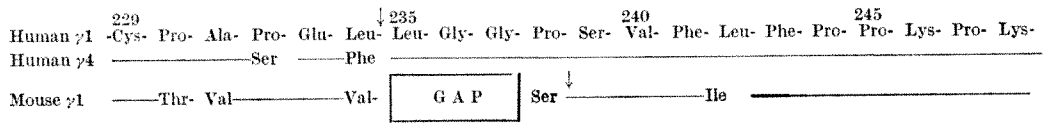

Fig. 3. Comparison of a sequence on the C-terminal side of the heavy–heavy bridges of human γ1 (ref. 8), γ4 (ref. 9) and mouse γ1. Numbering is as for human γ1. Unbroken lines indicate homology with top sequence. A deletion of three residues in mouse γ1 is necessary to preserve homology. Vertical arrows indicate positions of pepsin split to yield the $F(ab')_2$ fragment.

Interchain Bridges of Human IgD

IMMUNOGLOBULIN D (IgD), found as a minor component of normal sera and as a rare myeloma protein, conforms to the general pattern of immunoglobulin structure, consisting of two heavy and two light chains. The heavy chains of IgD (δ chain) contain antigenic and have physicochemical characteristics that distinguish them from other heavy chains[1,2]. We report here studies of the interchain disulphide bridges of an IgD myeloma protein which have revealed a single interheavy to heavy (H–H) chain bridge and single heavy to light (H–L) chain bridge which has homology with the H–L chain bridges in IgD heavy chains.

IgD (Er 1) was isolated from human myeloma sera collected by Dr E. J. Ernisse and provided by Dr W. Hijmans (University Hospital, Leiden). It was purified in the presence of 5 mM ε-aminocaproic acid by Pevikon block electrophoresis in 0·05 M barbital *p*H 8·2, followed by column gel filtration on 'Sephadex G-200' using 0·05 M phosphate, *p*H 7·2, containing 0·2 M NaCl. Chemical typing of whole IgD using the procedure developed for the IgG subclasses[3] revealed well defined characteristics (Fig. 1) distinct from IgG subclasses, the radioactive peptides L1 and L2 being characteristic of the C-terminal peptide of λ light chains, while the peptides H1 and H2 were derived from the δ chain.

Table 1. CARBOHYDRATE COMPOSITION OF IgD AND IgD HEAVY AND LIGHT CHAINS*

	L-fucose	D-galactose	D-mannose	N-acetyl-D-glucosamine	N-acetyl-D-galactosamine	N-acetyl neuraminic acid
Whole IgD	0·95	15·1	20·3	16·5	11·1	19·0
Heavy chain IgD	0·40	8·1	9·9	8·1	4·8	8·0
Light chain IgD	0	0	0	0	0	0

* Moles of anhydroglycose/mole of protein using molecular weights of 184,000 for whole IgD and 70,000 for IgD heavy chain.

Partially reduced IgD was carboxymethylated with 2-^{14}C-iodoacetate[3] and was fractionated by gel filtration on 'Sephadex G-100' equilibrated with 5 per cent formic acid to give heavy and light chains which moved as single bands on sodium dodecyl sulphate (SDS) polyacrylamide gel electrophoresis[4,5] and had indicated molecular weights of 70,000 and 22,000 respectively. Using these molecular weights, the molar specific radioactivity of the light to heavy chain was calculated to be 1 : 2·05 ± 0·2.

Carbohydrate analyses were made on IgD further purified by gel filtration on 'Biogel P6' equilibrated with 5 per cent formic acid. Gas chromatographic procedures were used to determine and identify the neutral[6] and basic[7,8] glycose components. The results are shown in Table 1.

The isolated heavy chain (60 mg) in 10 ml. of 5 per cent formic acid was digested with 2·5 mg of pepsin for 16 h at 37° C followed by digestion with 2 mg of trypsin in 1·5 per cent ammonium bicarbonate, *p*H 8·0, for 6 h at 37° C. Gel filtration of the product on 'Sephadex G-25' equilibrated with 5 per cent formic acid separated the peptides H1 and H2 which were purified by electrophoresis at *p*H 3·5 before and after performic acid vapour oxidation and by electrophoresis at *p*H 6·5. Sequence analysis of the peptides gave the results shown in Fig. 2. Papain digestion of H1 afforded valine and the peptides H1p1 and H1p2 (Fig. 2) which were isolated by electrophoresis at *p*H 6·5.

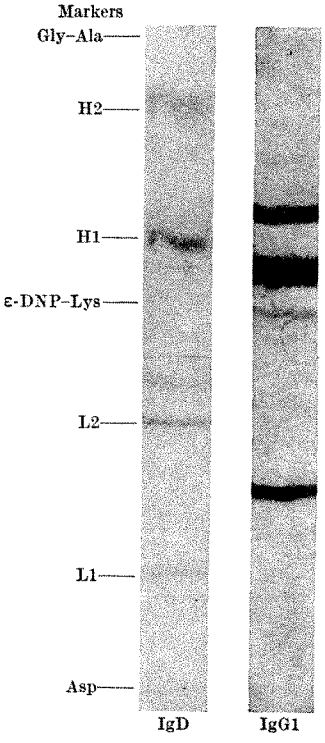

Fig. 1. Chemical typing of IgD (Er 1). Autoradiograph of the radioactive peptides from a peptictryptic digest of partially reduced and ^{14}C-iodacetate-labelled IgD (Er 1) compared by electrophoresis at *p*H 3·5 with peptides similarly obtained from an IgG1 type κ. L1 and L2 are two peptides derived from λ chains[10]: Pro-Thr-Glu-Cys-Ser (L2) and Cys-Ser (L1). Peptides H1 and H2 were also derived from isolated IgD σ chain. Electrophoretic mobilities at *p*H 3·5; L1, −1·03; L2, −0·44; H1, +0·21; H2, +0·62 (relative to glycylalanine = 1·0).

Peptides H1 and H2 were shown by the diagonal procedure to contain the half cystine residues involved in the H–H and H–L bridges respectively. A peptic–tryptic digest of whole IgD was fractionated on 'Sephadex G-50' in 5 per cent formic acid using ε-DNP-lysine marker. The pooled fraction containing peptides eluting before the marker was subjected to electrophoresis at *p*H 3·5. Two bands were selected (based on diagonal electrophoresis results) with mobilities of +1·05 and +0·78. (All mobilities at *p*H 3·5 are expressed relative to glycyl-alanyl marker = 1.) The band with the greater mobility contained a bridge peptide which, when oxidated by performic acid, gave rise to two derivatives having mobilities of +0·03 and −1·22 (*p*H 3·5 electrophoresis)

which were ninhydrin negative and isatin positive, indicative of N-terminal proline residues. Analysis showed that the purified peptides had the composition of the cysteic acid version of peptide H2 (Fig. 2) (mobility +0·03) while the other peptide (mobility −1·22) was identified as the C-terminal peptide of the λ chain. These define the H–L bridges.

Rabbits have chains containing both half cystine residues, but it is not known which of the two bonds to light chains. This raises the question of evolutionary pathways leading to the different locations of half cystine residues. One possibility is that the common precursor to Ig2b (mouse) and δ (human) was different from the precursor common to human γ chains. Other properties of δ chains,

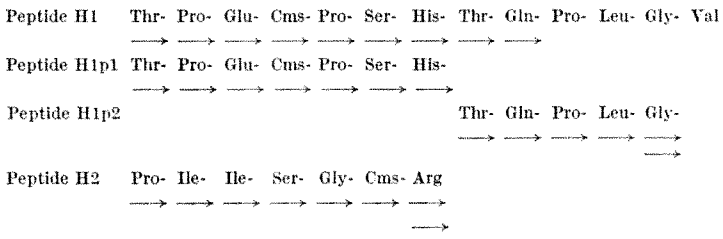

Fig. 2. Sequence of peptides H1 and H2 obtained from the σ chain of IgD myeloma protein. Cms, carboxymethylcystinesulphone. Arrows indicate Dansyl–Edman results. Double arrows indicate that the residue was obtained as free amino-acid at the end of the degradation procedure. Electrophoretic mobilities of peptides at *p*H 6.5 with respect to aspartic acid taken as 1·0–H1, 0·27; H1p1, 0·36; H1p2, 0; H2, 0·03.

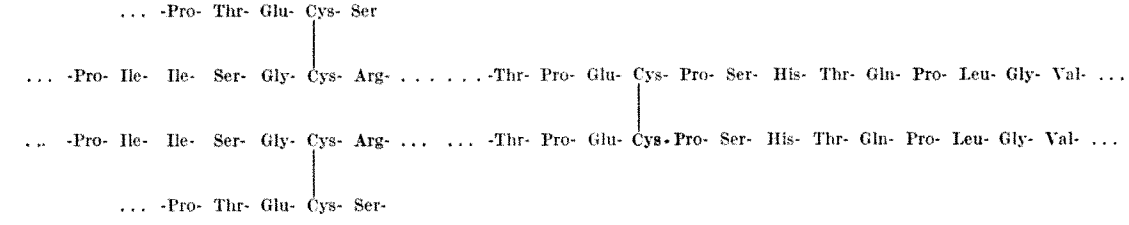

Fig. 3. Interchain bridges of IgD.

The second band (mobility +0·78) was subjected to electrophoresis at *p*H 6·5 (mobilities at *p*H 6·5 expressed relative to aspartic acid = 1) and a band (mobility + 0·03) which was yellow with cadmium-ninhydrin was cut out, oxidized with performic acid vapour, and subjected to electrophoresis at *p*H 6·5 to give a derivative (mobility +0·26) of altered mobility which like H1 was yellow with cadmium–ninhydrin and which had the same amino-acid composition as H1 (Fig. 2), thus locating the H–H disulphide bridge.

The results are summarized in the partial structure shown in Fig. 3.

Human γ2, γ3, γ4	-Pro-	Leu-	Ala-	Pro-	Cys-	Ser-	Arg-[13]
IgD (Er 1)	-Pro-	Ile-	Ile-	Ser-	Gly-	Cys-	Arg-
Mouse γ2b	-Pro-	Leu-	Ala-	Pro-	Gly-	Cys-	Gly-*
Rabbit	-Pro-	Leu-	Ala-	Pro-	Cys-	Cys-	Gly-[10]

Fig. 4. Sequence around the point of attachment of light chains to different heavy chains.

The presence of only one bridge between the heavy chains of IgD is unique in human immunoglobulins examined so far, but a single H–H bridge has been described in a rabbit IgG[9,10]. The presence of a single H–H bridge has been suggested in another IgD myeloma protein[11]. At this stage the interheavy chain bridge does not seem to have any convincing homology with known heavy chain sequences. The heavy to light bridge of IgD, on the other hand, is clearly homologous to the H–L bridges in other γ chains (Fig. 4). A comparison in fact shows that the half cystine of IgD occupies an identical position to the corresponding half cystine of mouse Ig2 chain, but one residue removed from the human heavy chains.

however, make this unlikely. The molecular weight of the δ chain determined by SDS-polyacrylamide gel electrophoresis was 70,000 which gives a value of 63,000 for the molecular weight of the peptide part of the heavy chain when the 12 per cent carbohydrate content is taken into account. This value is about 13,000 larger than the accepted value of 50,000 of γ chains and would represent an additional pseudo-subunit of about 120 amino-acid residues. SDS-polyacrylamide gel electrophoresis of glycoproteins with a similar carbohydrate content to IgD (Eril) gave determined molecular weights in close agreement with accepted values. More sequence data are clearly required for further clarification of the possible evolutionary origin of δ chains.

Kinetic experiments in a stopped-flow apparatus provide evidence for multi-electron steps in the reduction of oxygen.

CYTOCHROME *c* oxidase and the "blue" copper-containing oxidases (ascorbic acid oxidase, laccase and caeruloplasmin) are the only enzymes that catalyse reactions in which both atoms of molecular oxygen are reduced to water[1]. A great mechanistic problem with these enzymes is therefore the way in which one-electron oxidation of substrate is coupled to a four-electron transfer to oxygen. As stressed by George[2], in particular, it is unlikely that this reduction can occur by way of four consecutive one-electron steps. The principal basis for this contention is the fact that the relatively large, positive free energy change for the addition of the first electron to oxygen, coupled with the high standard oxidation-reduction potentials for the enzymes, would make such a reaction sequence extremely slow. For this reason, several authors have discussed the possibility that oxygen reduction with these enzymes may instead involve multi-electron transfer (see refs. 1, 3 and 4 for reviews). This suggestion does, in fact, receive support from some simple considerations—for example, the chemical composition of the enzymes, which shows that they all contain at least four potential electron-accepting sites[1,3,4]. In spite of this, no kinetic experiments designed specifically to test this hypothesis seem to have been carried out with cytochrome oxidase. On the other hand, kinetic investigations[5,6] have provided strong evidence for such a mechanism in the case of laccase catalysed oxidations. The chief basis for this interpretation was the finding that, whereas all reducible centres are reoxidized very rapidly in the fully reduced enzyme, fast oxidation does not occur with partially reduced laccase. The purpose of this article is to show that a similar experimental situation may be created with cytochrome oxidase. Also, in this case, reoxidation of the partially reduced oxidase is slow, requiring several minutes, despite the fact that Greenwood and Gibson[7] found the slowest step in the reoxidation of the fully reduced enzyme to have a rate constant of 700 s^{-1} in conditions where the oxygen concentration does not limit the rate.

The cytochrome *c* oxidase used in this study was prepared from beef heart particles of Keilin and Hartree by the method of Yonetani[8]. The final fraction was dissolved in 0·1 M phosphate buffer (*p*H 7·4) containing 1 per cent 'Tween 80'. It had a ratio of absorbances at 444 and 424 nm of 2·35 for the reduced enzyme. Cytochrome *c* was type VI from Sigma, and was used without further purification. Reduced protein was prepared by the addition of a minute excess of sodium dithionite, followed by dialysis under argon against 0·1 M phosphate buffer (*p*H 7·4) containing 10^{-4} M EDTA.

Stopped-flow spectrophotometry was performed in a Durrum–Gibson apparatus having an optical path of 2 cm and a measured dead time of 4 ms. Cytochrome *c* oxidation was followed at 550 nm or 520 nm, depending on the concentration used; the reduction and reoxidation of cytochrome oxidase was monitored at 605 nm, at which wavelength the contribution from cytochrome *a* dominates. The following values were used for the absolute extinction coefficients and the difference coefficients (ΔE) between the reduced and oxidized proteins, all expressed in terms of 1 mM concentration : reduced cytochrome *c* at 550 nm, 27·6; ΔE for cytochrome *c* at 550 nm, 20; same at 520 nm (ref. 9), 6·4; reduced cytochrome oxidase at 605 nm, 21; and ΔE for the oxidase at 605 nm (ref. 10), 11.

Earlier investigations of cytochrome oxidase with rapid reaction techniques have, on the whole, been concerned with the anaerobic reduction of the oxidized enzyme or with the reoxidation by molecular oxygen of the fully reduced enzyme[3,4,7,11,12]. On the basis of experiments[5] with another oxidase, laccase (or *p*-diphenol

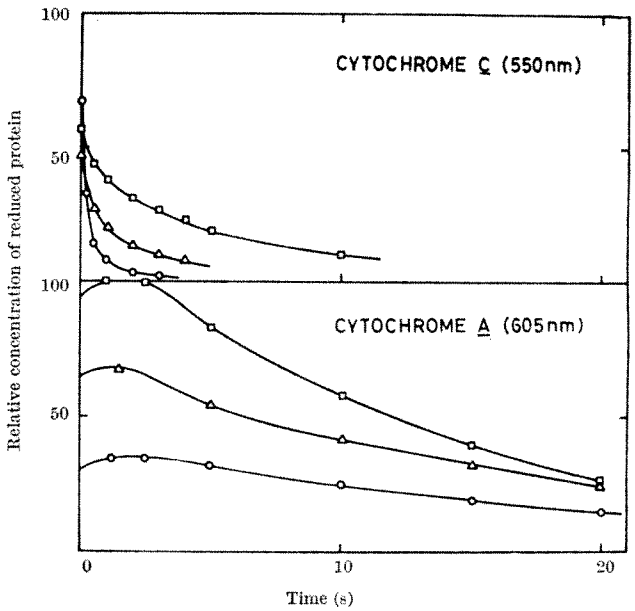

Fig. 1. The oxidation of ferrocytochrome *c* by cytochrome *c* oxidase in the presence of 280 μM oxygen. The reaction was carried out in 0·1 M phosphate buffer with 1 per cent 'Tween 80' at 20° C. Cytochrome *c* oxidation was followed at 550 nm and expressed as per cent of the original reduced cytochrome *c* remaining (top). The cytochrome *c* oxidase concentration (in terms of a unit containing one cytochrome *a* and one a_3) was 2·5 μM after mixing. The reduction and reoxidation was followed at 605 nm and expressed as per cent of the total cytochrome *a* reduced (bottom). Initial concentrations of ferrocytochrome *c* after mixing: ○, 0·9 μM; △, 1·9 μM; and □, 3·8 μM.

oxidase), we found it interesting to carry out transient kinetics measurements in the presence of both substrates, reduced cytochrome *c* and oxygen. In particular, we have worked with low cytochrome *c* concentrations to achieve a maximum concentration of partially reduced enzyme, the reoxidation of which by excess oxygen we could then follow.

Figs. 1 and 2 present some of our results. Those in Fig. 1 were obtained at constant oxidase concentration with varying concentrations of reduced cytochrome c (c^{2+}) close to and below stoichiometry with respect to cytochrome *a*. The curves in Fig. 2, on the other hand, were recorded with variation of both the c^{2+} and oxidase concentrations, which were, however, kept at a constant ratio with less c^{2+} than oxidized cytochrome *a* (a^{3+}). The fast phases in our progress curves agree well with the results from earlier kinetic studies[7,11,12]. Thus there is a rapid second-order reaction between c^{2+} and a^{3+}, as seen from the burst in product formation and the simultaneous reduction of the oxidase. The data in Fig. 2 at the two lowest concentrations of c^{2+} give a second-order rate constant for this step of about $3{\cdot}5 \times 10^6$ M^{-1} s^{-1} (see ref. 11). With higher concentrations of c^{2+} (data not shown) this initial phase was found to be followed by a steady-state period of c^{2+} oxidation. For example, a steady-state rate of 1·6 s^{-1} was found at 45 μM c^{2+}, in agreement with published turnover data[13] for Yonetani's preparations.

The most striking feature in our progress curves is the slow reoxidation of a^{2+}, which, in general, is not completed until several minutes after the exhaustion of substrate. This becomes most obvious at low concentrations of c^{2+}, which lead to the maximal formation of partially reduced enzyme (Fig. 2), but even at the highest cytochrome concentration used (45 μM) the reoxidation is considerably slower than what would be predicted on the basis of the published rate constant[7] for electron exchange between a_3^{3+} and a^{2+}. One way to interpret this by analogy with the situation for laccase[5] would be that rapid reoxidation only occurs with the fully reduced enzyme. But because the reduction of a^{3+} by c^{2+} is more rapid than subsequent internal redistribution, the reducing equivalents tend—towards the exhaustion of substrate—to be distributed on cytochrome *a* in different enzyme molecules. The formation of fully reduced enzyme therefore requires electron transfer between different oxidase molecules, and this limits the reaction rate.

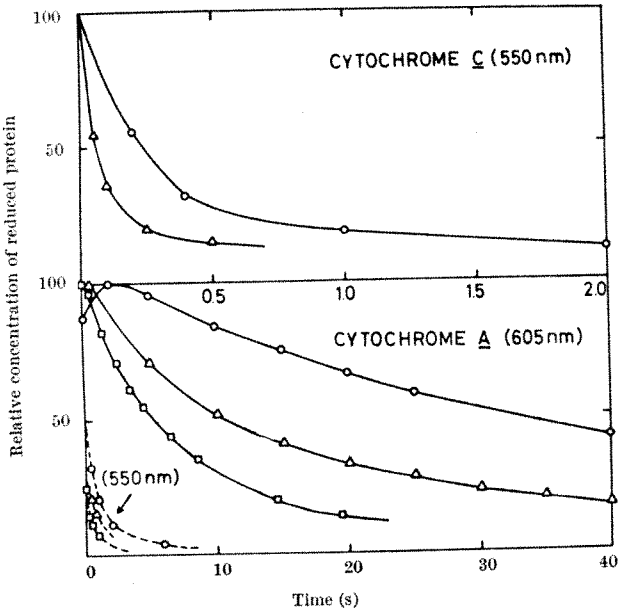

Fig. 2. The effect of the concentration of cytochrome *c* and cytochrome *c* oxidase on the reduction and reoxidation of the enzyme. The buffer, oxygen concentration, temperature and monitoring wavelengths were as in Fig. 1. The top part shows the fast phase in the oxidation of ferrocytochrome *c*, expressed as percentage of the original concentration of reduced protein (the data for the highest concentration are excluded, for too large a part of the fast change occurred within the dead time of the apparatus). The bottom part shows the same curves (dashed), including the one for the highest concentration, together with the reoxidation of cytochrome *a*, expressed as the percentage of the maximal concentration of reduced *a*, which corresponded closely to the initial concentration of ferrocytochrome *c* according to the total absorbance changes. Initial concentrations of ferrocytochrome *c* and oxidase (expressed as in Fig. 1), respectively: ○, 0·22 and 0·93 μM; △, 0·66 and 2·8 μM; and □, 2·0 and 8·4 μM.

In the kinetic experiments of Greenwood and Gibson[7], only trace amounts of cytochrome *c* and excess ascorbate were used to reduce cytochrome oxidase, and c^{3+} is an inhibitor of the enzyme[4], so that one might argue that the slow oxidation of a^{2+} is caused by the binding of c^{3+} to the oxidase. In such a case, however, the rate should increase with decreasing cytochrome *c* concentration, whereas the opposite is found (Fig. 2). As the concentration of oxidase is also decreased in the experiments of Fig. 2, the decrease in the rate of reoxidation in fact gives strong support for the suggestion that this is limited by intermolecular electron transfer. Calculations on this basis for the slow phases of reoxidation of a^{2+} all yield a second-order rate constant of $4{\cdot}4 \times 10^4$ $M^{-1}s^{-1}$, further strengthening this interpretation. This value is very similar to those obtained for electron exchange between some other redox proteins (unpublished results of B. G. M., A. Finazzi Agrò, C. G., E. A., M. B. and B. Mondovì).

Our experiments seem to require an abandonment of the concept that the reduction of oxygen by cytochrome oxidase occurs in four sequential one-electron steps. In the absence of more detailed information, we have assumed that only the fully reduced enzyme reacts rapidly with oxygen, but it would be sufficient for explaining our results to assume that rapid electron transfer from a^{2+} to a_3^{3+} requires two reducing equivalents. This would be analogous to present concepts about the "blue" oxidases[1], which assume that electron transfer from the "blue" type 1 copper ion only takes place if an additional reducing equivalent is available. This is thought to occur because the electron taken up by the initial acceptor (type 1 Cu^{2+}) is transferred to the two diamagnetic copper ions, which act as a cooperative two-electron acceptor.

Clearly, a more detailed picture concerning the steps by which oxygen is reduced to water in cytochrome oxidase requires more exhaustive kinetic experiments, utilizing the different spectroscopic and magnetic properties of four potential electron acceptors (cytochromes *a* and a_3, and the two copper ions). But we feel that our finding that the reoxidation of cytochrome *a* in partially reduced enzyme is slow, and limited by a bimolecular reaction between oxidase molecules—by analogy with the kinetic situation for laccase[5]—provides strong evidence that this process involves multi-electron steps.

A fellowship from the Royal Society under the European Programme (C. G.) and a short-term EMBO fellowship (B. G. M.) are gratefully acknowledged.

Reversion of Virus-transformed Cell Lines: Hyperploidy accompanies Retention of Viral Genes

by

ROBERT POLLACK*
SANDRA WOLMAN
ARTHUR VOGEL

New York University Medical School,
Department of Pathology,
New York

An increase in chromosome number accompanies reversion subtetraploid mouse cell lines from malignant transformed phenoty to growth-controlled normal phenotype. When growth control once again lost, the chromosome number drops back to the su tetraploid mode.

GROWTH control of a cell line is measured *in vitro* as a reversible cessation of cell division. Cell lines are maintained in culture by a periodic replacement of medium and serum. Populations with a degree of growth control will divide while sparse, but will cease to increase in number when they reach some cell density beyond confluence. Those cultures with maximum growth control cease dividing at the lowest cell density, that is at confluence. Populations with less growth control reach higher densities before stopping, and those with no growth control continue to divide until their medium is exhausted. Growth control can therefore be measured by assay of saturation density.

Permanent fibroblast cell lines derive from primary tissue cell populations by passage through three distinct phases of growth: an initial period of progressive rapid growth; a dormant period called crisis during which few cells are able to divide; and an extended period of rapid growth, as an established cell line[1,2].

Established cell lines are the descendants of the minority of cells able to divide through crisis. This defines the crisis as a period of selection, and in fact cell lines can be selected to have either high or low degrees of growth control[3,4]. Cell to cell contact seems to be the operative variable in this selection, for if cells are permitted to make contact during crisis, then a cell line will arise that has the ability to divide despite this contact, and such a line will retain little or no growth control[3-5]. Keeping cells from contact during crisis will yield a line with a very high degree of growth control, like the 3T3 mouse line[4].

In constant culture conditions, constant frequency of medium changes, and constant concentration of serum in the medium[6,7], saturation density is the parameter of a cell line that correlates best with its ability to grow into a tumour *in vivo*[3,8,9]. This point is shown clearly with the small polyoma and SV40 DNA viruses. These viruses induce a rapid loss of growth control in primary cells and in established lines of high growth control. Such cell lines, called transformed lines, are almost always more tumorigenic than their uninfected parent lines[3,9-12].

Reversion

The loss of growth control is reversible. By a choice of selective conditions, cell lines with high growth control (revertants) can be obtained from cloned populations with low growth control, including virus transformed cell lines. Revertants have been isolated by: (*a*) negative selection of transformed cells at high cell density with FUdR, a drug toxic to dividing cells[13]. Such cells are bigger than their transformed parents and look flat; (*b*) passage of transformed cells on cell layers fixed with glutaraldehyde[14], which presumably selects for cells with an altered surface that permits them to grow on this substratum; and (*c*) selection for hybrid hamster transformed lines with reduced chromosome complements[15] that have lost the chromosome(s) bearing the viral genome. Such cells are oriented and do not grow in agg Like the untransformed hamster line BHK21, howeve they grow to a high saturation density.

The viral genome, or part of it, is present in polyon and SV40 transformed cells[16-18]. Viral genes and the products must be responsible for the initial maligna transformation and viral genes are probably responsib for the maintenance of the transformed state in descen ants of the original transformant[19-21]. Thus the cel isolated by (*c*), which lack the viral antigens and a retransformable, arose as the viral genome was lost wi some chromosomes of the polyploid hybrid line[22]. Pr sumably, the genome was integrated into one of tho chromosomes. Similarly, hybrids between SV40-tran formed human cells and untransformed mouse cel originally retained the SV40 T-antigen, but lost it most human chromosomes were lost from the hybr cells[23]. By contrast, revertants of virus transforme cells isolated by methods (*a*) and (*b*) must retain at lea part of the genome of the transforming virus, becau they have viral T-antigen[13,14].

Revertant cell lines regain other phenotypic properti of untransformed cells in addition to increased growt control. Revertants isolated by methods (*a*) and (regain a completed cell surface glycoprotein, renderi them unagglutinable by a series of plant agglutinins th specifically agglutinate transformed cells and tumo cells[24,25]. Flat revertants of spontaneous[8] and polyon transformed[13,15] hamster cell lines isolated by (*a*) and (are less tumorigenic. Revertants of polyoma tran formed hamster cells isolated by method (*b*) are in son cases more tumorigenic than their parental transforme lines[26].

Stability of Reverted Cell Lines

Back reversion, or the reappearance of low growt control cells within a revertant population, occurs at low rate without experimental intervention in an population kept at maximum cell density for even a fe days. Only variant cells with diminished growth contr can divide at saturation, and in time their descenden overgrow the population[4]. Measured against this bac ground of spontaneous "transformation", stability the reverted phenotype varies with the selection systen Selections (*a*), (*b*) and (*c*) yield revertants as stable untransformed cells. That is, it is possible to sele dense variants from the revertant populations isolate by system (*a*) and these arise with about the same fr quency as such dense variants arise in untransforme populations.

Chromosomes of Transformed and Reverted Cell Line

Immediately on transfer from the animal to tissue cu ture, somatic mouse cells have forty acrocentric and tel centric and no metacentric chromosomes. They grad smoothly in size[27]. As the mouse cells in culture pas

Museums and the Seventies

In Britain in the past few weeks, the national museums have been up in arms about the proposal by the new Conservative Government that visitors should in future pay a small charge. As on all these occasions, students and other deserving categories of the population are likely to be excepted, although this is not yet certain. As far as can be told from Mr Anthony Barber's collection of economies in public expenditure, the objective is chiefly to bring some extra revenue into the Treasury so as to help implement the government's proposal to take sixpence off the income tax next April. The notion that visitors should pay to visit national museums, foreign to Britain, is nevertheless not one to be rejected out of hand. Certainly the experience of museums elsewhere does not amount to proof that entrance fees serve to turn people away. The Louvre is, for example, always as crowded as the National Gallery. What matters is that there should be easy devices for allowing those who cannot afford to pay or who should not be expected to do so to go in free. But if doctrinaire protests against the imposition of charges are dismissed, it does not follow that everything the government now proposes on museums should be endorsed. Indeed, the chief case against the new proposals is that they are or seem to be simply a device for raising what will in the end be only a very modest sum of money. They are unhappily not a part of the public strategy for national museums on which the government should be working.

The first thing to be said about the national museums is that they are chronically impoverished. Altogether, the government is spending £9 million a year on the national museums. The British Museum, one of the great museums of the world, costs the government a mere £3 million a year. Institutions such as the Science Museum get by on less than £700,000 a year, which goes a long way to explain why a museum that ought to be able to take the lead not merely in the collection of antiquities but in historical research in science and technology finds itself having to rely on the generosity of industrial companies for much of the material which it exhibits. The British Museum (Natural History) (which should really find some other way of describing itself) is a little better off and is indeed able to support a vigorous and distinguished research programme as well as to look forward to an extension to its building, but even here there is room for useful development. To be sure, given the long history of parsimony, the government is likely to pretend that its commitment to spend close on £10 million on buildings for the national museums in the coming decade is sufficient for the time being, and even its meanest critics will welcome the decision (of the previous government) to develop a new site for the library of the British Museum in Bloomsbury. But the more immediate need is for more money to spend on acquisitions and research. But if the government does eventually succeed in persuading the museums to levy entrance charges, the least that it can do is to make sure that the extra funds find their way not into Mr Barber's bottomless pit but into the current budgets of the museums.

This, however, should be merely the beginning. In the coming decade, there is a serious danger that the national museums in Britain will fail to keep pace with their peers abroad for lack of funds for sensible development. The picture galleries are the hardest pressed. At present, the art market is much more bullish than the budgets of the galleries. The result is that important acquisitions frequently depend on the generosity of well-wishers rather than on the will of the government to see that these institutions flourish. The same troubles afflict the other insti-

Artist's impression of the proposed extension to the British Museum (Natural History) in South Kensington. When completed in about 1973–4 the extension will provide storage space and research facilities for the museum's palaeontological department.

tutions on Mr Barber's payroll. Splendid collections are being developed less quickly than they should be. Libraries owe too much to the requirements of British copyright law that national libraries should receive a free copy of everything published in Britain, which in turn conceals the difficulty of keeping worthwhile collections of publications from abroad. Institutions such as the Science Museum cannot conceal their impoverishment in this respect. It is no wonder that Mr Barber's anxiety to collect some small change from those who visit these institutions should have served as a reminder that the museum service is seriously starved of working funds.

The truth is that in the decade ahead, these institutions should become even more widely recognized as centres of important research than they have been in the past. The Science Museum is a good illustration of this deficiency. Largely no doubt because of the straitened circumstances to which it has become accustomed, the museum has become a large and frequently overcrowded showcase with a small if distinguished appendage of historical research. Yet if the museum is to play a part in helping to develop the present stream of academic interest in the origins of the development of modern science, it will certainly wish for much more leverage than this. The ideal would be that the Science Museum should become as important a centre of academic research as the Natural History Museum has become. But the same principle applies to all the other institutions. The government must recognize that research is an indispensable part of the process of collecting objects of any kind, books, skulls or Grecian urns. In the long run, it may well be simpler to ensure that this doctrine is adequately recognized if responsibility for individual museums is transferred from the Department of Education and Science as such to the research councils and if, at the same time, the device of allowing responsibility for forward policy to rest with the body of trustees which has in the past given the British Museum (and the Natural History Museum) a delicious sense of independence could be extended to the other museum

None of this unfortunately will resolve the othe anomaly in the public posture of museums in th seventies—the question of how to present exhibitior to the public in terms that are meaningful to every body. The days have gone when scholars can b satisfied with the laconic collection of objects whic have become familiar aspects of museum exhibition The cases of stuffed birds serve no useful purpose fc research and scholarship, but also fail to excite th interest of the public. So should museums settle dow simply to be centres of research ? That would be t abandon one of their most important responsibilitie Indeed, as things have turned out, the need for devi ing ways in which museums can play a part in th developing public consciousness of important problem is more urgent than ever. Just as, towards the end c the nineteenth century, museums were able, fc example, to give Darwinism a fair wind, so now ther is a case for thinking that they have a part to play i drawing attention to the scientific foundations of great many important social problems. Why not, fc example, ask that museums should help to inforr people about the anthropological considerations whic play a part in contemporary racial problems ? Wh should not museums also help to provide a more vivi and objective appreciation of problems connecte with pollution ? It would, for example, be entirel proper to ask that every natural history museum shoul at this point in its history be concerned to demonstrat what ecology consists of and to prove that it is mor than merely "an attitude of mind". In short, ther is a strong case for asking that in the seventies museum should be increasingly concerned with matters of publ policy and that they should regard it as part of the public function to provide a continuing stream c comment on important public matters.

Evidently, important changes in the ways in whic museums are administered will be necessary if task like these are to be undertaken effectively and objec tively. There are, of course, great dangers in askin that museums should provide what may be considere a half-baked version of an analysis of contemporar problems. In the past few years, the inevitable tenc ency among those designing public exhibitions to len drama to their subjects has led sometimes to distortio and sometimes to exaggeration. The worthy effor made by museums in several nations to explain t visitors the role of space research in modern scienc have been wide of the mark. In an unexpected way museums are more prone to fall into the trap of over simplification than are popularizers of other kind: There are also dangers, unavoidable but not in them selves deterrents, in asking that museums should se themselves up to take a view one way or the other o some matter of public importance. This, however does not imply that museums should not try in th decade ahead to increase the value of their relatior ship with the outside world just as they must forg more durable links with the academic community On both counts, they need more money.

KUHN'S SECOND THOUGHTS

The Structure of Scientific Revolutions

By Thomas S. Kuhn. Second edition. (International Encyclopaedia of Unified Science. Vol. 2, No. 2.) Pp. xii + 210. (University of Chicago: Chicago and London, 1970.) 54*s* boards; 14*s* paper.

THE first edition of Professor Kuhn's well known book was issued in 1962. It immediately attracted attention and comment, as much for the novel questions it raised as for the particular doctrines that Kuhn was concerned to defend. For some forty years, the philosophy of science had been dominated by men trained in symbolic logic. Throughout this period, questions about the history and sociology of science had been set aside as devoid of serious philosophical implications. Kuhn's book had the great merit of compelling historians and philosophers, natural scientists and social scientists alike to pay more attention to the interconnexions between their respective specialities. In the subsequent eight years, his account of conceptual change in science as characterized by a sequence of "revolutionary" transitions from one "paradigm" to another—separating periods of "normal science", in which theoretical development proceeds cumulatively and without radical concept changes—has been the subject of much lively discussion.

The idea of theoretical "paradigms" was already familiar to philosophers of science and historians of ideas whose memories went back beyond Frege and Russell. It was originally introduced into the debate about the nature of physical explanation by Georg Christoph Lichtenberg, who was professor of physics at Göttingen in the mid-eighteenth century; it was revived by Ernst Mach and his successors in Vienna at the turn of the twentieth century, when Lichtenberg was for German-speaking philosophers the same kind of liberating influence that his British counterpart, David Hume, was in England; and it became the heart of the oral tradition of teaching about the subject in the later lectures of Ludwig Wittgenstein, as reflected, for example, in W. H. Watson's book, *On Understanding Physics*, and in due course introduced into the United States by Wittgensteinian philosophers in the 1950s.

In the discussions of men like Wittgenstein and Watson, there was no suggestion that the historical change from one paradigm to another was necessarily a "revolutionary" one; and it was this aspect of Kuhn's argument which—naturally enough—gave rise to most vigorous debate and criticism. What did his use of the term "revolution" imply? Was the transition from the pre-Copernican to the Newtonian world picture, for instance, a change so profound that a Ptolemy or a Buridan (say) could not even have talked intelligibly with a Laplace? At times, Kuhn's argument seemed to hint at rational discontinuities in the development of scientific thought so drastic that the very existence of natural science as a coherent rational enterprise seemed at stake.

Now, in this second edition, Kuhn gives us his second thoughts. For the most part, the book is reprinted unaltered. There are two brief textual changes in the body of the text, but the chief addition is an appendix (originally prepared for the Japanese translation) in which Kuhn discusses the objections and misunderstandings the book has provoked in the intervening years. The qualifications he now makes take much of the sting out of Kuhn's thesis; but at the same time they prompt the question, whether the original presentation of that thesis, in terms of an absolute contrast between "revolutionary" and "normal" phases in scientific change, was not a rhetorical exaggeration all along. At one point in the present appendix, for instance, Kuhn goes so far as to reinterpret this contrast as equivalent to the distinction between "propositional" changes within a given theory and "conceptual" changes in the basic terms of a theory; and this is a logical distinction, applicable to changes in a science going on at any stage, rather than a historical distinction between different kinds of phases in the growth of a science.

Looked at afresh, indeed, Kuhn's up to date account of scientific change turns out to be a much more orthodox empiricist affair than before—with successive scientific theories being designed to be more "predictive", more "specialized", more "elegant" and so forth—and the revolutionary aspect of the original thesis has largely faded into the background.

Whatever one's reservations about the original Kuhnian view, and whatever qualifications he now introduces into it, the virtues of the book remain; and many of the questions he raised in it will continue to occupy the centre of the discussion about conceptual change in the natural sciences. Instead of trying to turn the clock back, what philosophers and sociologists should now be doing is to take the argument further, and to analyse more exactly the detailed mechanisms of conceptual change within each theoretical change in a science whether propositional or conceptual or both, about which neither Kuhn's first nor his second thoughts have left us much the wiser. Meanwhile, it is a sufficient mark of the historical influence of the book that, in this respect, it has made an irreversible difference to the philosophical argument.

STEPHEN TOULMIN

A CLASH OF ARMS

March 4: Scientists, Students, and Society

Edited by Jonathan Allen. Pp. xxv + 177. (MIT: Cambridge, Massachusetts and London, September 1970.) 18*s* paper.

AT the Massachusetts Institute of Technology, on March 4, 1969, an open meeting took place. This little book is a record of the proceedings—the set speeches and some of the public discussion. What was it all about? The admirable "Historical Introduction" by Murray Eden explains how a heterogeneous group of students and faculty members managed to hold together long enough to appear on the same platform and talk on the same general theme—even if at cross purposes. In such a place as MIT, this was something of an achievement.

The theme is not, however, as broad as the title pretends. The key words are: USA, technology, academics—and, above all, war. Of their kind, the speeches are excellent; even W. G. McMillan manages by his utter sincerity to avoid sounding like a parody of the establishment patriot with a dirty job to be done. With each speaker in turn—Feigenbaum, the concerned humanist; Chomsky, the analytical critic; Weisskopf, the liberal "insider"; Rabinowitch, the internationalist; Mann, the radical "outsider" and so on—we nod our head and say "how true". All the parties to the issue are well represented; if you lack a philosophy, a programme and a leader, here is a supermarket where all the goods are clearly displayed for your choice.

But it is all so contradictory and confused. If this is the best that a bunch of academics can achieve on a serious topic, then we ought to look elsewhere for guidance. A mere confrontation of moral imperatives resolves nothing. War, as we have often been reminded, is too serious a business to be left to the generals; yet it cannot

be wished away by the expropriation of corporate capitalism, by international understanding, by political manipulation, by a strike of scientists, or by dodging the draft. If the academic community (does it exist?) is to exert any leverage for this vital reform of human society, then it must discuss and discuss, argue deeper and deeper, and arrive at a sufficient consensus to discover the crack into which to insert the crowbar. More little books like this, more position papers and cries from the heart, are not enough: we need long sustained thought; we need a sociology, a psychology, an economics—a whole science—of war. The appeal of direct action is that one knows the enemy; the simple emotions of loyalty to a cause, the very virtue of which "patriotism" is the norm, absolve us from scepticism, doubt and difficulties of thought. Nevertheless, the pen is the mightier weapon.

Writing as an Englishman, without personal involvement in the tragedy of modern America, I must sound altogether too detached. Perhaps we too are on the way to the same hell of technocracy, technolatry and technoclasm. But here again, careful analysis is needed; human behaviour is so extraordinarily non-linear that small differences of history and social structure may have entirely different consequences. We can learn some lessons about what not to do—for example, we must keep secret research off the campus—but will eventually commit our own brand of folly in our own immutable way.

In the end, I think Gar Alperovitz struck deep when he mentioned the insecurity that makes scientists frightened or competitive, rather than courageous against infamy. The moral trauma and social psychosis of which this book is a witness may perhaps toughen a new generation to stand beside the few—Bohr, Szilard, Franck, Rabinowitch—who neither turned aside nor gave way to despair, nor threw away their intellectual weapons in mad sorties, but fought on when they knew they could not win. The military metaphor, alas, comes all to easily to mind!

JOHN ZIMAN

INTERDISCIPLINARY CULTURE?

Science: The Center of Culture

By I. I. Rabi. (Perspectives in Humanism, Vol. 6.) Pp. xx + 155. (New American Library in association with World Publishing: New York and Cleveland, 1970.) $5.50.

PROFESSOR RABI has been aptly characterized as the *éminence grise* of the American scientific community. As an elder statesman of science, Rabi can look back on a distinguished and varied career. He was rewarded for his accomplishments as a physicist with a Nobel Prize in 1944. At the same time, he was emerging as an important military scientist through his work both at the MIT Radiation Laboratory and in the Manhattan Project. Rabi's political and professional stature continued to rise after the war. Not only was he the key figure in the development of the Brookhaven National Laboratory, but he held important posts in the government as well: for example, he was at different times chairman of both the Executive Office's Science Advisory Committee and the General Advisory Commission for the Atomic Energy Commission. Given such credentials, his book, *Science: the Center of Culture*, will undoubtedly attract a wide audience.

It is a slender volume, one in a series edited by Ruth Nanda Anshen under the rubric of "Perspectives in Humanism". The purpose of these works, according to the editor, is to proclaim the constancy of human values and the validity of metaphysical thinking. Only by operating on this level, we are told, will it be possible to transcend the "failures" of scientific humanism and socialism (which seek merely human ends) and to find the basis for a truly unified culture.

Within this framework, Rabi's book seems rather out of place. It is not really a book at all, but a collection of essays written either in the 1940s or during the past decade. Thus, not surprisingly, *Science: the Center of Culture* suffers from a sense of repetitiveness. It also can sound dated, as when Rabi hopes that students will one day get involved with political issues; the article which contains that statement first appeared in 1962. The author's reminiscences of his own career are, by contrast, fresh, engaging and, alas, all too infrequent. Yet in spite of these limitations, the reader is able to perceive how Professor Rabi's themes converge into a coherent thesis.

His principal concern is that modern society is bereft of "wisdom" largely because it has isolated science (and scientists) from the wider context of culture and politics. By cultural isolation, Rabi has in mind the divide which exists between natural science and the humanities. Although this is by now a well-worn theme, he is able to introduce some new illustrations of the phenomenon. (He likens, for instance, Bertrand de Jouvenel's attempt to speak about physics to that "of a Bronxville matron visiting an avant-garde Greenwich Village café—she is well meaning but not with it". But Rabi's most caustic remarks are reserved for American politicians, whom he describes time and time again as "scientifically ignorant" men.

For Rabi, scientific illiteracy is a tragic fact of modern life. He sees science as "the first of the liberating arts", one which can provide man with new knowledge, sound methods and a sense of freedom. His point about intellectual satisfaction is self-evident. As for methodology Rabi seems to be saying that important social and economic problems might be solved, if only we could view them with objective detachment. That the practice of science might give rise to a feeling of liberation is an argument related to the rate of technological change rather than to the attainment of personal fulfilment. Even at this moment, the author tells us, "we . . . have overcome the fear of innovation and experiment which seems to be innate in so many people". And, clearly, he believes that this attitudinal change represents an advance in human affairs.

The central problem thus becomes: how can science be integrated into essentially traditional patterns of culture and politics? On the cultural side, Rabi's proposals are too modest. He calls for greater interaction between specialists in humanities and the natural sciences, without indicating the motive forces or modes of communication necessary for the achievement of this programme. (He neglects the social scientists altogether.) His political reforms, on the other hand, are too ambitious and utopian. Here the elder statesman dreams of a Congress consisting of, in the main, freely elected (and scientifically literate) intellectuals.

The mention of politics in the United States is not wholly inappropriate here. Rabi's book bears the stamp of its national origins, not simply because it is addressed to an American audience, but because it reflects in two ways an ethos common to many American liberals educated in the interwar period. First, Rabi believes that all social and cultural problems, no matter how intractable, can be solved through sheer determination and hard work. ("We have the means; if only we had the will", and so on.) The second aspect—and it is closely related to the first—concerns Rabi's unquestioning faith in the durability and universality of social values. In the 1960s, however, the assumption of a politico-ethical consensus within America simply became untenable. One of the values most called into question, particularly by young radicals, was the very doctrine of *laissez innover* which Rabi himself has so ardently defended. Unlike the elder statesman, they (and I) are not prepared to accept the description of atomic and hydrogen bombs as the "natural consequences of the scientific knowledge at our disposal, and as such . . . inevitable".

PAUL GARY WERSKEY

PROGRESS AND ETHICS

The Sociology of Progress

By Leslie Sklair. (International Library of Sociology and Social Reconstruction.) Pp. xvi+272. (Routledge and Kegan Paul: London, November 1970.) 65*s*.

THIS book falls into two parts. The first, consisting of a brief history of the idea of progress, is competently enough done, but neither very original nor very profound. It serves chiefly as a setting for the more important second part, which is intended to establish, rather grandiloquently, "the" sociology of progress.

Here we start at once with the difficulty of definition. This is more than a verbal problem, for whereas for most other people working in the field progress means an immanent tendency for the system to "improve" in some sense to be defined, here it seems to be derived from an individualist basis, the desire of every human being for things to get better with him and to have his problems solved. This, of course, begs all the questions, such as the distinction between people's desire for progress and its actual historical experience, the success and effectiveness with which people pursue "progress" as against other aims, and the common situation in which the quest for "progress" by one group can be achieved only at the cost of regression by others. Indeed, because he maintains that all historical ideas are ideas of progress, and all history is the history of progress, certainly so in the case of knowledge and "probably" so in the case of social progress, it seems that the author has never considered the opposite, that is, regression, and the desire of powerful segments of all societies to turn back the clock. It is left to a footnote to make the proviso that "there have of course been periods in history when knowledge has stood still or has even been lost, but the general trend has been cumulative and progressive. I am speaking, of course, about the Western world", thus admitting that the sociology of progress is valid for only a small fraction of the historical experience, and not wholly valid even there.

The main claim to originality made in the book is the distinction between innovational and non-innovational progress. The discussion of this distinction which is intended to be central to the argument, makes heavy weather of it without advancing much beyond the Schumpeterian distinction between a new idea and its general acceptance, and ends up rather lamely with the admission that these two concepts are "ends of a continuum rather than twins in a dichotomy". The distinction between them is used for at least two major purposes. One is to show that non-innovational progress is progress of a kind, especially in the moral sphere, for example, the creation of a "better" society, nearer to an ideal that might well be an old-established one. The other is to claim that since the "institutionalization of science", which is here placed around the year 1800, the West has increasingly and mistakenly looked for, and worked for, the "innovational" kind of progress only.

Even if this concept is the most original, there is another which is more central to the argument. That is what is called the "sociological ethic", that is, the conversion of sociology into a normative science. One's sympathies are with anybody operating in this particular area where angels fear to tread; here the ethical criterion adopted is that of "meeting the needs" or "solving" the problem of individuals and societies: any society improving its performance in either of these two respects is, by definition, progressive. This, then, is the solution offered to all those who in the past have been sure of scientific and perhaps even economic progress, but never about moral progress. We can make statements about the moral progress of human society, and sociology can make value judgments, and the two are linked. Although the title of the book is about the former, one suspects that the author is more interested in the latter. Several value judgments are attempted on particular recent issues, such as the vast expenditure on the space programme at a time of widespread human poverty and disease, or the "biological time bomb", the tampering with genetic factors. On these, and other matters, the author has interesting, even if not original, things to say, but it is hard to see how "the" sociology of progress has helped him towards his views.

There are some glaring omissions in this approach, notably the a-historical attitude, in spite of some mention of relativism, and the failure to note the existence of classes and other opposed interest groups, whose "needs" and "problems" might conflict:—and then whose needs should have priority in the name of "progress"? There are also too many loose ends in the internal structure of the argument and the claims are consistently pitched too high, even in the title. But Mr Sklair is able to deal in an intelligent way with a number of the most urgent current problems, including the uses and abuses of science; and he deserves high marks for effort in introducing ethics into sociology.

SIDNEY POLLARD

HAPPY BIRTHDAY NRDC

Project X

The Exciting Story of British Invention. By Peter Fairley. Pp. 239+8 plates. (Mayflower: London, October 1970. 7*s* paper.

THE idea that Britain is uniquely bad at turning her inventions into new products is a persistent theme in Parliament and elsewhere. It is, in fact, a myth—fed by a lack of objective information and dependent on the Protestant view that inventiveness is a moral virtue not far short of godliness and cleanliness. In reality, almost all the important twentieth century technologies found their origins elsewhere; the motor car in France and Germany, the aeroplane in France and the United States, computers in the United States and Germany, electronics almost everywhere.

It is necessary to risk labouring this point because it was with the intention of remedying Britain's alleged weaknesses that the National Research Development Corporation was set up, and whose twenty-first birthday now provides a pretext for publishing this book. It opens with a wonderfully characteristic foreword by Mr Harold Wilson: "It is perhaps right that I should recall the opening words with which I commended the Second Reading of the Development of Inventions Bill to the House of Commons . . . the whole world will agree that this country has been second to none in the production of new ideas and of new inventions. But in the past we have sometimes been slow to put these ideas into full use, or even, occasionally, neglectful of them altogether, often with very grave results".

The history of NRDC since then should have laid such arguments to rest for ever. For all its success, it has handled very few inventions of the first rank. Only the hovercraft and the cephalosporin drugs qualify even for the middle rank in terms of economic impact or pecuniary return. Where, the curious might inquire, were all the major inventions which would otherwise have gone unexploited or abroad? The truth is that there weren't any. In spite of this, the illusions persist—proving once again that myth has a much greater hold on the public imagination than reality.

But what of the book? Peter Fairley is a science popularizer of the old school, somewhat overfond of a "gee-whizz" style of delivery. It is a style acceptable, even necessary, over the short course of half-column pieces in an evening newspaper, but it becomes trying over the long haul of a fattish paperback. Fairley does not shrink from quoting at length pieces originally published

elsewhere (usually in the *Evening Standard*) or great chunks in the rather different prose style of the NRDC itself. This contributes to a breathless impression, as if the book had been dictated during a bumpy taxi ride in between more important assignments. At one point several pages have been transposed, but one hardly notices.

For those able to pass over these defects, the book covers the ground adequately, and contains some scraps of new information. But I cannot help feeling that the NRDC deserved a better birthday present, both more measured and more thoughtful. This is a piece of public relations, and most people will recognize it as such.

NIGEL HAWKES

FOUNDATIONS OF SCIENCE

Nature and Nature's Laws

Documents of the Scientific Revolution. Edited by Marie Boas Hall. Pp. xii+381. (Macmillan: London, October 1970.) 100*s*.

THERE is much to be said for basing the study of the history of science firmly on documentary sources. Reading a learned analysis of a Shakespeare play is no substitute for the play itself and similarly it can be argued that it is better to read Newton directly than be satisfied with a secondary account of his work. Yet one cannot just sit down and read the *Principia Mathematica*; it might also be asking too much to expect a working scientist today to read right through Newton's *Opticks*. Although the carefully chosen experiments of Book I on the composition of white light may be numbered among the classics of the history of science, the most exciting (and influential) part of the *Opticks* is the "Queries" at the end, which are virtually independent of the preceding 300 pages. There is therefore a definite place for source books or selected readings in the history of science. Even quite a short excerpt here and there may provide an original flavour which would be sacrificed in the reported speech of a secondary account. Preferring a smaller number of fairly extensive excerpts, the editor of *Nature and Nature's Laws* has had to be more selective in the choice of texts, some translated especially for the book.

The object of the book is expressed in the sub-title: *Documents of the Scientific Revolution*. The author of any book on "the scientific revolution" is faced with a formidable task. Obviously something must be said of the contribution of Copernicus and also the powerful support given to his theory three generations later by Galileo; something too of the foundations of mechanics and the "Newtonian synthesis". Most historians of science would also agree on the importance of Francis Bacon and René Descartes and, if the science presented is not to be one-sided, there must be some physiology (William Harvey) and microscopy (Henry Power or Robert Hooke). Dr Hall has not only included all of these but also separate sections on pneumatics and optics for good measure. Adding texts on experimentalism and scientific organization, the editor gives a very good traditional picture of the seventeenth century. The trouble comes when she bravely tackles the problem of chemistry, the crucial period of which was unfolded a century later. It is presumably in order to be able to include Priestley and Lavoisier that Dr Hall defines the scientific revolution as a series of events occurring between about 1500 and 1790. Wishing to give full coverage to the seventeenth century without omitting the "chemical revolution" the editor leaves a large gap in the eighteenth century. Perhaps some of the earlier depth could have been sacrificed in order to include something by such diverse but important figures as Linnaeus or Buffon, Black or Hutton, Franklin or Boscovich. It is not true that after Newton's death in 1727 there was complete paralysis in science. A period of consolidation in mechanics and astronomy was accompanied by important advances on a broad front from electricity to geology. If these sciences are not included here it is because historians of science are not in complete agreement on the meaning and extent of the scientific revolution. The editor herself agrees that the term embraces a series of conceptual changes in different branches of science. A study of the circumstances in which conceptual change occurs in science is still one of the most fascinating of all problems facing historians of science.

The truth is that it is impossible to do full justice to the emergence of modern science within the covers of any one book and the editor is the first to admit this. Her introductions to the readings are authoritative and well written. The choice of texts shows some originality and fulfils admirably the aim of presenting a survey of

THE TOWER THAT FONTANA BUILT

This is the timber tower that the Italian engineer architect Domenico Fontana built on either side of the Vatican obelisk to move it in 1586 from its place in the Circus of Nero 275 yards to its new position in front of St Peter's in Rome. Fortunately for the history of engineering, Fontana made a meticulous record of the planning and execution of the colossal operation to move this giant monolith—the largest entire obelisk outside Egypt (it weighs 361 tons)—and his feat is told by Bern Dibner in *Moving the Obelisks*, a book which was first published by the Burndy Library in 1952 and which has been recently reissued as a paperback by MIT Press (Cambridge, Massachusetts and London, July 1970. 19s). The book has other fascinating contemporary engravings of this move, together with accounts of the different methods used later to transport the Paris, London and New York obelisks.

some important aspects of the emergence of modern science. If the book could be made available as an inexpensive paperback it could be very useful for students. In its present form it can be recommended as a valuable addition to the bookshelf of the scientist who recognizes the historical dimension of his profession or, through commendable curiosity, seeks some insight into the ideas of those who unlocked the gates to the modern world.

MAURICE CROSLAND

D'ALEMBERT'S ENLIGHTENMENT

Jean d'Alembert

Science and the Enlightenment. By Thomas L. Hankins. Pp. viii + 260. (Clarendon: Oxford; Oxford University: London, June 1970.) 70*s*.

THIS book is the first full-size study of one of the most influential personalities of the French enlightenment, who is also a major figure in the history of mathematical physics. There has been no lack of able investigations of particular aspects of this colourful period of French history, but nobody so far has had the pluck to attempt a synthetic account of the encyclopaedist's achievements in the field of science. For the successful accomplishment of this task we have to thank the flourishing American school of history of science, which combines rigour of method and soberness of judgment with unequalled efficiency in collecting and handling material evidence.

Jean d'Alembert is a revised version of a doctoral thesis, and it inevitably exhibits, together with the solid qualities of the school, the usual imperfections of the beginner's effort. The author has absorbed an incredible amount of information and not quite digested it: the presentation of his findings would gain by pruning and his style by more directness and a lighter touch. All his reading of the pithiest writings of which French literature can boast has not affected his own clumsy rendering of their contents; and disgraceful mistakes in unchecked French quotations reveal that French grammar may be as tricky as French wit is inimitable. Such minor blemishes, however, do not detract from the general excellence of the work. In the first place, the abundant and accurate bibliography, the wealth of well-ordered material (some of which is published here for the first time), the completeness and thoroughness of the discussion will give the book lasting value as a work of reference, not only about d'Alembert, but about his times and the history of the problems he investigated. Apart from this more technical aspect, the author's survey of his hero's thinking and achievements makes fascinating reading.

For all his weaknesses—compared with Euler's supreme virtuosity—d'Alembert ranks as one of the founders of the modern methods of mathematical physics, which were developed to exquisite perfection by his immediate disciples, Lagrange and Laplace. (Excellent reprints of d'Alembert's principal scientific works are available, incidentally, from Editions Culture et Civilisation, Bruxelles.) Still more important is the part d'Alembert played, together with Diderot and Condillac, in laying the epistemological foundations of science, its "metaphysics", as they called it then. On all these points, Hankins, even when he is not very original, has interesting views, always supported by first-hand evidence. Especially valuable is his analysis of d'Alembert's indebtedness to Descartes through the channel of Malebranche (and not, of course, through the diehard Cartesians of strict observance). He also throws light on the deep-seated difference between d'Alembert and Diderot on the question of the significance of mathematics for natural science—still a bone of contention today among theoretical physicists.

As regards the controversial problems raised by d'Alembert's *Traité de Dynamique*—his elimination of the concept of force, his summary dismissal of the *vis viva* dispute as a verbal quarrel, his way of handling infinitesimals—he does not shrink from the difficult task of retracing their history in order to establish d'Alembert's position with respect to the views of his predecessors; surprising as this may seem, he is here breaking new ground—so much is written, so little known about the course of Newton's or Leibniz's thinking on dynamics! Hankins should therefore not be blamed if his discussion at this point makes a somewhat sketchy impression: it gives at any rate a most instructive first orientation. Altogether, what the book lacks in brilliance is more than made up by the careful and intelligent treatment of its ambitious programme: it does draw a convincing portrait of d'Alembert.

L. ROSENFELD

A GENTLEMEN'S HOBBY

The Common Scientist in the Seventeenth Century

A Study of the Dublin Philosophical Society, 1683–1708. By Theodore K. Hoppen. Pp. xii + 297. (Routledge and Kegan Paul: London, October 1970.) 55*s*.

IT is useful to be reminded that great things start from small and obscure beginnings; and that this is as true of science as of anything else. It is by now well known to historians that the Royal Society itself was a fragile thing in its early days. Newton rescued it and made it a club fit for gentlemen, but the sort of Royal Society we would recognize now was, as the term "scientist" itself, a creation of Victorian times. In this work, T. K. Hoppen recounts the history of a society that never managed to strike roots. It was, in fact, a brave venture by William Molyneux and a few lesser *virtuosi* in Dublin. It died when Molyneux's interests were diverted, and flickered briefly into life again when his young nephew Samuel had a temporary interest in philosophy.

Whether there was then a "common scientist" is a question of some significance for the history of the period. It is true that there were no giants among the Dubliners. Their contributions are the common sort of gentlemen's amateur natural history, experimental philosophy, mechanical arts and medical experience, that filled all the "philosophical" journals of the time. But the failure of the ordinary members even to keep the society going is significant. It cannot be blamed on the colonial situation of Dublin, for the parallel society in Oxford fared no better. They were not "scientists" but gentlemen with a hobby; and the realization of Bacon's great dream was largely in the hands of such men, in Britain at least, until the industrial revolution.

J. R. RAVETZ

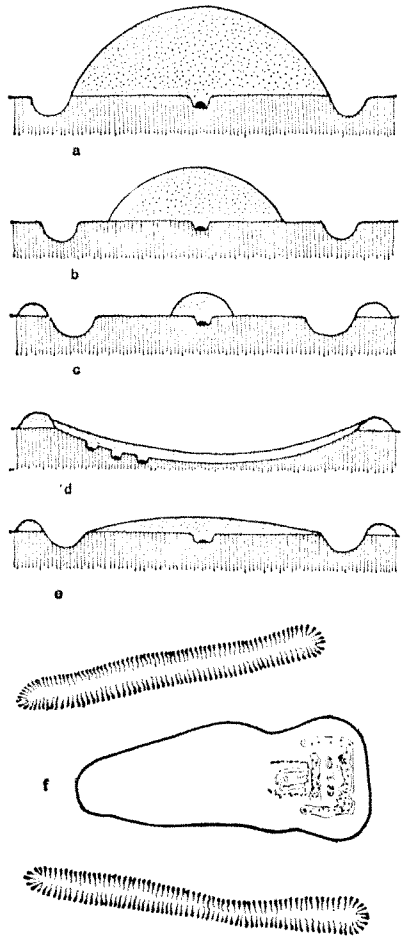
NEOLITHIC BURIAL MOUNDS

The Earthen Long Barrow in Britain

An Introduction to the Study of the Funerary Practice and Culture of the Neolithic People of the Third Millennium BC. By Paul Ashbee. Pp. xvi + 208 + 24 plates. (Dent: London, September 1970.) 126*s*.

EARTHEN long barrows were first studied as an archaeological category by John Thurnam in 1868, in his famous paper in *Archaeologia* entitled "On Ancient British Barrows, especially those of Wiltshire and the adjoining Counties. Part I: Long Barrows". Since then there have been many general studies such as that of Piggott, and regional studies such as those of Crawford, Grinsell, and Phillips; but it is not until this present book that we have been given a detailed and complete account. Mr Ashbee, who has already given us *The Bronze Age Round Barrow in Britain* (1960), and *The Fussell's Lodge Long Barrow* (1966), now puts us further in his debt with this

authoritative, careful, and clear survey of an important aspect of British prehistory in the fourth and third millennia BC.



This is a well produced and expensive book, and is well illustrated with maps, plans and photographs. The use of upper-case lettering and the over-reduction of some maps and diagrams (for example, Figs. 1, 2, 15–18, 58) make them unattractive and difficult to read without a magnifying glass. Ashbee lists all the earthen long barrows known up to 1967 and many he mentions have not yet been published in full. The book has been a long time with the printers: two new earthen long barrows have recently been discovered in eastern Scotland, and in its first season of excavation of one of them, the Department of Archaeology of the University of Edinburgh, under Professor Piggott, discovered features very like those described by Ashbee from southern Britain. We are all caught up by the progress of archaeological discovery, and by the fluctuations in our assessments of carbon-14 dates. Twenty-five years ago few writers would have dated any of the British earthen long barrows as early as 3000 BC. Now Ashbee, from ^{14}C dates, gives the range as between 3500 and 2000 BC, but bristlecone pine recalibration suggests that the earliest long barrows date from before 4000 BC.

Ashbee believes that the earthen long barrows in Britain are part of a north European Neolithic heritage of long graves, long mounds, and mortuary houses, and he cites a wide variety of parallels from the long barrows of Brittany to the Kujavian tombs of Poland: he has been assiduous in his continental survey and very properly includes Bonnières-sur-Seine, Stein, Konjens Høj and the north German boulder-bounded long barrows. He must surely be right in this view and also in seeing the sepulchral earthen mounds as funerary versions of long houses such as were built and lived in from eastern and central Europe to the low countries in the fifth to third millennia BC. He is not dogmatic in the statement of his views, but he is persuasive. This is, anyhow, an over-cautious book: its subtitle is "An Introduction to the Study of the Funerary Practice and Culture of the Neolithic People of the Third Millennium BC"; but he deals only with earthen long barrows and eschews comment on their relation with the megalithic long barrows.

At one moment he throws caution to the winds in claiming that the great grave found by St Patrick at Dichuil was a long barrow. I suppose it just could have been but the texts are equivocal. But we are grateful to him for reminding us of this curious account, and also for publishing portraits of Thurnam and Greenwell, his early predecessors in the study of non-megalithic long barrows in Britain.

GLYN DANIEL

ARCHAEOLOGY FROM A–Z

Types of barrows (round or elongated mounds covering one or more burials) found in Britain drawn by Judith Newcombe for *A Dictionary of Archaeology* by Warwick Bray and David Trump (Allen Lane (The Penguin Press): London, November 1970, 45*s*). The sections show (*a*) bowl barrow; (*b*) bell barrow; (*c*) disk barrow; (*d*) pond barrow; (e) saucer barrow; and (*f*) plan of Nutbane long barrow.

MAN AND THE EARTH

The Dominion of Man

The Search for Ecological Responsibility. By John Black. Pp. vi+169. (Edinburgh University: Edinburgh, July 1970.) 30*s*.

AT the beginning of this thoughtful and unusual book Professor Black quotes a definition of progress by a twentieth-century geographer: "increasing ability to dominate the forces of nature". He identifies the convictions that man's role on Earth is to exploit the rest of nature to his own advantage and that human populations will continue to increase as those ingredients of the western world-view primarily responsible for the ecological crisis about which so much is being talked and written at the present time. These convictions belong to the class of basic presuppositions which usually remain unquestioned although they underlie a large proportion of our thoughts and actions. Black sets himself the interesting task of tracing these particular presuppositions to their origins, and his search leads him back to the Judeo-Christian element in our western world-view and to the biblical accounts of the creation.

There are two such accounts in the Book of *Genesis*, reflecting alternative ways in which "the original mythical material was hammered into theological shape". The Priestly version of the first chapter states: "so God created man in his own image . . . and God said unto them, be fruitful and multiply, and replenish the earth, and subdue it; and have dominion over the fish of the sea, and over the fowl of the air, and over every living thing that moveth upon the earth". Black finds here the essential clues to the development of the western attitude towards man's relationship to nature. Increasing scientific knowledge may have made it impossible to accept this account of creation as literally true, but its effect on our world-view has nevertheless persisted.

The earlier Jahvist version of the creation myth appears in the second chapter of *Genesis*. In it the sequence of creation is quite different from that in the Priestly version in which man arrives last, after plants and all other animals. In the Jahvist version God made the Earth, then man, then a garden for man to live in. Only subsequently were animals and birds created as companions for man. They proved not entirely adequate for this

purpose and God eventually made woman. In this version man is nowhere given dominion over the animals.

Black suggests that the existence of these opposing views of man's relationship to animals may be evidence of an ambivalence extending at least as far back as the compilation of *Genesis* and persisting today. It manifests itself as a dualism in attitude towards the totality of other living organisms: the drive to control and dominate against a sense of the majesty and mystery of nature.

Subjugation of nature may have seemed to the Hebrew tribes the only means of permanent survival in their hard semi-arid environment. It is not surprising that God's injunction to them to control and dominate became an emphatically recurrent theme in their literature and part of their enduring contribution to the western world-view. But unrestrained exploitation of nature leads to disaster, especially in environments as fragile as that of the Hebrews. There was need therefore for an effective system of checks on over-exploitation. This was provided among the Hebrews by the concept of man's responsibility to God for the proper management of the Earth so as to avoid any diminution of its productivity. It may be supposed that the idea of stewardship would have found favour amongst those holding that other view of man's relationship to nature implicit in the Jahvist version of the creation story. And, in so far as the opposing views reflect a persisting dualism in human reactions to nature, it is intelligible that the compromise-concept of stewardship and accountability to God should have retained a place in orthodox Christian thought. "The end of man's creation," wrote Chief Justice Sir Mathew Hale in 1677, "was that he should be the vice-roy of the great God of Heaven and Earth; his Steward, Villicus, bayliff or farmer of this goodly farm . . . and hereby Man was invested with power, authority, right, dominion, trust and care . . . to preserve the face of the Earth in beauty, usefulness, and fruitfulness."

Man's present situation is that he has retained the basic presupposition that his role is to dominate and exploit the world of nature but is rapidly losing any effective sense of accountability to God for its proper management. At the same time, to be fruitful and multiply continues to be thought by many a right if no longer a duty. The result is that the ancient moral checks on over exploitation are becoming lamentably ineffective. They might by now have been replaced by new checks securely based on increased ecological understanding and on rational population planning, but short-term economic and nationalistic considerations too often gain the upper hand in any conflict over planning the utilization of natural resources. Black can offer us no certain prospect of reaching a stable relationship between man and nature within the framework of our existing society. So far, western civilization has failed because we have been unable to "engender a feeling of responsibility for the use to which we put our control over nature". This book should make all its readers ponder on the likely consequences of continued failure.

A. R. CLAPHAM

GEOGRAPHICAL ENQUIRY

Explanation in Geography

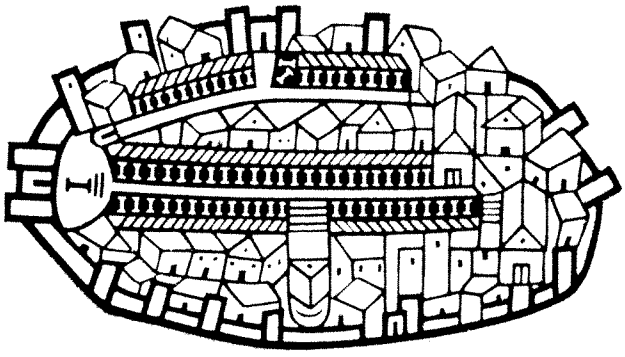
By David Harvey. Pp. xx+521. (Arnold: London, November 1969.) 65*s*.

DR HARVEY's book appears thirty years after Hartshorne's *The Nature of Geography* sought to define the purposes and scope of geographical enquiry and the place of geography among the sciences. There has been growing dissatisfaction in recent years with Hartshorne's analysis, derived from the writings of Kant and Hettner, of geography as the study of the areal differentiation of the Earth's surface. At least in part this dissatisfaction has resulted from the growing popularity of quantitative methods in a subject in which their use had previously been uncommon: William Bunge's *Theoretical Geography* (1962) was the first, rather erratic, indication of the changes in purposes and methods resulting from the quantitative revolution.

Explanation in Geography is thus a timely and important book. Harvey seeks to bring order out of the diversity of both traditional and recent geographical work by concentrating on the logical structure of explanation. In so doing he looks for guidance not to the work of geographers themselves, as did Hartshorne, so much as to the work of philosophers of science and of students in neighbouring disciplines. He takes the deductive model of Hempel and Nagel as his point of departure, and in a wide-ranging survey considers the nature of theories, laws and models; the use in theory-construction of mathematical, geometric and probability languages; problems of observation, measurement, classification and data collection; and, finally, alternative models of explanation, including causal, temporal, functional and systemic models.

Unlike *The Nature of Geography*, this book is not directly concerned either with the objects or objectives of geographic study, nor with the place of geography among the sciences. Harvey draws a sharp distinction between the philosophy and the methodology of the subject, and confines his treatment to the latter. The resulting lack of a philosophical framework leads to difficulties: the concluding discussion of alternative modes of explanation, for example, seems eclectic and undiscriminating, and no clear prescription for geographical enquiry emerges. Harvey is more concerned with exploring alternatives and their implications, rather than with defining the structure and bounds of the subject itself. The absence of such a structure is most apparent when he discusses the possibility of indigenous theory in geography. He suggests that such indigenous theory may be largely geometrical in origin and to do with spatial form, in contrast to the process or temporal theories derived from other disciplines such as economics or geology. But his own terms of reference prevent him from adequately discussing how far such indigenous theory is intrinsically geographical, and to what extent it must be further defined in terms of object and scale.

This book is, without doubt, one of the two or three most important to have appeared in geography since Hartshorne's in 1939. It does not claim to be definitive, but it clarifies the problems which have developed in recent years and suggests a variety of solutions. New problems also emerge. Kuhn's views on paradigm change, with their implications for the history of geography itself and for the way in which geography as a discipline functions, are perhaps too lightly accepted, by Harvey and by others. Harvey's book is, in fact, important because the problems it raises extend to all fields of geographical enquiry. Harvey himself likens his aim to establishing the rules of cartography before beginning to create a map: he has now made it possible to go back and reconsider the problem which Hartshorne hoped to solve, that of the extent and nature of the territory to be mapped.



D. R. STODDART

PALESTINE AND ITS PEOPLE

Atlas of Israel

Cartography, Physical Geography, Human and Economic Geography, History. Pp. 296. (Survey of Israel, Ministry of Labour: Jerusalem; Elsevier: Amsterdam, 1970.) 1,092*s*.

HAD it consisted merely of a set of maps, this book, for all the splendour of its production, could hardly have qualified for review in a scientific journal. But the Elsevier definition of an atlas has always been generous

Jerusalem fragment of Medeba map of about AD 560.

and this imposing volume, originally published in a Hebrew edition, contains much of direct scientific interest. No country with a terrain as varied as that of Palestine and no people with an ancestry and history as rich as that of Israel can fail to command the attention at least of geologists, archaeologists and sociologists, but botanists and zoologists too will find a fund of information far exceeding that available in a traditional Bible atlas. There is a map of the Mediterranean breeding areas and migration routes of the locust; another giving the distribution of plants on the verge of extinction—but no comment on the presence of lions in the Sephelah in the days of Samson.

For the ethnologist, Israel contains material for a thousand PhD theses, but among a welter of data on the settlement of the land during the past century and comparative demographic figures for the various population groups, only scant information is apparently available on the countries of origin of Jewish immigrants: there is simply a breakdown into two groups—those born in Europe, America or Australia, and those from Asia or Africa. On the other hand, the documentation of world Jewry is extensive and one is confronted with the fact that there are many Jews (2·5 million) in the Soviet Union as in Israel, and twice this number in the United States. (The world total is listed as 13·6 million for 1967.)

Having scanned through the remaining sections on local agriculture, industry, social services, culture and so on, most readers, and especially those interested in the history and religious significance of Israel, will want to go back to the collection of old maps—the Medeba map, for example, in a magnificent two-page spread. Archaeology is given meagre coverage, but there are good historical maps from the times of the patriarchs up to the six-day war. (The standard map used throughout the book has the new *de facto* borders of June 1967.)

At 52 guineas, the book might have been graced with a rather more luxurious binding. Yet essentially this is not a prestige or presentation work, and those who will buy it will be readers likely to press it into hard service.

J. H. MORRIS

STUDIES OF ORGANIZATIONS

Organizational Analysis

A Sociological View. By Charles Perrow. (Behavioural Science in Industry Series.) Pp. xiii+192. (Tavistock: London, August 1970.) 30*s*.

THIS book contains one basic idea about the study of organizations, many interesting case studies and even more argumentative and, in my view, superficial statements about the division of labour in the social sciences.

The basic idea is good, simple and constructive: "organizations differ in their tasks, and thus in the way they are run" (p. 49); "once this is realized, it becomes possible selectively to utilize the many techniques offered for solving organizational problems" (p. 91). In elaboration of this apparent truism Professor Perrow suggests a typology of organizations based on their technology and predicts organizational trouble if there exists a mismatch between technology and structure on the one hand, and control mechanisms or personnel policy on the other. In the development of these ideas the author presents a spirited defence of bureaucracy once technological problems are solved, for "no alternative way has been found to cope with the problem of organizing large numbers of people to produce goods and services efficiently" (p. 90).

This basic idea is, of course, not new and has been applied in this country by the Tavistock group in what they call socio-technical system analysis (which receives a somewhat condescending acknowledgment) and by Joan Woodward's studies which are fully and adequately reported. Still, a good idea gains from repetition and elaboration, particularly when presented in a readable, if somewhat breezy, style, as in the case here.

The book's most distinctive flavour stems from the skilful use of case studies when discussing the environmental context within which organizations function and their diverse organizational goals. Some of the material comes from *Fortune* magazine which publishes regularly profiles of business organizations, but non-profit organizations are also included (hospitals, charities, and the like) to support the interesting conclusion that business apparently suspends competition by legal and extra-legal means more often than one would expect, whereas non-profit organizations engage in more competition than a naïve observer might anticipate.

The book is marred by a sociological imperialism—structure is "in", psychology is "out"—which cannot, of course, be maintained consistently. Not only does the foreword by Professor Vroom advocate an interdisciplinary approach, whereas the author's first paragraph claims the supremacy of sociology, the author himself is forced to inconsistencies, particularly in the interpretation of case studies where individual attitude and behaviour seem to count for more than his general stance would permit. The resistance to unorthodox labour-saving devices—Skinner pigeons as quality inspectors of pills—cannot be understood in structural terms, and he does not even try to do so. Whether the study of industrial organizations should begin or end with the study of the behaviour and attitudes to work of individuals is a debatable point; to exclude it from investigation is surely not possible.

MARIE JAHODA

STRESSES OF DAILY LIFE

Environment and Human Efficiency

By E. C. Poulton. (A Monograph in the Bannerstone Division of American Lectures in Living Chemistry.) Pp. xxi+328. (Thomas: Springfield, Illinois, April 1970.) $15.50.

THE purpose of this book is to summarize the knowledge that has emerged from experiments on human performance as affected by particular stressors. Each stressor is given only about ten pages so there is space to cover a large range including isolation, sleep disturbance, heat, cold, compression, vibration, noise, radiation and drugs.

The treatment is intended to be clear and unequivocal; each chapter begins with a summary and ends with some recipes on how to predict, reduce or avoid the effects noticed. Unfortunately, the state of the art is such that being unequivocal about human behaviour usually means being trite. For example, "radiant heat can produce burns. So also can contact with hot material" (p. 143), "decompression increases with height"

(p. 153), "vibration interferes with accurate vision" (p. 216), "glare makes seeing more difficult" (p. 246), "people who are not addicted to smoking would be well advised not to start" (p. 277). Some of these deceptively simple statements are probably not true: for example, "constant vigilance is required in driving along crowded highways" (p. 68), "a cart vibrates when it is pushed over rough ground, the faster the cart goes the greater the amplitude of the vibration" (p. 209), "drugs can be classified as stimulants or depressants according to the effect which they have upon the brain" (p. 265). It is only fair to add that many of these findings which now seem obvious do so only with the benefit of hindsight; for example, in studies of motion sickness it is important to control or record head motion, the importance of directional lighting to facilitate fault identification, stimulants may increase efficiency at dull work but might be dangerous in case of emergencies which lead to over-arousal and errors.

The book illustrates well the assets and liabilities of the school of human performance experimental psychologists which has flourished since the Second World War. Dr Poulton has been a member of the Medical Research Council's Applied Psychology Research Unit at Cambridge for more than twenty years. He is the complete exponent of this kind of psychology. His chapters in the first part on technical problems of experimentation are a model of erudition; he quotes dozens of experiments in the second part and in each case he carefully describes what the results were and mentions the limitation of the particular experimental design, number of subjects and so on. There is a tendency to be parochial. It is claimed in the introduction that the two hundred and fifty references represent only the most relevant ten per cent of possible references. In fact, if four or more references from one author are listed, that author is likely to be a fellow member of the Cambridge unit. The school adheres to the philosophy that the understanding of behaviour is confused by too many people having too many opinions based on inadequate evidence. Therefore, the thing to do is to stick to the evidence, trust only the controlled laboratory experiment and build up a body of knowledge by carrying out experiments suggested by the findings of earlier experiments. This is fine, providing it is not assumed that what emerges is a comprehensive picture of human behaviour. Confine presentation of information to that which has no history, no context and no real consequences, confine also the possibility of outputs to a small range of simple responses which are easily recorded, confine the human subjects to servicemen and students acting on simple instructions and after twenty years what you get is a picture of human behaviour which is totally unrecognizable to anybody not playing this particular psychological game.

In part one, two models of human performance are described. The first one sees the human being as an information processor with inputs, outputs, selectivity, long and short term stores and, in the middle, a slow "computer" of limited capacity. It is at least recognized that this is inadequate and so we have a second model entirely disconnected from the first, which centres on the concept of arousal. There are discrepancies in measurement, but arousal is seen as a unidimensional factor and

FELL AND DALE

These craters are not on the Moon but are corrie basins in the heart of the English Lake District. The Coniston fells are shown in the foreground and the Langdale area is beyond. This photograph, taken by C. H. Wood (Bradford) Ltd, is one of several excellent plates in a new addition to the series "The Regions of Britain"—*The Lake District* by Roy Millward and Adrian Robinson (Eyre and Spottiswoode: London, October 1970, 75s). *The Lake District* follows the format of the earlier *The Pennine Dales* and *The Upper Thames* in introducing the reader to the geology, scenery, prehistory, and the history up to modern times of this small region, but there is, as well, enough detail for the specialist to enjoy reading sections of the book. Like its predecessors in the series, *The Lake District* is very readable and the text is helped along with 40 plates and many useful text figures and maps.

so, for the present, we have performance arousal, physiological arousal, subjective arousal and finally "actual" arousal. Individual differences are a tiresome source of error; in discussing experimental design it is stated that ". . . there is a certain amount of variability between people which cannot be removed" (p. 44).

Given these self imposed limitations of approach, however, Poulton has done his job. Anybody interested in brief summaries of what controlled experiments have revealed about any of twenty-odd separate human stressors will find it in his book. The last chapter describes what little is known about pairs of stressors acting together. What happens in the normal human condition of different individuals pursuing different goals with different drives under a range of stressors is still anybody's guess.

W. T. SINGLETON

KNOTTY PROBLEMS

Knots

By R. D. Laing. (World of Man: a Library of Theory and Research in the Human Sciences.) Pp. 90. (Tavistock: London, September 1970.) 30*s*.

IT is strange to find what appears at first sight to be a collection of poems among a series entitled "World of Man: A Library of Theory and Research in the Human Sciences", but then R. D. Laing is noted for his pursuit of novel forms of inquiry into the human psyche. The poems displayed in this book are for the most part descriptions of the bizarreries and intricacies of attitude that are commonly expressed in the course of human interaction. The result is a series of snapshots which capture, in the precise form of bold type on white paper, the strangled, semiconscious, less-than-verbalized arguments we trap ourselves in.

The poems are word games of occasionally vital personal importance, during which statement and answer are related by a thread of confused yet justifiable personal logic.

> Mother loves me
> because she is good
> I am bad, to think she is bad
> therefore if I am good
> she is good
> and loves me
> because I am good
> to know she is good.
>
> I am bad
> to doubt she punishes me for doubting
> she loves me by punishing me
> for doubting she loves me,

and so on.

We all experience the urgent need to express highly complex feelings and situations when relating to another person. This need is often inadequately fulfilled, the words becoming bogged down in an impasse, a full circle, a knot. How often this has turned a conversation into an escalating conflict. We recognize the familiar truth that the representations possess with a sense of uncomfortable amusement:

> She is devoured, by him being devoured by
> her devouring desire to be devoured
> He is devoured by her being devoured
> by him not devouring her.

The episodes recreated here are like a picture of a hand finishing the outlines of another hand which is finishing the outlines of the first. Laing's drawings have this type of paradoxicality, but they are not *trompe l'oeil* fantasies but reproductions of actual situations. What is impossible in physical space is not only possible but common fare in intrapersonal space. We constantly find ourselves portraying another's act of portraying us. It is in terms of our notions of the other's portrait of us that we have to constitute our own self-portrait. But the other's portrait of us is itself based on the other's estimate of our own self-portrait, and so on. Thus, in order to provide ourselves with a self-image and an other-image which will enable us to determine the way we are going to act towards them, we have to go through operations of enormous logical complexity. It is not surprising that sometimes the fuses blow and we end up enmeshed in self-deception and circularity. This idea, explored in *The Politics of Experience*, is displayed in *Knots* in a more sophisticated form, stimulating the reader to an extensive logical and metaphorical introspection.

For this reason the book is entertaining to read, and in proportion as the passages impress upon us their familiarity, it is revealing. There are places, however where the mode of presentation and the presenter seem to be more in focus than what is being presented. But then it is very difficult for somebody else to provide us with our mental belongings without putting their finger prints all over them. It may be philistine to wonder whether certain parts of the book are conceived with slightly more levity than would seem consistent with the book's apparent general aim, but again, some will find that heartening.

STEVE FULDER

SOCIOLOGY OF CRIME

Crime and Its Treatment

By John Barron Mays. (Aspects of Modern Sociology The Social Structure of Modern Britain.) Pp. 164. (Longman: London, October 1970.) 30*s* boards; 15*s* paper.

THIS elementary but well informed text summarizes current criminological ideas in a concise and stimulating manner that should have a wide appeal to students. The realistic emphasis on the factual content of criminological data is helpful. It is pointed out very early on that ninety per cent of criminal convictions are for offences against property, which are predominantly committed by working class males, many of them schoolboys. The complementary quality of sociological and psychological theories is also clearly demonstrated. On the one hand, property crime may be said to be part and parcel of the conventional way of life in the economically poor urban neighbourhoods. On the other hand, whether any particular child in the working-class ghetto becomes an official delinquent is largely decided by the quality of his home life and upbringing.

Most of the adult habitual offenders known to the prison authorities are men whose personality deficiencies render them vulnerable to temptation. They are exploited as "jackals of the trade" by the small but troublesome minority of more competent, organized, professional criminals who are responsible for an increasing number of well planned and profitable coups. These organized criminals pose a threat to the welfare of the community and present a problem altogether different from that of the rank and file of more or less pathetic cases that make up the clientele of social workers and prison administrators.

The relative immunity of the affluent classes from criminal convictions is discussed sceptically. Embezzling tax evasion and business fraud, when found out, are often dealt with as if they were not really crimes at all. The offenders themselves and their associates would never put themselves in the same category as the common burglar although the amounts taken may be incomparably greater.

Professor Mays brings an experienced and humane approach to bear on these emotional topics. In the section on penal treatments he discusses frankly the absence of convincing evidence of the effectiveness of any particular panacea. At the same time he wisely points out "What we do does not seem to make very much difference either way, but to do nothing is to resign ourselves to despair and

possibly to cynicism" (p. 123). He also makes the point, which may seem obvious but cannot be too often repeated, that it is during the transition from institution to community living that the ex-inmate stands in greatest need of help and guidance. He regrets that the new parole system, by selecting the deserving cases, may serve to push to the end of the line the homeless and helpless who most need assistance.

This short, forthright book, which draws on the best of academic thinking and research, has the effect, possibly not intended, of revealing the extent to which criminological ideas reflect statistical trends and generalizations about offenders which conceal the complexity and variety of the problems involved. On almost every fundamental issue, from the true distribution of criminal behaviour in the community to the question of what treatment is best suited to different types of offender, firm answers will not be forthcoming without further research. The kinds of inquiry most needed may be difficult and embarrassing, but without much more and bolder research political decisions will continue to be made on the basis of prejudice rather than knowledge.

D. J. WEST

Physical Sciences

ASTRONOMY 1850-1939

The Royal Institution Library of Science
Astronomy

Edited by Sir Bernard Lovell. (Being the Friday Evening Discourses in Physical Sciences held at the Royal Institution, 1851–1939.) Vol. 1: Pp. xvi + 416. Vol. 2: Pp. x + 397. (Elsevier: Barking and Amsterdam, 1970.) 200*s* the set.

A SPECTATOR of the London scientific scene during the 1870s remarked on the unique character of the Royal Institution Friday evening discourses. They were, he said, "a wonderful combination of science and society, of physics and fashion"; yet, at the same time, they were, "of sufficiently high class to please all but a purely scientific audience". These two volumes, reprinting Royal Institution lectures on astronomy, confirm the truth of his appreciation. Most of the great names in British astronomy between 1851 and 1939 appear here, together with some, well enough known in their own day, who are either now generally forgotten or, at least, are not remembered as being interested in astronomy.

The period covered by these volumes is, of course, determined by the Royal Institution's history, but it also happens to span very nicely that most important astronomical event—the origin of astrophysics as a fully

The Board of Visitors of the Royal Observatory, Greenwich, photographed at the Observatory on Visitation Day, June 5, 1897. Among the party are several astronomers who delivered discourses at the Royal Institution. From left to right : R. B. Clifton (Royal Astronomical Society), A. W. Rücker (Royal Society), H. H. Turner (Savilian Professor of Astronomy, Oxford), Sir George Stokes (Royal Society), W. D. Barber (Secretary), Lord Rayleigh (Royal Society), J. W. L. Glaisher (Royal Astronomical Society), G. H. Darwin (Plumian Professor of Astronomy, Cambridge), Earl of Rosse (Royal Society), A. A. Common (Royal Astronomical Society), W. Huggins (Royal Astronomical Society), and F. W. Dyson (Chief Assistant, Royal Observatory). (Photo: Royal Greenwich Observatory.)

fledged science. At the beginning of this period, astrophysics was almost non-existent. Thus the first lecture printed here is Airy's discourse on the forthcoming solar eclipse of 1851. This was the first to be observed in detail by astronomers, and it led to the long sequence of nineteenth century eclipse expeditions, which raised so many questions concerning the nature of the solar atmosphere —and answered a few of them. At the other end of the time sequence, the last discourse is by another Astronomer Royal, Spencer Jones, on the projected 200-inch telescope: the instrument which better than any other symbolizes modern astrophysics.

These volumes allow us to follow the often complicated development of astrophysical ideas during the past century. Many of the conceptual changes have been remarkable: none more so than in the timescale allotted to the universe. In 1887, Sir William Thomson explained to his audience: "Five or ten million years ago he (the Sun) may have been about double his present diameter and an eighth of his present mean density . . . but we cannot, with any probability of argument or speculation, go on continuously much beyond that". Just about fifty years later Sir James Jeans told his audience: ". . . we find that 5 million million years ago, the Sun was probably many times as massive as now and many times as bright". The current value for the age of the Sun is more or less the geometric mean of these two estimates.

The timescale has been a central question in astronomy throughout the nineteenth and twentieth centuries; other areas, less subject to intense scrutiny, have experienced fluctuations in fashion. Dewar's experiments on the gaseous constituents of meteorites—reported by him to the Royal Institution in 1886—were for many years the best of their kind: it is only in the past two decades that there has been a renewed interest in this type of investigation. Similarly, there have been varying fashions in ideas: Balfour Stewart's discourse (1867) on the Sun as a variable star refers to the part played by the planets in influencing the behaviour of sunspots. This suggestion was revived, albeit in modified form, just a century later, in the 1960s. In view of the current British plans for the development of infrared astronomy, Piazzi Smyth's preliminary site-testing in Teneriffe (reported to the Royal Institution in 1858) may also come in useful after a lapse of a century. Smyth, happily, was enthusiastic about the site. "Then how truly serene and quiet, and transparent, too, was the air above our 8,900 foot elevation; for, on erecting our telescopes, not only was each star, high or low, seen with an exquisite little disc and nearly perfect rings, but the space-penetrating power was extended with the same instrument and same eye from the 10th magnitude at the sea level, to the 14th."

These two volumes are fascinating, if rather expensive, and can be recommended both for serious and for bedtime reading. Misprints in the body of the text cannot, of course, be blamed on the publishers, because these are photographic reprints. But the blurb describes the editor, Sir Bernard Lovell, as having been president of the Royal Astronomical Society in 1964; he is in fact the current president.

A. J. MEADOWS

RADIO ASTROPHYSICS

Radio Astrophysics

Nonthermal Processes in Galactic and Extragalactic Sources. By A. G. Pacholczyk. (Series of Books in Astronomy and Astrophysics.) Pp. xxi + 269. (Freeman: San Francisco and Folkestone, September 1970.) 122*s*.

A LARGE body of observational data is available for the 10,000 or so radio sources now known. These include, among other parameters, measures of source spectra, energy flux, size and polarization. Before this material can be interpreted in terms of the physical conditions within the sources, it is necessary to have a well understood theory of the emission mechanism. Indeed, the synchrotron mechanism in which radiation is generated by relativistic electrons gyrating in a magnetic field is believed to be an adequate theory for the majority, if not all, of the galactic and extragalactic continuum radio sources.

Dr Pacholczyk has written a useful text on the emission processes in radio sources. He has concentrated on the synchrotron process for which he has provided a thorough introduction. The effects on the emission by the surrounding plasma are included as are the effects of electron scattering on the emitted synchrotron radiation. A well chosen bibliography is included at the end of each chapter.

A new range of non-thermal processes have recently been recognized in spectral line sources. The most studied of these are the regions of anomalous emission from OH and H_2O molecules in interstellar space. Brightness temperatures of up to 10^{13} K have been measured which are enormously in excess of the kinetic temperatures which exist in these regions and are interpreted as originating in maser action where a weak background signal is amplified in the cloud of interstellar molecules to these high intensities. Line-narrowing, temporal variability and a high degree of circular polarization are trade marks of this type of emission.

It is probably a sign of the rate of advance technically and the associated rate of new discoveries in radio-astronomy that this subject is scarcely touched on in Pacholczyk's treatment. A major branch of non-thermal radio emission mechanisms has been deliberately excluded from this work, namely, the various radio emission mechanisms known to operate in the atmosphere of the Sun. The reason for this latter omission in not so clear, because these mechanisms provide excellent examples of emission mechanisms other than the synchrotron process.

In all, I find this a welcome book bridging the gap between the extensive theoretical treatments and the wide range of observational data. As an aside, it is interesting to find Pacholczyk, a theoretical astrophysicist, falling prey to the observational astronomers' and space-scientists' nightmare—confusing the senses of polarization which an antenna receives and transmits. An antenna receives and transmits the same sense of circular polarization as is adequately demonstrated in Kraus's *Radioastronomy*.

R. D. DAVIES

THE FACE OF THE MOON

Geology of the Moon

A Stratigraphic View. By Thomas A. Mutch. Pp. 324. (Princeton University: Princeton, New Jersey; Oxford University: London, August 1970.) 165*s*.

PROFESSOR MUTCH, a stratigrapher who has worked at the US Geological Survey's Center of Astrogeology at Flagstaff, is well qualified to discuss lunar stratigraphy. His book is not, however, as specialized as the subtitle might indicate. The author appeals to all the important aspects of lunar geology, albeit on a superficial level. The text is relatively free from prejudice and, together with the general lack of great depth of treatment, combines with the well-chosen illustrations to provide an excellent students' introduction to the geology of the Moon.

Two introductory chapters on aspects of history of the subject and the Moon's orbit and figure are brief and more adequate treatments will be found elsewhere. The third introductory chapter deals, again briefly, with photographic documentation of the Moon and the results drawn from some of the physical methods (such as optical and thermal) used to examine the lunar surface. Key charts identify the locations of the Lunar Orbiters' photographic coverage (but neither cardinal points nor coordinates are

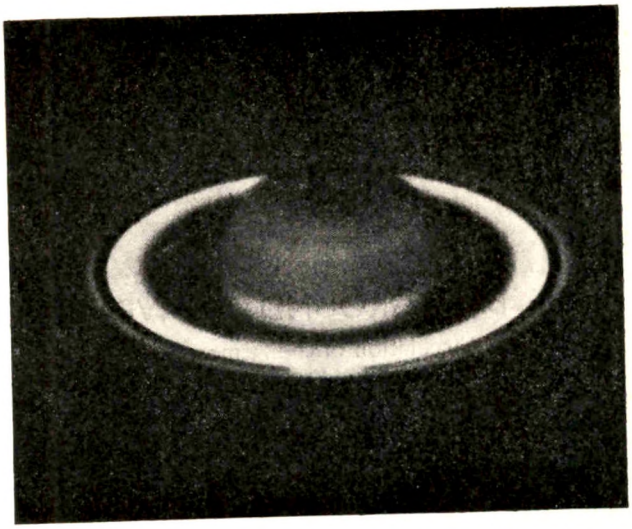
given on the full Moon charts). It is useful to be reminded how the Orbiter photographic strips were assembled from scans of the 70 mm film carried aboard the spacecraft.

Lunar photographs are used liberally—and are among the best ever taken. They are pleasingly reproduced, with a matt finish; but one could wish for better because many of them tend to be rather "muddy".

With the onset of lunar mapping by the US Geological Survey, several years ago, lunar stratigraphy emerged as an interpretative tool of central importance in understanding the history of the Moon's surface. It is by no means the only effective means of access to an understanding of lunar geology, but it is one of the essential paths that can be investigated in a reasonably short time only by a team of lunar workers larger than is commonly encountered in, say, the universities. Dr E. Shoemaker led this mapping programme and directed much attention to a study of Mare Imbrium and the characteristic facies (some would say "deposits") that are associated with it and are found over a large part of the Moon's surface. Mutch expounds on the Imbrium stratigraphy and proceeds to describe the stratigraphies of other lunar maria and craters, and then of volcanic flows and deposits on both Earth and Moon. He avoids one important problem concerned with the flow in Mare Imbrium (Fig. VIII–21), in which the number density of craters is appreciably higher on the most recent flow than on stratigraphically older units (one might expect the converse) by stating, in the caption, "Crater densities on both sides of the flow are similar . . .".

Interpretation of reported facts is minimal and is coloured by prevailing US Geological Survey views. Most of the viewpoints expressed will find general support; some of these ideas may change, but Mutch does not stick his neck out, and one of the values of his book is that it will remain a useful reference work. The chapter on highland stratigraphy, and the crisp impressions of lunar rocks in the photographs taken during and following the Apollo XI mission, highlight the terminal parts of the book: it should be read by students of the Moon.

G. FIELDER



MAN AND THE SOLAR SYSTEM

The Atlas of the Universe

By Patrick Moore. Pp. 272. (Mitchell Beazley with George Philip: London, September 1970.) 215*s*.

THIS is definitely a book for the coffee table rather than for the professional library, but the many excellent colour pictures of the Earth from various NASA surveys are alone worth the cost of the volume, and may perhaps ensure that it will be found on the coffee tables of professional institutions as well as those of the private individual. The rest of the book leaves much to be desired in view of its all-embracing title. It is not an atlas of the universe (let alone the definitive work suggested by the use of the definite article), any more than a book of the same length could claim to be a history of the world; it is only on page 188 that discussion of the stars is introduced (along with more excellent illustrations), and less than 10 per cent of the volume is devoted to discussing external galaxies.

It is unfortunate that the author has overreached himself in this way, because his product is much more impressive when considered as an atlas of the Solar System. The text adds nothing to the information available in other books with less extravagant titles, but the illustrations (both photographic and diagrammatic) are so profuse and of such a high standard that they are informative in themselves, and may encourage some readers to delve further into a study of astronomy and space science. Because of this, the atlas seems particularly suitable for schools.

Saturn's rings, photographed by the Lowell Observatory, Flagstaff, Arizona (from *The Atlas of the Universe*).

Although I cannot agree with the packaging of the book, its contents are of undoubted worth, and would be even more commendable presented in the context of man's exploration of the Solar System, from which its inspiration and much of its content are clearly drawn. The apparently belated recognition of this by the producers of the book makes the discrepancy between package and contents still more irritating—if the epilogue by NASA's Dr Thomas Paine had been used as a prologue, and the title of the book suitably altered, it would have been wholly admirable.

JOHN GRIBBIN

IONOSPHERIC PHYSICS

Propagation of ELF and VLF Waves near the Earth

By Yakov L. Al'pert and Dora S. Fligel'. Translated from the Russian by James S. Wood. Translation edited by James R. Wait. Pp. v+171. (Consultants Bureau: New York and London, 1970.) $22.50.

THIS book represents a concise summary of several of the theoretical problems encountered in the study of waves in the frequency range $0{\cdot}001 < f < 30$ kHz propagating in a bounded medium. The authors, in their introduction, suggest that they wish to give an insight on this branch of radiophysics to the inexperienced reader. In this they have been unsuccessful because many of the problems discussed are presented assuming that the reader has a strong background. As a reference text for the expert, however, this book contains a wealth of information pertaining to certain boundary value problems encountered in the propagation of electromagnetic waves in the ionosphere. In particular the authors give an excellent account of the evaluation of the roots of the pole equation, which does much to enhance the readability of the mathematical development. To acquire an adequate background before attacking this book, the reader should first study Al'pert's original book *Radio Wave Propagation and the Ionosphere* of which this new book is a natural offshoot. This would give the reader a chance to familiarize himself with Al'pert's style and notation, as well as giving him a feeling for the transition in thinking from the pre-satellite days of Al'pert's first book to the present time when satellites are capable of making *in situ* measurements of the wave phenomena which Al'pert studies theoretically. The reader benefits from a large number of comments by the editor (J. R. Wait). As the editor

is himself an expert in electromagnetic boundary value problems, this comes as a welcome addition to the text.

In summary, this book cannot be considered as a useful text for the inexperienced reader, but it stands as an excellent reference work for the expert wishing a concise summary of certain of the boundary value problems encountered in ionospheric physics.

GORDON ROSTOKER

THE BACKGROUND TO WEATHER

The Global Circulation of the Atmosphere

Edited by G. A. Corby. Pp. 257. (Royal Meteorological Society: London, 1970.) n.p.

FOLLOWING a well tried pattern for scientific symposia, the joint conference of August 1969 between the Royal Meteorological Society and the American Meteorological Society consisted of a number of invited review papers by leading workers, together with a comparatively large number of additional contributions submitted and presented by their authors. The pattern usually ensures successful sessions, but publication then presents a problem, because the invited papers are rarely "original" and the submitted papers are inevitably of uneven quality.

The decision, in this case, to publish only the principal invited survey papers in a conference report, leaving the remaining thirty-five papers to take their chance in the scientific journals, may be regretted by many participants, but certainly provides a handy volume of permanent value. It must surely stand as a 1969 landmark in the progress of understanding of the circulation of the Earth's atmosphere on the global scale.

It is a remarkable fact that, in spite of all the complications and variability of weather, the climate of the planet Earth has a rather simple background structure—equatorial rains, subtropical deserts and so forth—evidently related with prevailing wind systems, the doldrums, the trades, the middle latitude westerlies, the monsoons. The description and explanation of this atmospheric structure in four dimensions, the exploration and the theory of world climate, have exercised meteorologists at all times, but not until very recent years could we claim to have the makings of a dynamical theory. By expressing the basic laws of fluid mechanics in standard forms and by making gross but plausible assumptions to overcome the barriers of ignorance on boundary conditions and on the statistical effects of small scale phenomena, it has, in the past decade, become possible with high speed computers to calculate mean world circulations which are recognizably realistic. This success encourages the belief that with sufficient application almost any degree of verisimilitude is attainable, and the large cooperative world programmes of World Weather Watch (WWW), and Global Atmospheric Research Programme (GARP), are an earnest of faith in progress.

The first paper is by E. N. Lorenz and nobody is more competent than he to describe "The Nature of the Global Circulation", or to recognize the difficulties which, unsuspected by some optimists, may lie ahead. His recent (1967) monograph on this subject, published by the World Meteorological Organization (WMO), is a masterpiece. Then there is a paper by J. Smagorinsky, also from the United States, who has done perhaps more than any other person in the world to advance numerical simulation of large scale atmospheric circulations. Other authors are P. A. Sheppard, D. H. Johnson, C. W. Newton, R. J. Murgatroyd, R. Hide, V. E. Suomi and B. R. Bolin, an impressive list of experts presenting articles on the boundary layer, the role of the tropics, of extratropical disturbances, on the stratosphere, on laboratory experiments, satellite techniques and GARP. In addition to this a group of four from the Massachusetts Institute of Technology, R. E. Newell, D. G. Vincent, T. G. Dopplick and D. Ferruzza, assisted by J. W. Kidson from New Zealand, provide a remarkable 50-page summary on the global energy balance—a work of reference in itself.

A practical benefit of these studies could ultimately be found in scientifically objective long range weather forecasts based on a sound knowledge of the global circulation and the associated climatic factors, first of their average state, then of their variability, from year to year. An alternative approach, an extension of short range forecasting by mathematical modelling, is to predict the variability with time as far ahead as possible as an initial-value problem, using data for the whole planet. The mean global circulation and world climate are then the averages of the predicted variable fields, and one check on the prediction model is provided by the realism of the outcome. Thus theoreticians will ask whether the model gives a true picture of energy fluxes, of momentum fluxes, of vorticity balance, of moisture balance and so forth. This conference introduces all these thoughts as well as more practical considerations of observational needs for the continuous surveillance of the global atmosphere. The impression is gained of highly complicated science and costly operations which must continue for many years before the goal of long range forecasts is likely to be reached by this arduous path. But given the present awareness of the problems and their formulation in convincing scientific terms, continuing efforts must be supported. Another Anglo-American conference in ten years' time will have much progress to report if the pace of the last decade is no more than maintained.

R. C. SUTCLIFFE

STUDENT GEOPHYSICS

Global Geophysics

By R. H. Tucker, A. H. Cook, H. M. Iyer and F. D. Stacey. Pp. vii+199. (English Universities: London, September 1970.) 45*s*.

IT took Chapman and Bartels more than a decade to write their famous definitive work on geomagnetism. If that sounds like the result of the so-called literature explosion, it is perhaps pertinent to recall that the treatise in question was first published in 1940, well before the post-war expansion in science. The most recent "standard" work on geomagnetism was the product of multiple authorship; and it does not need a prophet to foretell that no single author, or pair of authors, will ever again write a book on geomagnetism which has any pretensions to completeness. And in so far as geomagnetism is but a small part of geophysics, it is obvious that a single-author treatise on the latter is completely out of the question.

Multiple authorship of advanced texts is thus dictated by the exigencies of modern science and the shortness of life. The case for multiple authorship of a short, introductory book on geophysics is less obvious; but if it exists, it should be made if only because there is a clear tendency nowadays to use multiple authorship where it is not dictated by the subject simply to produce "instant" commercial properties at the expense of science and the scientific budget. The valid case can, of course, only rest on the advantages of combining the expertise and authority of writers in diverse fields. I am able to report that this book is one happy proof of this validity.

The book comprises four chapters. Mr R. H. Tucker first sets the scene for the later chapters on the solid Earth by considering the Earth as a body in space—the part it plays in the solar system and the consequences of its intrinsic rotation. Professor A. H. Cook then follows in a somewhat longer section on the Earth as a rotating body with a gravitational field. This is the least successful

chapter purely in the sense that mathematics is unavoidable in what is intended as an essentially non-mathematical text. Next, Dr H. M. Iyer deals with seismology and earthquakes. This is a remarkable chapter by any standards, from the points of view of content, style, level and organization. Dr Iyer has succeeded admirably in writing an introduction to the principles and results of seismology without becoming hopelessly mathematical and has, at the same time, managed to include recent topics such as earthquake prediction, man-made earthquakes and nuclear seismology. Finally, Dr F. D. Stacey discusses geomagnetism, palaeomagnetism, the magnetosphere and the Earth's radiation belts.

Although this volume is limited in scope, it is nevertheless the best introduction to geophysics I have yet seen, combining, as it does, basic ideas with exciting recent developments in eminently readable form. Its merits are such that it has already been recommended as collateral reading for first year science students at the Open University.

PETER J. SMITH

SALTS IN SEDIMENTS

Principles of Lithogenesis

Translated by J. Paul Fitzsimmons. Edited by S. I. Tomkeieff and J. E. Hemingway. Vol. 3. By N. M. Strakhov. Pp. xii+577. (Oliver and Boyd: Edinburgh; Plenum: New York, August 1970.) 210*s*.

THE third volume of Academician N. M. Strakhov's monumental work *Principles of Lithogenesis* was published in Moscow in 1962. Its appearance in English translation completes the wide introduction of this important study to the scientific community in the West.

This volume is about the way in which metallic salts become concentrated in sedimentary deposits by the operation of processes essentially contemporaneous with or directly responsible for sedimentation. The term halogensis is used to cover the genesis of such concentrates, whether Strakhov is concerned with the production of sedimentary ores of copper, lead and zinc, or the formation of the more familiar potash and halite deposits. The discussion of these processes and their expression through time is divided between the three parts of the volume.

The first part deals with the earliest stages of halogensis, as expressed at the present time and in the past. There is a long account of sedimentary ores of copper, zinc and lead, and some treatment of the way in which calcium and magnesium carbonates become concentrated under different geological circumstances, from shallow seas to river floodplains.

The second part of the book describes the present-day occurrence of salts and the physico-chemical processes that are responsible. The deposits in the well known Kara-Bogaz Gulf are described on the basis of the latest Russian studies, but many other salt lakes, chiefly in Asia, are given detailed description and analysis.

In the third and longest part of the book, Strakhov outlines the geological occurrence and facies structure of ancient deposits of salts. The deposits are described in terms of a broad environmental classification: continental, lagoonal, isolated gulfs, and epicontinental seas. The concluding chapter summarizes the geological occurrence of salt deposits and discusses the development of halogensis throughout Earth history.

This book is an invaluable source of detailed information and ideas about salts deposits in Russia and Asia generally. Its publication opens up for Western geologists an important new world of data and ideas. The production is, on the whole, very good, with line drawings that are a substantial improvement on those in the previous two volumes. The omission of an index is, however, a serious defect.

J. R. L. ALLEN

STATISTICS IN GEOLOGY

Statistical Analysis of Geological Data

By George S. Koch, jun., and Richard F. Link. Pp. xi+375. (Wiley: New York and London, September 1970.) 125*s*.

A NUMBER of books dealing with statistics in geology have been published in the past eight years. Although covering much the same ground as standard statistics texts, they seem in general to have been well received by geologists. Examples are set in a geological context, methods are evaluated from a geological standpoint, and stress is placed on procedures, such as trend-surface analysis, which are of particular significance in Earth science. Although many of the earlier books have been biased towards stratigraphy, sedimentology or petroleum geology, this new volume by Koch and Link is oriented towards the mining geologist.

Although this is not indicated on the title pages, this book is intended as the first of two volumes, and regression, correlation and multivariate methods are not included. The longest section of the volume deals with frequency distributions and population parameters, confidence intervals, analysis of variance and transformations. A subsequent section considers sources of variability and problems of sampling, largely in a petrological and geochemical context. Much of the second section could be read without reference to the first. Although there is no extensive bibliography, an adequate number of key references is given.

The book is intended for readers with some geological training but little or no statistical knowledge. One hopes that such readers will not use it as their only source of statistical information. The well-trodden ground of elementary statistical theory is presented in a manner that is inconsistent and is in places difficult to follow. The geological significance of the theory is not always clearly established and examples are frequently either not geological or based on fictitious data. Many, perhaps most, of the statistical methods of importance in geology are not even mentioned. This book on its own is thus of limited value and volume two must be awaited to determine whether it forms part of an integrated whole. There, the authors intend to place geology first, statistics second, and introduce real examples in which the statistical principles described in volume one are put to work, extended and refined as necessary. No publication date for the second volume is mentioned.

T. V. LOUDON

COMPENDIUM OF INEQUALITIES

Analytic Inequalities

By D. S. Mitrinovic in cooperation with P. M. Vasic. (Die Grundlehren der mathematischen Wissenschaften in Einzeldarstellungen mit besonderer Berücksichtigung der Anwendungsgebiete, Band 165.) Pp. xii+400. (Springer-Verlag: Berlin and New York, 1970.) 88 DM; $26.

THE publication in 1934 of the classic *Inequalities* of Hardy, Littlewood and Polya, established the topic as a field of study in its own right, a field since then intensively cultivated. Dr Mitrinovic's compendium will be of great value to the worker who feels sure that a desired inequality must exist if only he could find it. It will also delight those who relish "tricks to show the stretch of human brain" for their elegance or quaintness.

A short introductory chapter deals largely with convex functions, from whose properties many of the fundamental inequalities can be easily inferred. Then there are two principal sections, on general and on particular inequalities. The dichotomy is not entirely clear, but, roughly,

the general inequalities are widely used with applications in a variety of places and the particular inequalities are likely to be of interest purely for their own sakes. In the general section, proofs are usually supplied although they are usually omitted in the other part, but throughout the work the documentation is extremely thorough and the author has ransacked the minor as well as the major mathematical journals for references. He has also been able to include a number of hitherto unpublished results.

To keep the volume within reasonable limits, much has been excluded: deliberately, there is nothing about geometrical and isoperimetrical inequalities, or those connected with number theory or with special functions. Moreover, the author avoids too much overlap with Dieudonné's excellent discussion in his *Calcul Infinitésimal* (1968) and with the 1961 book by Beckenbach and Bellman.

Many items will suggest further research to complete or extend known results. For instance, there is a full account of work on the curious cyclic inequality for positive x's,

$$\frac{x_1}{x_2+x_3}+\frac{x_2}{x_3+x_4}+\ldots+\frac{x_{n-1}}{x_n+x_1}+\frac{x_n}{x_1+x_2}\geq \tfrac{1}{2}n.$$

Mitrinovic has traced the earliest occurrence in the *Educational Times* for 1903 (in the simplest case $n=3$), but remarks that this may not be its first appearance; it would not be surprising to find it somewhere in those Victorian repositories of perverse ingenuity, the Cambridge college and tripos examination papers, though I cannot find it in Wolstenholme or Carr. Interest in it began after the last war; in 1956 it was proved for $n=3,4,5$, whereas Lighthill showed that it is false for $n=20$. In 1958 Rankin proved that it is false for all sufficiently large n, but though much has since been added, there are still nine values of n for which the question remains undecided.

T. A. A. BROADBENT

GEOMETRICAL OPTICS

Geometrical Optics

By Hans-Georg Zimmer. (Applied Physics and Engineering: an International Series, Vol. 9.) Pp. vii+172. (Springer-Verlag: Berlin and New York, 1970.) 34 DM; $9.40.

THIS book is fairly conventional in scope, dealing with gaussian optics and third order aberration theory. The approach used is, however, most unorthodox, in that as far as possible the author avoids discussion of ray paths and the shape of wavefronts. He takes, instead, the standpoint that the function of an optical system is to transfer energy by means of tubes of light, and builds up his analysis in a manner allegedly derived from the principle of energy conservation. In effect he takes as his basic axiom that a quantity called the "linear conductivity" of a light tube is invariant in a perfect imaging process. This is stated (but not proved) to be consistent with energy conservation. The procedure is essentially equivalent to using the Lagrange invariant as the prime means of specifying an optical system. The theory of geometrical optics is then reformulated in terms of the quantity "linear conductivity".

Regrettably this approach serves only to make simple issues seem rather complicated and renders the book most unsuitable for students. Other readers may be put off by a turgid text, a stilted translation and a notation of eccentric obscurity. This is a pity, because the book contains a few interesting original ideas which deserve a better presentation.

M. E. BARNETT

SPIN DENSITY MATRICES

Spins in Chemistry

By R. McWeeny. (Current Chemical Concepts: A Series of Monographs. A Polytechnic Press of the Polytechnical Institute of Brooklyn Book.) Pp. xi+153. (Academic: New York and London, June 1970.) 79*s*.

CHEMICAL physicists with interests in magnetic resonance or valence theory will be familiar with Professor McWeeny's important work on spin distributions and electron density matrices in molecules. This compact and tightly argued series of lectures is particularly welcome, because it links together a variety of useful concepts in theoretical chemistry and brings out the relations between them in new ways. The theme of the book is the theoretical description of electron distributions in molecules which possess unpaired spin or orbital angular momentum, and the origin of the various spin Hamiltonians which are used to describe their energy levels in a magnetic field.

The first lecture on spin and magnetism provides a gentle introduction, and leads naturally into an interesting discussion of the principles which underlie the valence bond theory. The third lecture shows how the Dirac equation leads to magnetic interactions in the molecule, and gives an example of an effective crystal field Hamiltonian with fictitious spin and anisotropic g tensor.

The second half of the book is much more advanced and more formal in its approach. The object is to develop a very general description of electron distributions in terms of spin populations, or one and two-particle distribution matrices, which holds for any kind of molecular wave function with a definite spin and symmetry. The advantage of this approach is that the results are not tied to a particular form of wave function, such as a molecular orbital approximation. A drawback is that one has to learn a lot of difficult notation and master some deep ideas before being able to deal with even simple examples. But McWeeny should easily convince his readers that the effort is worthwhile, because of the very general and powerful methods which he devises. For example, his anisotropic spin-correlation function for triplet states and his spin-orbit coupling density are most elegant concepts. Another point which he brings out well, during a discussion of electron-nuclear hyperfine interactions, is the power of the Wigner–Eckart theorem in reducing the complexity of interactions between different electronic states. The lecture on g tensors and nuclear spin-spin couplings again shows up the virtues of the general methods. This generality should make the book of permanent value to theoretical chemists. There is an interesting appendix on the wave functions of two overlapping molecules with spin, which describes a new and elegant generalization of the Heisenberg spin-coupling idea and the Heiter–London method.

The book is clearly written in a lively style, and those who are willing to work hard should find it very useful.

A. D. MCLACHLAN

SYMMETRIES AND QUARKS

Symmetries and Quark Models

Edited by Ramesh Chand. Pp. xii+406. (Gordon and Breach: New York and London, September 1970.) $33.50; 280*s*.

THE last few years have seen an enormous increase in the number of summer schools, conferences and symposia in many fields, including elementary particle physics. This, combined with the aggressiveness of certain publishers, has led the conference organizers to believe that their meeting is a failure unless proceedings are issued, with a consequent flooding of the market. There is a real

need for such books, possibly roughly produced, but cheap enough for research students and, because of the transient nature of much of the material, brought out quickly. This volume is exceptional in that it is well printed (in East Germany), but otherwise its year delay and its price mean that it is one more book aimed for library consumption.

The style of the contributions is very varied. In the mid-1960s the symmetry game advanced very fast; people speculated and were rewarded. Those days seem to have passed, and the contributions of the people who try to carry on the revolution are not in general very inspiring.

If there were not such strong prejudices against the basis of the Naive Quark Model, the mass of evidence in the review of Dalitz, complemented by that of Mitra, would make the theory universally acceptable. It would be convincing if somebody were to find quarks, but as Jones regretfully concludes, "I suspect that most experimentalists feel that physical quarks are either unobservable or do not exist". The discussion by Lipkin of the quark model as a guide to hadron dynamics is interesting, as are the various comparisons of symmetry predictions with experiment, for example, by Meshkov, Okubo and Overseth. There are also papers on current algebras, partially conserved axial vector current (PCAC), infinite multiplets, and the like.

There is a very thorough article by Yodh on the experimental situation concerning Ξ^* resonances which are predicted by the symmetry schemes. But one has the feeling that more up to date information could be obtained by looking up the latest publication of the Particle Data Group (free of charge). COLIN WILKIN

MAGNETS

Superconductivity and its Applications

By J. E. C. Williams. (Applied Physics Series.) Pp. 213. (Pion: London, 1970.) 60*s* boards; 46*s* paper.

THIS book divides into three parts, unequal in length and quality: first, sixty introductory pages; second, nearly one hundred pages on hard superconductors and their applications; and third, nearly forty pages of other applications.

The middle section is by far the best part. It begins with an introduction to the critical state model. There follows a very full discussion of magnets, including stabilization, considerable detail on materials and examples of specific magnets. Then comes a good chapter on a.c. power devices. The calculations for stabilization, carried out chiefly for the model geometry of a thin plate in a parallel field, are presented in detail. The whole middle section forms a complete and lucid introduction to magnet design, and should be of value to anybody moving into this field.

The introductory part is not so good. It is turgid in places, and it contains several erroneous statements which may not matter for this book, but which are irritating to see. For example, the decrease of the energy gap with temperature has nothing to do with the increase in the number of real phonons present. The vortex core radius is not equal to the free path in the dirty limit.

The miscellaneous applications (magnetometer, Josephson junctions, computer elements and some oddments) are dealt with satisfactorily, except that in my view the Josephson effect is too lightly dismissed. The measurement of e/h (voltage standard) is not even mentioned. The rather promising use of weak links as infrared detectors is not discussed either, although it finds a place in Kimmitt's companion volume on far infrared.

There is a good index, and a bibliography which is thorough for magnets. The paperback version costs nearly as much as the hardback. D. R. TILLEY

NEUTRON SCATTERING

Magnetic Neutron Diffraction

By Yurii A. Izyumov and Ruslan P. Ozerov. Translated from the Russian. Pp. xviii + 598. (Plenum: New York; Heydon: London, June 1970.) 350*s*; $37.50; 150 DM.

THE neutron possesses a magnetic moment and it therefore interacts with the magnetic field produced by unpaired electrons in an atom or ion. The study of the scattering of slow neutrons by magnetic substances is a rich source of information on their magnetic properties. These properties may be divided into two categories, static and dynamic. By the former is meant the magnetic structure or ordering, that is to say, the pattern made by the directions of the magnetic moments (or spins) of successive atoms in the crystal. Originally the only known patterns were the ferromagnetic, in which all the moments point in the same direction, and the antiferromagnetic, in which alternate moments point in opposite directions. Neutron diffraction, however, has elucidated not only these, but several others such as an "umbrella" type in which successive moments lie along the surface of a cone the axis of which remains constant.

Information on these static properties comes from a study of the elastic scattering of slow neutrons. Further valuable information on the dynamics of the moments comes from the inelastic scattering. Here the neutron is scattered by a process in which it causes excitations in the arrangements of the spins. The energy of the latter changes, and this manifests itself as a change in the kinetic energy of the neutron. The knowledge obtained is valuable not only for the magnetic properties themselves, but also for the light it sheds on critical phenomena in general—a poorly understood branch of physics.

This book by Izyumov and Ozerov is a translation of an original version published in Russia in 1966. The title is somewhat misleading in that the word diffraction is usually restricted to elastic scattering, whereas the book also discusses inelastic scattering. The authors discuss the magnetic structures of rare earth metals and their compounds, double metallic oxides, and magnetic alloys. There are chapters on the distribution of magnetic moments, spin dynamics, and the behaviour of ferromagnetic crystals containing impurity atoms. The theory of neutron scattering is developed from first principles, and in spite of the formal nature of much of the analysis, the arguments are presented very clearly. There is much emphasis on the symmetry concepts developed by Shubnikov and his school.

The book will be extremely useful to research workers—both experimental and theoretical—in the field of neutron scattering by magnetic materials, although the price will limit sales. G. L. SQUIRES

INORGANIC RINGS

The Chemistry of Inorganic Ring Systems

By Ionel Haiduc. Part 1: Pp. vi + 1–622. Part 2: Pp. 623–1197. (Wiley (Interscience): London and New York, August 1970.) 500*s* the set.

THE ring symbolizes power, authority, betrothal and marriage, eternity, and perfect form; "in my beginning is my end". Rings have been used in medicine (to ward off the cramp), and poison rings for murder or (as by Hannibal) for suicide. The serpent biting its own tail, an alchemical sign for the unity (or perfect form) of matter, and for circulatory processes, was the image that came to Kekulé when he thought of the ring structure for benzene.

Inorganic rings were made, unwittingly, by Liebig and Wöhler, and by Rose, in 1834 (*cyclo*phosphazenes), and by Gregory in 1835 (*cyclo*tetrathiazene, S_4N_4). But demon-

stration of their ring structures took 60 and 110 years respectively, in spite of the stimulus to find ring systems that followed Kekulé's benzene ring formula in 1865. Many were formulated, and most were wrong. Butlerow in the 1870s and 1880s predicted that rings and polymers should be common in inorganic as well as organic chemistry; but Werner's coordination theory of valency in 1893 tended to discourage the quest for the ring. The *cyclo* tri and tetraphosphates were correctly described in 1875–80, Stokes's *cyclo*phosphazenes in 1895, and siloxanes by Dilthey in 1905. Borazine was discovered by Stock in 1925 and its structure proved in 1931. For *cyclo*tetrathiazene a ring formula was discussed (among others) in 1936, and demonstrated (by electron diffraction) in 1944. Now the rate of advance is exponential.

The study of inorganic rings is rich and rewarding, and Ionel Haiduc's book in two volumes is worthy of its subject. As a Romanian who has worked during the past ten years both in the Soviet Union and in the United States he spans the international literature admirably. Nevertheless, he cuts a clear path through the jungle of proliferating derivatives. Introductory chapters deal with systematic nomenclature, structure and bonding, and ring equilibria. He then covers homocycles and heterocycles (of which 230 are listed in his ring index) of group III to VI elements; and polycycles, and heterocycles containing titanium, or vanadium. A useful chapter describes coordination heterocycles containing non-transition metals and also the recent chemistry of transition–metal heterocycles, which form a link between the metal complexes, and ring compounds of non-metals and semi-metals. A further achievement, of author and publisher, is to add, in proof, literature references up to mid-1969.

I have few criticisms. In view of the author's subject, one may perhaps condone some cyclic logic (under "Hybridization" it is stated that a (cyclic) arrangement, involving only atoms in their characteristic hybridization states, will be preferred to structures involving a non-characteristic hybridization. This is said to explain the instabilities of such groupings as —B=O, >Si=O and the like). The implications of spectroscopic and theoretical work are not usually discussed, nor are mechanistic implications generalized, although the references are well covered. But critical acumen, which is so often lacking in books that contain this amount of information, is evident here, and the organization is good.

It is a pity that the price will prevent chemists from buying their own copy of this very useful book.

JOAN MASON

REACTORS AND RANDOM NOISE

Random Noise Techniques in Nuclear Reactor Systems

By Robert E. Uhrig. (Prepared under the auspices of the US Atomic Energy Commission.) Pp. x+490. (Ronald: New York, 1970.) $20.

ALTHOUGH this book is primarily designed for engineers and scientists interested in applying random noise techniques to nuclear reactor systems, it is not limited to that field. Only three of the twelve chapters deal specifically with nuclear processes. One describes the statistical techniques for dealing with the detection of individual neutrons in a nuclear assembly, one treats this detection process as continuous and examines the analysis of the fluctuations of the detection current, and one is made up of several examples of experimental noise measurements carried out on nuclear reactor systems in recent years, which presents a well balanced and wide ranging selection from the wealth of such work. These chapters require a working knowledge of nuclear reactor theory to be understandable.

Other chapters develop the theory of random noise from elementary probability theory through special probability densities and distributions to correlation and autocorrelation functions, power and cross spectral densities and coherence functions. In these mathematical chapters no attempt is made to be rigorous, the main definitions and results are stated or made plausible and numerous examples and explanatory diagrams are given. There are a number of missing or misplaced indices and suffices which cause momentary confusion in places.

The remaining chapters are concerned with the instrumentation and measurement techniques for the acquisition, transmission, recording and processing of data from random noise experiments, and here the pages are shot through with first-hand knowledge. Practical measurements of correlation functions, spectral densities and impulse-response functions, analog and digital techniques, multiplexing and the use of pseudorandom variables, all these and more receive a clear and concise treatment. These chapters along with the mathematical ones could be equally applied to a wide variety of physical and engineering systems. Herein lies the book's usefulness.

The author has to a large extent succeeded in his aim of making the book self-contained, although to be told after equation (3–1) that "all symbols have the definitions commonly accepted in reactor theory" suggests that perhaps an additional chapter or appendix on basic reactor theory would have made it even more so. Each chapter has a good selection of references, and the index is fully comprehensive and adds much to the overall utility of the book.

DON FIRTH

POLICY IN MATERIALS SCIENCE

Materials Science and Engineering in the United States

Edited by Rustum Roy. (Proceedings of the National Colloquy on the Field of Materials held at the Pennsylvania State University, University Park, Pennsylvania, April 14–16, 1969.) Pp. xiv+177. (Pennsylvania State University: University Park and London, October 1970.) 90*s*.

SOME ten years ago metallurgy and solid state physics married and materials science was born. The way in which this new discipline has developed since then, the role of government, industry and the university, the future trends, are all aspects which formed the basis of the colloquy which is reported in this volume. The substance of the principal addresses given at the colloquy, together with summaries by rapporteurs of the discussions, are included. The contributors are all scientists and engineers who have made important contributions to the non-scientific development of materials science and engineering in the United States.

The colloquy was the first of its kind, which makes the content of this book very special and timely. It is a pity that the title is so specialized, because apart from the obvious significance to those involved in materials research, some of the subject matter is relevant to people engaged in research policy making in all branches of applied sciences, including the life and Earth sciences. The reason for this is not obvious but should be apparent when it is understood that materials science is a classic example of an interdisciplinary subject, which has now emerged as a discipline in its own right. Currently many of the important growing areas of research have factors common with materials science and there are lessons to be learned.

In assessing the development of materials research in the past decade, a significant step was the sponsorship of the Advanced Research Projects Agency Interdisciplinary University Materials Laboratory Program (ARPA-IDL) in 1960. The products of this scheme are discussed

in this volume along with the problems involved. Particular problems of university teaching and research, university–industry–government interaction, and future trends are also discussed.

In the book there is a distinct trend of growing social awareness in all the discussion on future research. Six national civilian goals have been identified by the Co-ordination Committee on Materials Research of the Federal Council for Science and Technology: (1) low cost housing; (2) high speed ground transportation; (3) air pollution control; (4) water pollution control; (5) biomedical materials; and (6) energy generation and transmission. The potential problems of tackling such mission-oriented projects are not obvious and the opinions presented here are extremely perceptive.

There are also accounts of materials research in Britain and France, together with some surveys of university materials programmes in the United States and some information from questionnaires on industrial research. These aspects are all treated too briefly to be of much value.

The book tends to lack structure and continuity which is to be expected when there are so many contributors. I find it disappointing, however, that such an important topic which involved many important people for several days is reported in what is relatively a short book. Nevertheless, there is some extremely important information in the book which makes it worth reading for all who are in any way concerned with research policy decisions in the applied sciences.

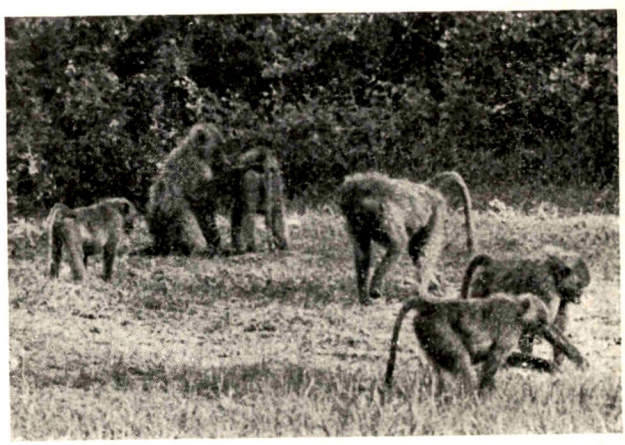
T. R. WILSHAW

Biological Sciences

BABOON ECOLOGY IN KENYA

Baboon Ecology

African Field Research. By Stuart Altmann and Jeanne Altmann. (Bibliotheca Primatologica No. 12.) Pp. vii + 220. (Karger: Basel; University of Chicago Press: Chicago and London, 1970.) SFr.45; 108*s*.



THE realization of the theoretical importance of baboon ethology and ecology for the inferential analysis of the early history of the human species has been accompanied by an enthusiasm for theory and speculation which, although often of undoubted heuristic value, has lacked adequate foundation in hard fact. Although good hypotheses provide guide lines for research only data, often brutally won by physical effort in an uncompromising habitat, can yield the information with which they can be tested. This monograph by the Altmanns does much to improve the factual side of the baboon saga and it is an important continuation of the field studies carried out in Africa during the past decade by, among others, Sherwood Washburn, K. R. L. Hall and Irven DeVore.

After a widespread survey, the Altmanns chose the Amboseli Game Reserve in Kenya as their principal field study area. Here they settled to complete a study that lasted from June 1963 to August 1964. Although the duration of their field study was not exceptional the volume of data collected demonstrates the authors' intense devotion to field work and a well organized method of data acquisition. This monograph is concerned with the ecological aspects of the investigation—reports on behaviour and social organization are in preparation.

The story begins with a detailed account of the local baboon groups (*Papio cynocephalus*), their population dynamics, group size, birth, death, and emigration rates and problems of group composition, sex-ratio, group fission and the inter-troop movements of individuals. Observations on sleeping behaviour follow and the daily ranging is described. The progression rate of foraging animals on daily ranges, patterns of aggregation and dispersal, home range size, overlap and exploitation are mentioned together with an account of seasonal contrasts. Dietary and water requirements and acquisition are examined together with social aspects of feeding in a section that slightly disappoints because so far there is no detailed analysis of social behaviour in relation to precisely quantified variation in the seasonal availability and nutritional quality of food. As the authors indicate, this indeed must be the next step in field primatology. Predation on the baboons of Amboseli, especially by leopards, is not uncommon and the Altmanns provide observations of a largely anecdotal kind. The monograph ends with general observations on the baboon's relations with other animals and a speculative chapter. At the end of most chapters there is a comparative section relating the Amboseli data to studies on other populations of the genus—sometimes accompanied by overlengthy quotations from other writers.

Some highlights of the Altmanns' survey are as follows. In contrast to most other studies the Amboseli male baboons show considerable evidence of movement between groups. Some males, furthermore, evidently remain isolated for a period which may be associated with the timing of a change in group membership. This isolation occurs in spite of the demonstrable dangers from predation in the Amboseli environment. Migrations of individuals between groups may be an important factor affecting sex ratios in different groups. Only adult males are known to show such migration and this seems to be associated with a higher mortality. The Altmanns state that there were a calculated $1{\cdot}916 \times 10^{-3}$ deaths per monkey-day for males but only $0{\cdot}256 \times 10^{-3}$ for females.

Amboseli baboon groups sometimes congregate in certain groves for sleeping, indicating a pattern of inter-group behaviour hitherto reported only for the congeneric hamadryas baboon in Ethiopia. When foraging, members of a group often show far less cohesion than earlier reports have suggested. At times, groups become spread out in long lines or are widely dispersed, but members congregate during encounters with predators,

Baboons (*Papio anubis*) in arid country in the Awash Valley, Ethiopia. Although a different species these baboons are similar in appearance to the animals studied by the Altmanns.

when approached by another group, when traversing unfamiliar terrain or when in heavy undergrowth. In open familiar terrain individuals often become much dispersed. In view of the often grossly exaggerated popular accounts of the significance of animal territory for human behaviour it is worth stressing that the Altmanns' baboons showed "no convincing evidence for territoriality, in the sense of a defended area". This seems to be true generally for open country primates most similar in many behavioural respects to man.

The Altmanns noted that their baboons prey on insects, worms, reptiles, birds' eggs and chicks, hares, a fossorial rodent, a young Grant's gazelle, vervet monkeys and bushbabies. True hunting and chasing were recorded, particularly from certain individuals who appeared to be adepts. After the capture of meat there were often agonistic encounters over its possession which were settled apparently according to the social status of the disputants. Rarely do baboon watchers observe actual attacks by predators on their animals nor the defensive behaviour that may sometimes be shown. The Altmanns recorded cases in which males and sometimes also females lunged at or chased a predator, and they also observed a new response to the appearance of a predator—crouching cryptically and motionlessly in the grass. The records of a degree of cooperative defence are important for their occurrence has sometimes been denied. Such events have also been seen in the Patas monkey in a comparable African habitat.

This study confirms the impression that baboon social life is rich and that the relation between social dynamics, population dynamics and ecology comprise for these animals a complex system that will require long-term quantitative investigations of known marked populations over several years, supplemented by experiments on separate test populations. Until primate ecology reaches the standard of comparable work with birds much will remain mysterious. But monkeys are not birds and we can glimpse already the elements of the socio-ecological system which, on a parallel track, was to lead eventually to man.

This study is essential reading for primatologists, social ethologists and anthropologists and can be read with profit at any stage of an individual career.

JOHN H. CROOK

CHIMPANZEE TOPICS

Physiology, Behavior, Serology, and Diseases of Chimpanzees

Edited by G. H. Bourne. (The Chimpanzee, Vol. 2.) Pp. x+417. (Karger: Basel and New York, 1970.) 115 francs; 230*s*.

THE chimpanzee has, for long, attracted scientific attention, principally because of the well documented view that, along with the gorilla and orang-utan, it is structurally and functionally most closely related to man. Morphological study of the chimpanzee dates from Tyson's publication in 1699 of the *Anatomy of a Pygmie*, but the foundation, on an appreciable scale, of pioneering studies of the physiology and behaviour of this genus, dates only from the 1930s. Because the animal is relatively big and presents other difficulties in its husbandry, research into chimpanzee physiology and behaviour is still limited although, in common with work on other primate groups, its study has received impetus during the past decade following the establishment in the United States of America of centres for primate research, and with the elaboration of the space research programmes.

This volume is the second of a planned series designed to form ultimately "a comprehensive study of this species". As a matter of editorial policy, subjects are dispersed, each volume having "a selection of chapters dealing with a variety of aspects of the study of the chimpanzee". The result is that this volume, like its predecessor, covers a big and seemingly disconnected variety of topics ranging from studies in visual physiology, through analyses of renal function, energy metabolism and body temperature, to an examination of the chimpanzee's taste modality. Morphological studies comprise a significant section of the work and include a formal description of the spinal cord of the chimpanzee. This is followed by an exemplary analysis of the limbs, carried out in the now established tradition of inquiring quantitatively into correlations between, on the one hand, form and structure and, on the other, locomotor and other functional uses.

The chromosomes of the animal are next considered and this study is followed by chapters dealing with social and other types of chimpanzee behaviour. The now well known modern work on chimpanzee serology is summarized, and the volume concludes with two chapters aimed towards an advancement of the husbandry of the species, and dealing first with the viruses pathogenic to chimpanzees and second with the isolation of mycoplasmas.

Comparison with other primate genera—even those for which reasonable amounts of information are available—is, of necessity, limited. Nevertheless, comparison with man and sometimes with the other apes understandably permeates most contributions, and here two contrasting groups of findings emerge. In some fields, for example adaptation in the limbs, the chimpanzee is very different from man. In many other fields—including some as fundamental as studies of the chromosomes—there is, in spite of some contrasts, a great similarity between this ape and man. In the case of the "genetically informative macromolecules" the similarity is such as to depict (in this one feature) "a closer genealogical relationship of the African apes to man than to the Asiatic apes".

The synthesis of such contrasting information to provide a basis for assessing evolutionary relationships is a problem now developing in both concept and methodology. Its solution could well be the responsibility of a future generation.

E. H. ASHTON

ATLAS OF AFRICAN BIRDS

An Atlas of Speciation in African Passerine Birds

By B. P. Hall and R. E. Moreau. Pp. xv+423 (439 maps). (British Museum (Natural History): London, 1970.) 300*s*.

To quote the foreword by Professor Ernst Mayr, this is "a superb achievement". It represents the gigantic task of plotting, for 962 species, the localities recorded in the extensive literature and in data of principal museum collections. The information is very clearly presented by symbols on a series of identical maps; further, it is arranged in a meaningful way, so that the atlas is very much more than an assembly of study material. The theme is the superspecies, or in some cases the wider species group, and all the species belonging to any one such category are shown together on a single map. The grouping of species in this way is of course a matter of taxonomic judgment, but the authors' reasons are duly given in the text. Of the total, 176 species are ranked as standing alone and are separately mapped.

Each map, with its explanatory text, occupies a page; and, where practicable, closely related groups are allotted facing pages. The species included are the members of the Passeriformes breeding in continental Africa south of 20° N latitude. (Non-passerine birds were found, in general, to require treatment on a world rather than a regional basis and have therefore been wisely excluded from the scope of the work.) Species peculiar to Mada-

gascar and other islands have been omitted, except in the small minority of instances where they represent superspecies of which other forms are truly African. In the case of superspecies of wide distribution, inset maps of the world are provided to show the extra-limital representatives. The production of the large volume is excellent.

Nothing of the kind on this scale has been done for birds before. The earlier studies of evolution and speciation, from those of Darwin and Wallace onwards, were made on island populations, for which boundaries were predetermined and tended to remain stable, so that the outcome of segregation was often diagrammatic in its clarity. In a continental area the situation is apt to be much more complicated; and secondary changes in the environment produce secondary effects in the distribution of the avifauna. Keast had lately shown, however, that similar methods of study could be applied to Australian birds; and Mrs Hall herself had done it for the francolins of Africa. Here she has given an exposition on a grand scale, and with most impressive results.

She received much help and advice from the late R. E. Moreau, whose own work had documented the history of climate and vegetation in Africa in their relevance to the avifauna. The contraction and expansion of vegetation zones fracture the originally continuous distribution of avian (and other) species, and the resulting segregations lead to fresh speciation. Later, further changes in the environment bring the isolates into secondary contact, and various patterns emerge. The study of these last offers rich scope for further research, particularly by the field worker. Here is a firm basis for it; and case after case pose an intriguing problem.

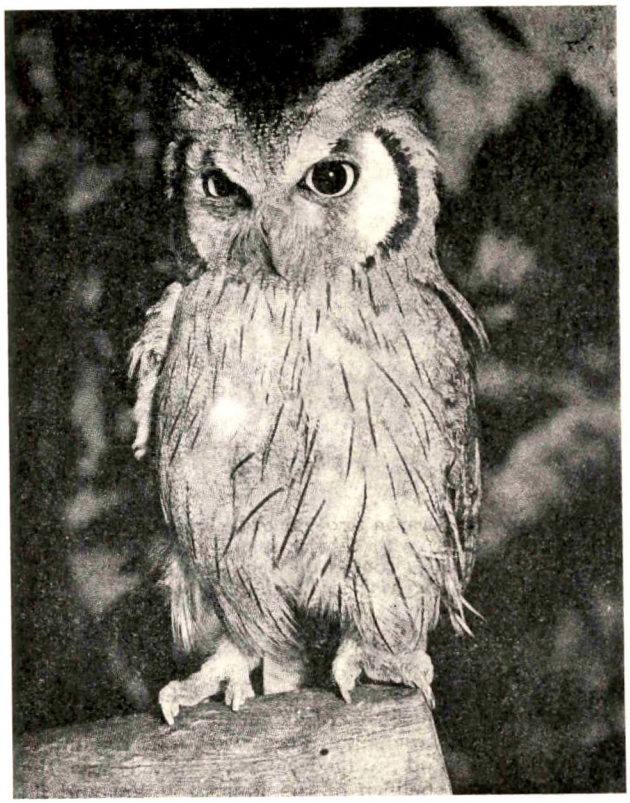
A. Landsborough Thomson

ENCOUNTERS WITH SHARKS

The Shark

Splendid Savage of the Sea. By Jacques-Yves Cousteau and Philippe Cousteau. (The Undersea Discoveries of Jacques-Yves Cousteau.) Pp. 277. (124 photographs in colour.) (Cassell: London, October 1970.) 50*s*.

In February 1967 the Calypso sailed from Monaco to collect material for a series of television films on the sea. This book is the first of a series of six commissioned by Cassell, each of which will deal with a particular aspect of the work undertaken on this voyage: coral reefs, shipwrecks, whales and archaeology are the subjects of the next four volumes.



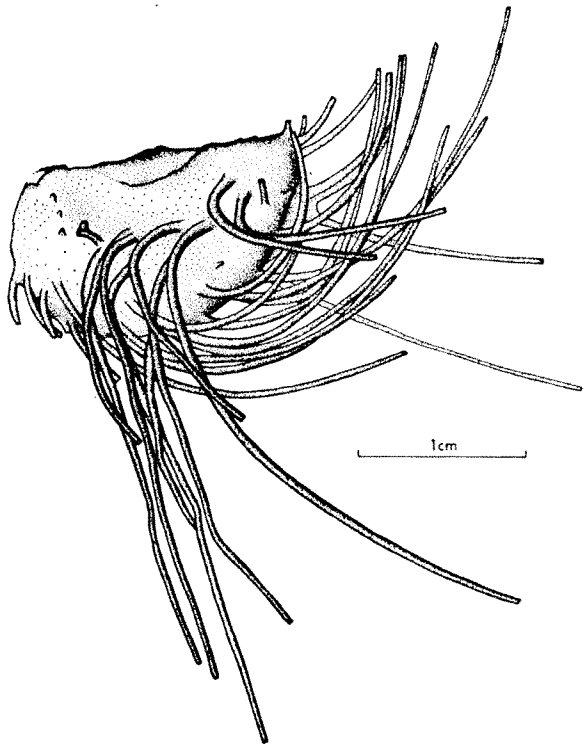
Many people who have enjoyed Cousteau's films may want to know more about them. Cousteau's introduction makes the point that the films tell little of the technical and personal problems, difficulties, and triumphs involved: these books are to complete the picture. This book is not a scientific account of sharks and this can never have been the authors' intention: it is not set at a lower level but rather in a different direction. The two Cousteaus—father and son—adopt a narrative style to highlight some of the expedition's encounters with sharks in the Red Sea and Indian Ocean and they do it rather well. I was impressed by a simple account of a submarine dive near Socotra (pp. 181–8); and there can be few readers who will not be astounded by the description and photographs of the whale sharks. Not unexpectedly, much of the book is centred on or returns to the shark as a predator: there is a lot of biting and a lot of blood. Equipment, ship and crew are described and figured. I noted, with envy, that the Calypso carried a first-class cook and a maître d'hôtel!

The text is translated from the French and generally reads well. But here and there dates and places jump. There seems to be a confusing break in continuity on p. 180. The principal part of the text is printed on glazed paper and the layout is pleasant. But the production standards are not maintained in the last 40 pages which are unglazed and include an adequate index and twenty-two line figures. In the figure section the pages are confusingly see-through and are not numbered. The colour photographs vary in quality and some show a surprising amount of red which may result from using artificial illumination of a spectral composition inappropriate to the depth of water. But as a whole the book is good value for money.

This book, and the others to follow, should interest a wide public and libraries may expect a waiting list for their copy. The biologist will find some interesting observations: attacks on sharks by porpoises; evidence for territoriality in reef sharks; and the presence and behaviour of mice, hawks, and hermit crabs on the island of Derraka. But after reading the book I had the unhappy feeling of having been cheated: so much spectacle, so little measured. For example, the Cousteaus must have hundreds of metres of film on the movements of sharks. But has there been any attempt to relate fish length and swimming speed to tail-beat frequency? What I really want is another sort of book. Calypso sailed from Monaco, a town which I associate, not with the Grand Prix, but with Prince Albert's *Résultats des Campagnes Scientifique accomplis sur son Yacht*. May we yet look forward to a similar series, albeit less munificent, from Cousteau and his Calypso?

F. R. Harden Jones

A PARLIAMENT OF OWLS



A white faced scops owl (*Otus leucotis*), one of more than 130 species of owl, some very rare, which are to be found around the world. The natural history of these curious birds of prey is told effectively by John Sparks and Tony Soper in *Owls* (David and Charles: Newton Abbot, October 1970, 50s), a book which should appeal to the naturalist and the general reader alike.

BRACHIOPOD EVOLUTION

Living and Fossil Brachiopods

By M. J. S. Rudwick. (Hutchinson University Library: Biological Sciences.) Pp. 199. (Hutchinson: London, October 1970.) 38*s* boards; 16*s* paper.

IT is surely a gamble to publish a general account of a phylum within five years of having collaborated with several other specialists in an exhaustive study of the same group. On the one hand the book might turn out to be an indigestible if deferential summary of authoritative fact and opinion written with an eye on omission rather than content. (How many of us judge the soundness of a paper by the number of honourable mentions we receive in the bibliography?) On the other hand it might be a defiant declaration of cherished beliefs embarrassingly free of the constraints of other researchers' observations. Occasionally, however, when an author like Dr Rudwick skilfully redeploys well known facts and assembles new information to illustrate novel aspects of phyletic evolution, the gamble comes off and the rewards are rich.

Lateral view of a Permian strophomenide brachiopod (*Marginifera* Productacea) with tubular spines on ventral valve: these spines probably rooted the shell in a soft substrate (Fig. 46, in *Living and Fossil Brachiopods*).

The originality of Rudwick's approach is his exploration of the functional implications of changes in shell morphology that arose during brachiopod evolution. The phylum is modestly represented in modern seas, but it was the dominant marine shellfish of the Palaeozoic era and its fossil record is remarkably complete back to the early Cambrian. This unrivalled range of living and extinct species has been well exploited in this book in chapters devoted to each of the basic functions that can be related to exoskeletal features like "muscles and hinges", "senses and protection", "lophophore and feeding", and so on. In these chapters of clearly written text and well designed illustrations, Rudwick shows how feasible living and working models may be derived for the shells of even the most bizarre of extinct species. There are abundant new data here, such as the ontogeny and disposition of setal grilles and the correlation of columnar muscle with the development of accommodating skeletal platforms. Indeed, every chapter contains an instructive phyletic chart based on brachiopod superfamilies indicating the range of features associated with a particular function. The sections on the "classification of brachiopods" and "history of the phylum" are less effective because parts of his classification, like the assignment of the Thecideacea and certain spire-bearing genera to the Strophomenida, are contrived and disputable. Yet they do serve to emphasize the personal flavour of the text and in that respect do not detract from the merits of a book that can be unreservedly recommended for its scholarship, originality and presentation.

ALWYN WILLIAMS

TENTACLED FLOATERS

The Medusae of the British Isles

Vol. 2: Pelagic Scyphozoa, with a Supplement to the first volume on Hydromedusae. By F. S. Russell. Pp. xiii + 281 + 15 plates. (Cambridge University: London, October 1970.) 140*s*.

EVER since the eighteenth century British marine biologists have found the coelenterates most rewarding objects of investigation. John Ellis was the first to demonstrate that zoophytes were ramifying animals, and John Graham Dalyell could have forestalled Michael Sars as the discoverer of alternating generations had not publication of his observations been delayed. The young T. H. Huxley, studying tropical zooplankton during the voyage of the Rattlesnake, first revealed the two-layered structure of these members of the "Radiata". Later workers were no less fascinated by the wealth of form and beauty and the range of adaptive radiation exhibited by these simply constituted animals. The beautifully illustrated memoirs of Forbes, Hincks, Gosse, Allman and Alan Stephenson come readily to mind.

F. S. Russell joined this distinguished company in 1953 with the publication of the first volume of his *Medusae of the British Isles* which dealt with the Hydromedusae. His second volume, here reviewed, deals with the pelagic Scyphozoa with a supplement which brings the subject matter of the first up to date, largely by the association of more medusae with the hydroid generation.

This is a model of what a taxonomic memoir should be, gaining undoubtedly by the few species demanding study. Out of about one hundred and sixty known species of these larger jellyfish, only thirteen are British. Six of these occur inshore, the remainder in oceanic waters off the continental shelf and often at considerable depths. All are subject to exact description in words aided by explicit text-figures and by both coloured and black-and-white plates. Apart from taxonomic distinctions, synonymy and full anatomical description including variations, there is a wide survey covering habits, physiology, life history and distribution.

Few animals are better known to the shore naturalist or more certain of comment by all who encounter them than the inshore species, the pale saucer-like *Aurelia aurita* occurring widely in many seas, the brown bell-like *Chrysaora hysoscella*, the two species of *Cyanea*, the brown *C. capillata* and the blue *C. lamarckii* with bunched tentacles and widely spreading, frilled manubria. The first of these, the lion's mane, has a formidable sting and mention is here made of its encounter by Sherlock Holmes although—probably the sole omission in the comprehensive bibliography—not of the more sinister de-

ductions from the evidence suggested by J. W. Hedgpeth[1].

The more solid *Rhizostoma octopus*, normally confined to southern and western coasts, has the manubrial opening divided into a complex series of minute openings along the ramifying oral arms admirably fitting the needs of a jellyfish feeding on the smaller members of the zooplankton. The hemispherical, thick jellied and luminescent *Pelagia noctiluca* is less common inshore but occurs occasionally in swarms.

The oceanic species of *Nausithoë*, *Atolla*, *Paraphyllina* and *Periphylla* are fully described and illustrated although, inevitably, far less is known about their biology, notably their life histories. A most significant section of the British marine fauna receives definitive treatment in this handsomely produced volume and all marine biologists are in debt to Sir Frederick Russell. C. M. YONGE

PLANT ULTRASTRUCTURE

Electron Microscopy and Plant Ultrastructure

By A. W. Robards. (European Plant Biology Series.) Pp. 298. (McGraw-Hill: Maidenhead and New York, September 1970.) 72*s*.

PLANT ultrastructure is at last becoming quite well covered by textbooks of a variety of levels. This book aims at the level of the undergraduate course, and sets out to describe both plant ultrastructure and the methods by which it is studied.

The first part of the book deals with the electron microscope and its ancillary techniques. The electron microscope is covered clearly and straightforwardly, though with some unnecessary passages about historical development and constructional details. The micrographs showing the effects of over and under focus and astigmatism are particularly useful. The chapter on techniques describes adequately most of what it covers, but has some serious omissions. Negative staining is dismissed in a few lines, differential centrifugation is not described at all, and the section on freeze-etching makes no mention of antifreeze agents or prefixation. This is particularly regrettable because the results of these techniques are well dealt with in the rest of the book.

The following chapters are each devoted to a single organelle or group of organelles. In his introduction to each topic, Dr Robards tends to forget his readers. A botany undergraduate is not likely to need a table showing him the principal groups of plants and microorganisms, nor the information that heterotrophic angiosperms exist. This will tend to put off potential readers, but it should not, for Robards's ultrastructural descriptions are excellent. He details the structure, as elucidated by various means, of each organelle, and describes what is known of its function. He does not gloss over controversy, but discusses both sides fairly. The only fault is a slight shortage of photographs, presumably on grounds of economy, even though lithographic reproduction is used. The photographs are, however, well chosen, and there is an abundance of line diagrams.

There follows a chapter giving a comprehensive but cursory survey of the specialized structure of different cells. As the author rightly points out, it would be impossible to do more in a work of this scale. The remaining chapters, on algae, fungi, prokaryotes and viruses, have been contributed by J. D. Dodge, R. Marchant and D. G. Smith. Each is an excellently clear account of the chief ultrastructural features of the group concerned. Although microorganisms have been extensively used in investigating specific problems, their general ultrastructure tends to be inadequately covered in textbooks.

The book as a whole is very readable: it is also useful as a reference book because of its comprehensive index, a detailed contents list and a straightforward layout. I hope the tendency to talk down to the reader on general topics does not antagonize potential purchasers, for the important part of the book, the description of ultrastructure, is an excellent advanced and up to date text.

GUY COX

INSIDE THE FLOWERING PLANT

The Physiology of Flowering Plants

Their Growth and Development. By H. E. Street and Helgi Öpik. Pp. viii+263. (Arnold: London, August 1970.) 70*s* boards; 35*s* paper.

THERE is currently almost an embarrassment of simple and attractive volumes available to introduce the absolute novice to the flowering plant and its problems. The advanced student and the specialist are similarly well catered for, but what Professor Street and Dr Öpik have done so well is to combine the best features of each of these extremes into an excellent intermediate text; a guide to plant physiology for those who already have some knowledge of plant anatomy, biochemistry and biophysics. Indeed such prior knowledge is essential, for unlike so many other plant physiology texts, the authors have confined themselves strictly to physiology. Little space is spared to introduce, for example, basic plant biochemistry, or to develop the concept of metabolic pathways.

The authors have obviously tried hard to make their book easy to read, and they have succeeded. It is rare to find an introductory textbook which is quite so enjoyable, either to study for information or for merely browsing through for interest. In addition to chapters on the more usual subjects such as germination, water relations, mineral nutrition and growth, due emphasis is given to such neglected topics as frost and drought hardiness and energy economy. Other chapters cover transport of metabolites, growth, cell differentiation, growth movements and morphogenesis. Each subject is developed in sufficient detail to satisfy the needs of the first or second year undergraduate, and a short list of the more important references and a guide to further reading are given at the end of each chapter.

The book has been nicely laid out and the figures are clear, but it is a great pity that the volume could not have been more attractively bound. If it sells as well as it deserves to, it will owe nothing of its success to the drab olive green colour of the cover (why must botanical texts be bound in green ?) or to the uninspiring design with which it is ornamented. ALAN CANE

REVIEW OF GENETICS

Advances in Human Genetics

No. 1. Edited by Harry Harris and Kurt Hirschhorn. Pp. xi+339. (Plenum: New York and London, 1970.) $19.50.

As the editors say in their preface to this volume, original papers dealing with different aspects of human genetics are appearing so frequently and in so many journals, and result from investigations originating in so many different disciplines, that there is a real need for critical review articles which summarize the positions reached in different areas. This first volume of a new series contains five such articles.

As might be expected with editors of this distinction and experience, the authors of the five chapters are well chosen and briefed, and each chapter is a mine of infor-

mation and references. The first, by J. H. Edwards, is on the analysis of pedigree data. It is less a review of work in this field than a formal analysis of the scope and limitations of the method. It is stimulating, and will repay reading by anybody concerned with pedigree data; but they should not expect a practical manual on the techniques available.

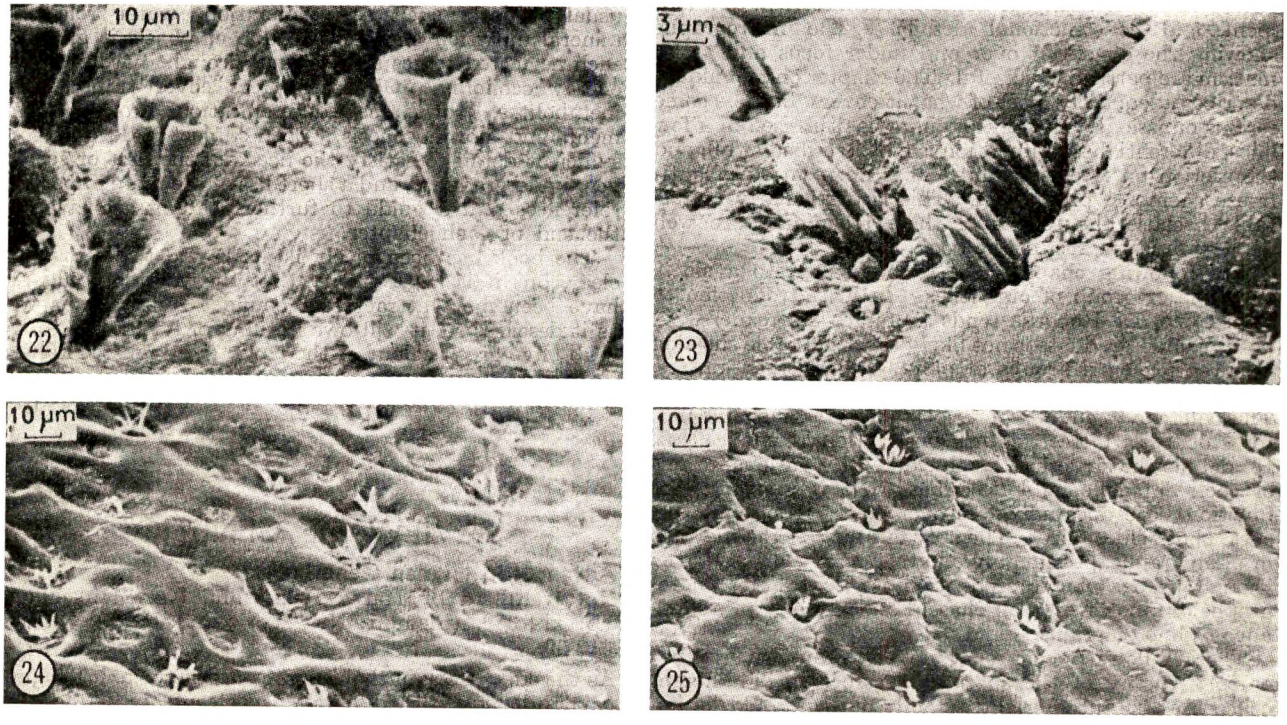
The second chapter, by Orlando J. Miller, on autoradiography in human cytogenetics, is a thorough and wide-ranging review, covering almost any conceivable aspect of the application of autoradiography to the study of chromosome identification, structure and replication. Cytogeneticists will find it invaluable.

The third chapter, on the genetics of immunoglobulins, by H. Hugh Fudenberg and Noel E. Warner, is likewise a thorough and highly technical review of the immunoglobulins, and of their chemical, structural and immunological features in relation to their genetics.

The fourth and fifth chapters overlap and complement each other. The fourth, by Charles R. Scriver and Peter Hechtman, on human genetics of membrane transport with emphasis on amino-acids, describes the mechanisms and specificity of such transport, together with a consideration of the genetic loci involved, and includes a section on treatment and counselling. The fifth, by Jean Frézal and Jean Rey, on the genetics of disorders of intestinal digestion and absorption, is a description of the clinical and chemical-pathological findings in genetically determined disorders of this sort; there is little formal genetics, but much of the ground has already been covered in the previous article.

The quality of production of this book justifies its price. There are few typographical errors considering the technical nature of the material. If subsequent volumes maintain the standard of this one the series will be a memorable one.

E. H. R. FORD



MEANINGFUL MESSAGES

The Molecular Basis of Mutation

By John W. Drake. Pp. 273. (Holden-Day: San Francisco, February 1970.) $15.00.

"ONE of the most potent mutagens described to date for microorganisms is Adelberg, Mandel and Chen, 1965." This excellent, unintentional example of a deletion mutation resulting in a different but still meaningful message is taken from p. 155 of this book and is rather better than the deliberate examples given on p. 83. Mutations are, in fact, largely rearrangements within an encoded message and consideration of their molecular basis is the author's aim. The time is ripe for such a book, and this one will go a long way to fill the gap which

INSECTS UNDER THE MICROSCOPE

There is strong evidence that the setal receptors found between the ommatidia in the compound eyes of many adult insects are extensions of the receptor system of the head on to the eyes. These scanning electron micrographs, taken from a paper "Some Little Known Surface Structures" by H. E. Hinton in *Insect Ultrastructure* (edited by A. C. Neville for the Royal Entomological Society of London, Blackwell (Scientific): Oxford and Edinburgh, 1970, 70s), show some of the setae found on the head and between the ommatidia of some species of aquatic bugs of the family Naucoridae. In this family different genera have quite different kinds of cephalic sensilla and in each genus the kind of sensillum on the head is also present between the ommatidia. In *Cryphocricos mexicanus*, the cephalic setae are trumpet shaped (Fig. 22) and those between the ommatidia are also trumpet shaped but are smaller. In *Heleocoris mexicanus*, the inter-ommatidial sensilla (Fig. 23) consist of tufts of closely appressed setae that are precisely like those of the head. In *Aphelocheirus aestivalis*, the cephalic setae (Fig. 24) are also tufts of setae but the setae in each tuft are widely divergent. The inter-ommatidial setae are almost similar in form (Fig. 25).

exists. It is aimed at graduate students and professional investigators, especially those entering the field of molecular biology from other disciplines. The first part is indeed a joy, with lucid expositions of basic facts and ideas of molecular biology which surpass those in more explicitly educational books. The professional investigator, however, demands more than this, particularly where current problems and research are concerned, and it is here that the book's limitations are seen. Dr Drake's reputation as a geneticist rests primarily on his work with bacteriophage T4. The fact that he has naturally chosen to concentrate on this organism is both the strength and weakness of his book. The importance of T4 is obvious in those sections dealing with the principles of molecular genetics. T4 is, however, an organism largely independent of the cellular functions of its host and the ways in which mutations arise in it are often different from those of bacteria and even most other bacteriophages, particularly with regard to the involvement of repair and recombination processes. The connexion between recombination genes and mutation in bacteria has been a profitable field for several years and the scant attention which it receives exemplifies the book's relative neglect of the involvement of cellular processes in mutagenesis.

There are several errors (for example, in the report of the work of Kada and Marcovich on p. 161) and omissions (for example, the discoverers of the potent mutagenic action of nitrosoguanidine, Mandell and Greenberg in 1961). Nevertheless, it is a book to be commended as a reasonably elementary guide to mutation, particularly for first degree students in their final year and predoctoral workers. An interest in mutation is not out of place in a world which man is making more mutagenic than at any time since the ozone layer began to shield it from the worst effects of the Sun's radiation.

BRYN BRIDGES

MACROMOLECULES AND GENES

The Molecular Basis of Gene Expression

By Benjamin M. Lewin. Pp. x+446. (Wiley (Interscience): London and New York, August 1970.) 130*s* boards; 70*s* paper.

WITHIN the past decade important advances in microbial genetics, protein biosynthesis and nucleic acid biochemistry have greatly enhanced our understanding of the functioning of the genetic material, particularly in relation to control mechanisms in prokaryotic cells. As those involved in teaching or research in this field will be well aware, the rate of progress has been so rapid that it is difficult to keep fully abreast of new discoveries and their significance. The task of integrating recent developments into a coherent body of knowledge is therefore both formidable and important.

This account by Dr Lewin of the interrelationships of macromolecules involved in gene function is a timely and welcome addition to the comparatively few books in this important field. The scope of the book has been deliberately restricted chiefly to bacterial systems, which is reasonable because relatively less is known about the expression of genetic information in higher organisms. It is a pity, however, that the discussion of the control of the synthesis of multi-chain proteins such as haemoglobin and immunoglobulin is not a little more detailed.

Many of the recent developments discussed in this book are based on experimental work which is often highly sophisticated both conceptually and technically. On the whole, the presentation of intrinsically complicated material is clear and intelligible, but a good background knowledge is an advantage if not essential at times. For this reason, the book is most suitable for postgraduate and advanced undergraduate students, and for research workers active in this area. A glossary of technical terms would be of help to the reader, and perhaps this can be added in a future edition. Another aspect which could with advantage be covered more fully is the molecular basis of mutations.

There are few major errors, but the description on p. 93 of the procedure used by Dintzis for investigating the sequential synthesis of haemoglobin peptides is not entirely accurate; ribosomes in eukaryotic cells are not always attached to endoplasmic reticulum as suggested on p. 96; and the mechanism of action of puromycin is rather different from that which appears to be implied on p. 135. Several minor mistakes, for example the numbering of the pyrimidine ring (p. 25 and Fig. 2. 1), the spelling of several authors' names (pp. 171–173), the concentration of magnesium at which ribosomes dissociate into subparticles, which is much lower than that given on p. 96, will, I hope, also be corrected on a future occasion.

On the whole, however, this is a well written and worthwhile book which will serve a useful purpose and it can be highly recommended.

H. R. V. ARNSTEIN

CONJUGATION MECHANISMS

Metabolic Conjugation and Metabolic Hydrolysis

Vol. 1. Edited by William H. Fishman. Pp. xv+461. (Academic: New York and London, August 1970.) 261*s*.

MANY organic compounds administered to animals are excreted in the urine or bile in conjugated form and it was long thought that this is largely a process of detoxication. There is now evidence, however, that hormones and other bodily constituents are likewise coupled with glucuronic acid, sulphate or other groups, so that the term "metabolic conjugation" has been introduced. The view has developed that a balance between conjugation in certain cells and cellular compartments and hydrolysis in others has important effects on the physiological and pharmacological activity of hormones and drugs. This is the first of three volumes devoted to an authoritative account of these reactions.

R. L. Smith and R. T. Williams describe the history of the discovery of conjugation mechanisms. Although this information has been available elsewhere, notably in Williams's book, *Detoxication Mechanisms* (Chapman and Hall), it is here conveniently summarized. D. S. Lane describes new metabolic conjugates of steroids, including coupling with N-acetylglucosamine and glucose, acetylation, phosphorylation, methylation and combination with glutathione. Variant forms of glucuronic and sulphuric acid conjugation also remind us that biological reactions are seldom simple. C. C. Irving discusses conjugation of N-hydroxy compounds which are of special interest in cancer induction. It is often thought that conjugated hormones are biologically inactive, but M. Mason summarizes work showing that conjugated steroids can bind with and affect the function of enzymes and other proteins. A comprehensive review of the glucuronic pathway of conjugation is given by T. A. Miettinen and E. Leskinen, and sulphoconjugation and sulphohydrolysis are described by K. S. Dodgson and F. A. Rose. The lysosomal localization of many intracellular enzymes that can hydrolyse mucopolysaccharides is reviewed by E. A. Davidson. Although much useful information has accumulated, there are unsolved problems such as the nature of the enzymes breaking down dermatan or keratan sulphates and the exact defects in storage diseases such as Hurler's and Hunter's syndromes. The final chapter by J. L. van

Lancker on hydrolases and cellular death emphasizes how little is known about cell damage and death: whether release of hydrolases is primary or secondary in many instances, and what part the hydrolases play in normal and increased protein turnover.

In general, this book provides a useful account of the current state of knowledge about metabolic conjugation, although much of the ground is already familiar. The three volumes taken together will doubtless provide a standard reference, though the chapters on topics in which ideas are most rapidly changing, for example the role of lysosomes in cell damage, are likely to become dated within a few years. A. C. ALLISON

STUDENT IMMUNOLOGY

Basic Immunology

By E. R. Gold and D. B. Peacock, with chapters by J. Verrier Jones, T. E. Blecher, M. O. Symes and W. J. Harrison. Pp. xii+416. (Wright: Bristol, June 1970.) 90*s*.

IMMUNOLOGY continues to recruit a steady stream of students at various levels and from various sources, many of whom, in spite of avowed special interests, sooner or later begin to feel the need for a wider grasp of immunological concepts. A textbook of "basic" immunology might be judged, then, at least in part, by how far it succeeds in meeting this need. The textbooks that have appeared so far (with one or two deservedly well known exceptions) tend to suffer from a plethora induced by the unselective inclusion of too many facts and observations, squeezing out the important consideration of how we are to make the best sense of them in relation to each other, and of how the many questions that follow may best be framed.

This book's success with this problem is less than complete—perhaps because coming from six different pens it forfeits a unified approach. From the students' standpoint, the best chapters are undoubtedly those on the production of antibody and on cell-mediated immunity and delayed hypersensitivity, which describe some of the most telling experimental and clinical observations, and by critical discussion and pertinent questioning build up a clear picture of present trends in thinking about these two basic immune activities. In another chapter the *in vitro* correlations of cell mediated immunity are carefully enumerated, but less critically evaluated, so that the "exciting vistas" this work foreshadows show up less clearly than they should.

The chapter on immunoglobulins gives a straightforward account of modern knowledge of their molecular structure and the significance of its variations, but it perhaps assumes too much knowledge or insight in the reader, who, to give one example, might well have some difficulty in grasping the meaning of the Valentine diagram for IgG, given only the background of the text. On the other hand, few students would require the detailed chemical and isomeric analysis of antigenic determinants provided here.

So far as immunopathology goes, there is a useful summary in the section on autoimmunity, which is largely clinical in context. It is in this section that one of the two paragraphs in the book on the biological significance of immune complexes occurs—a surprising lack, because this is a part of immunopathology about which we know something, and which seems now to play an even more important part in disease than was once thought. It is in this section, too, that the subject of immunological tolerance appropriately, though scantily, receives attention. Other aspects of immediate hypersensitivity are discussed elsewhere in the book, and there are chapters also on complement, transplantation immunity and tumour immunology. The book is perhaps likely to appeal most to the reader seeking a ready aid in refreshing rather than extending his basic knowledge of immunology. E. J. HOLBOROW

24 HOUR CLOCKS

Human Circadian Rhythms

By R. T. W. L. Conroy and J. N. Mills. Pp. ix + 236. (Churchill: London, 1970.) 60*s*.

THE more than exponential increase in scientific information causes such bewilderment that many reviews of a field are no more than catalogues of possibly related items. Papers can easily be referred to by the dozen and yet not studied critically for their content and limitations. *Human Circadian Rhythms* by Conroy and Mills, however, is refreshingly different. The authors have limited their aspirations to what they can reasonably achieve. Their style is direct and clear. It will be only apparent to those familiar with some of the field that the authors have carefully studied the tables and graphs of other authors. In doing so they have been able to assess the significance of the findings and they have wisely erred on the side of demanding real evidence for conclusions.

The book is largely a development of Mills's classical article in *Physiological Reviews* in 1966. It is at best in the chapter on the kidney. This chapter contains a lucid account of the real difficulties in establishing that, for example, the adrenal cortical rhythms control sodium and potassium excretion. It is a model for scientific writers.

The work is, in effect, in three parts. After an initial discussion on methods and a critical consideration of the inevitable limits of studies on humans there is an account of the twenty-four hour rhythms established in man and their persistence without time clues and on non-twenty-four hour schedules. This second part is the most detailed and is followed by a concluding and shorter attempt to assess the practical significance of the work which has been carried out.

The writers at every turn occupy themselves with the question of how far the rhythms of the variable discussed are endogenous. They consider the synchronization which occurs during development and the interesting desynchronization which can arise from shifts of phase and activity and lightning schedules. There is no evangelism in the whole work. One is left with the findings and the various claims of other writers plus apt comments on the possibility of alternative and more parsimonious views.

The ubiquitous nature of approximately twenty-four hour measuring systems in living organisms, the presumably fundamental nature of the clock-like processes at the molecular level, and the observations dealt with in this book show how far we have already entered a field which will illuminate much in biology. It already seems likely that related processes affect eclosion in *Drosophila*, the opening and closing of some flowers and the human renal excretion of potassium, and so on. This is relevant to night watchmen's efficiency, to diagnosing Cushing's syndrome, to designs for space flight, and the laying of eggs by chickens.

Conroy and Mills mention very briefly work on the possibility that processes in the production of RNA are the central timing device, and that the hypothalamus in man contains the master clock. The book is, however, chiefly concerned with what has been shown in studies on man himself; the wilder flights of speculation are left for the reader. These he can more aptly pursue after reading an excellent book. F. A. JENNER

(*Continued from 938*)

through crisis and cell lines are established, the population ceases to have a single chromosome number, and the median number of chromosomes/cell increases to slightly less than twice the diploid number, that is subtetraploidy. In addition to the loss of diploidy, cell populations cease to reject modified chromosomes on transition to cell lines, and chromosomes appear that are not found in preparations made from primary cells. Metacentric chromosomes, for example, are a common morphological indication of chromosomal abnormality in mouse cells, which normally have only acro and telocentrics.

An increase in chromosome number accompanies establishment and transformation of diploid primary cells because the subtetraploid mode is characteristic of most transformed cell lines[11,28–30]. For example, when normal cells go through crisis to become established lines, they do so with an increase in chromosome number. Also, although transformation of already subtetraploid lines is not accompanied by any change in chromosome number, chromosome number increases when subtetraploid transformed lines are recovered from primary diploid cells after viral infection. Thus, we would have predicted that revertants should have either fewer chromosomes or the same number of chromosomes as transformants. But neither result was found. We report now that a consistent, anomalous increase in chromosome number above subtetraploidy accompanied reversion of spontaneous and virus-transformed cell lines from the malignant transformed phenotype to the growth-controlled normal phenotype, and that subtetraploidy returned with back reversion.

The histogram (Fig. 1) shows the heteroploid spread of 100 selected cells from each cell line, while the median range data (Table 2) give the actual frequency of cells in the median range for each cell line.

Of the four established cell lines, 3T3 had growth control and the other three lines did not. The chromosomes of 3T3, 3T6, SV3T3 and Py3T3 were very similar. All showed a major subtetraploid peak with a minor hyperploid component (Fig. 1*a*, *b*, *d*, *g*).

SV3T3 had the most homogeneous chromosome distribution. 97 per cent of the nuclei scanned at low power fell in the range of the major peak (Table 2). 3T3, 3T6 and Py3T3 had about the same hyperploid component. The subtetraploid peak was still the major chromosome pattern, even in Py3T3, the line with the most hyperploid cells (Table 2). In both transformation of 3T3 and establishment of the low growth control line 3T6, sub-

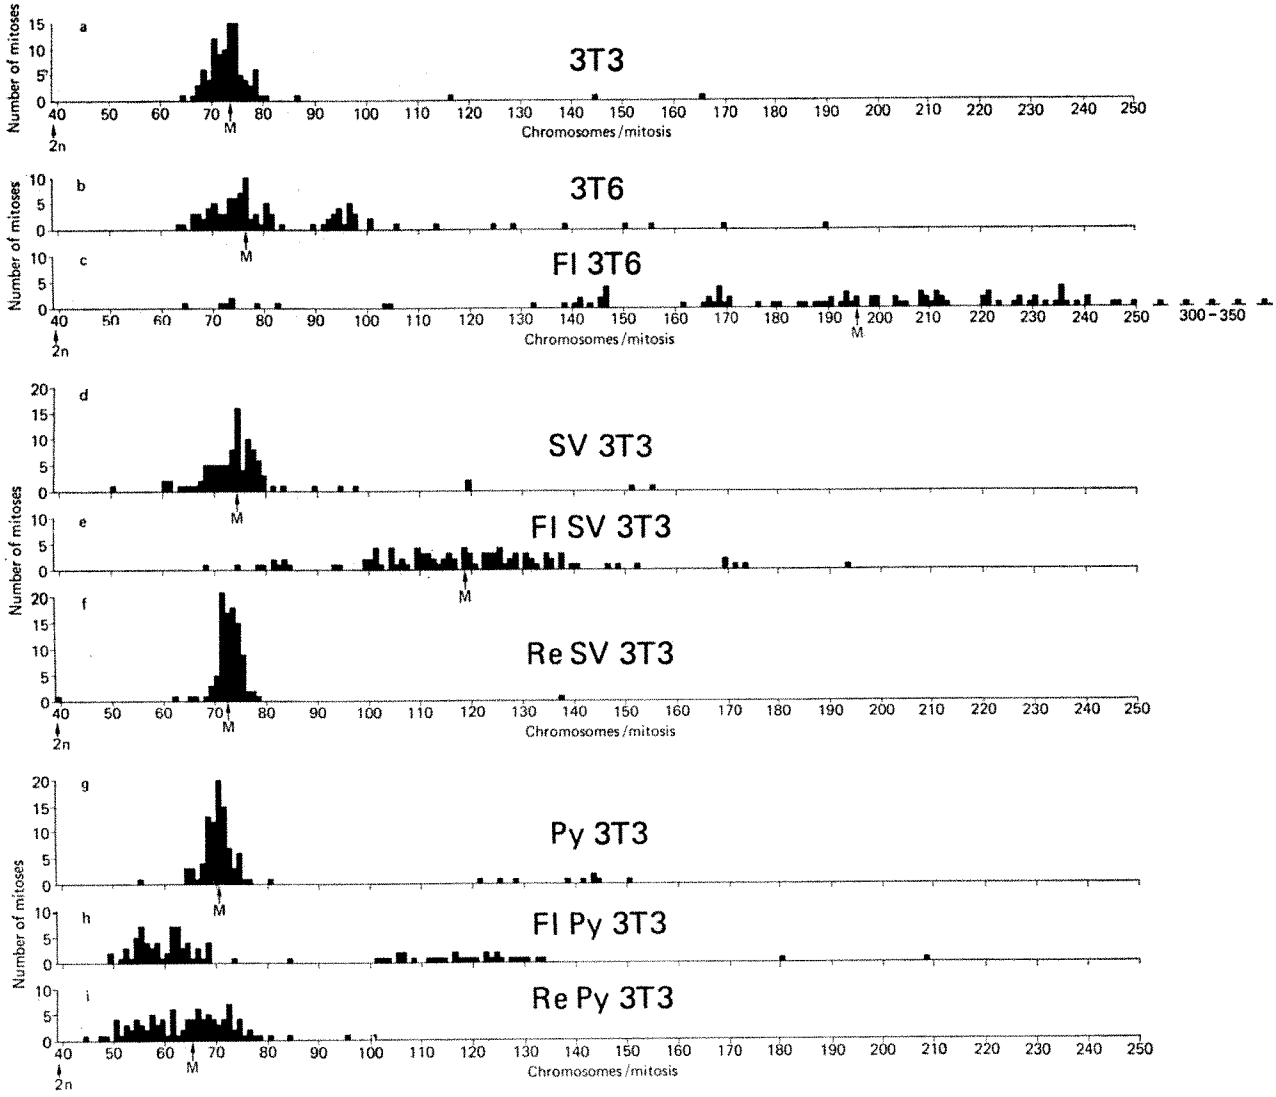


Fig. 1. Histograms of chromosomes/cell against number of cells. For each mouse cell line 100 metaphase preparations were counted at 1,000× magnification. The diploid number (2 n) of the mouse is 40. The median number of chromosomes for each line is indicated (M).

tetraploidy remained the dominant mode as the population lost growth control.

Polyoma and SV40 transformation of primary cells is accompanied by heteroploidy, with the appearance of many abnormal chromosomes[11,30]. 3T3 was, however, already heteroploid and about 11 per cent of 3T3 cells contained metacentrics (Table 2). There were 13 metacentrics per hundred cells for 3T3, 19 for 3T6, 32 for SV3T3, and 10 for Py3T3 (Table 2). Thus, no consistent increase in metacentrics accompanied transformation in these cell lines.

The median chromosome number of 3T6 went from 76 to 195 on selection of variant F13T6 cells. 10 per cent of the F13T6 cells had more than 240 (=12 n) chromosomes. One cell of the 100 counted exactly had 340 chromosomes (~17 n). The overlap of distributions between 3T6 and F13T6 was slight: 10 per cent of 3T6 cells had more than 100 chromosomes, and 8 per cent of F13T6 cells had fewer than 100 chromosomes (Fig. 1*b*, *c*). As expected, F13T6 cells are bigger than 3T6 cells.

The fraction of cells lacking metacentrics declined slightly, from 84 per cent to 63 per cent, but the majority of F13T6 cells still lacked metacentrics (Table 2), and the total number increased slightly, from 19 to 46/100 cells.

The subtetraploid 3T6 population, once committed to the state of low growth control as a cell line, reverted to a state of high growth control (F13T6) with massive additional hyperploidy. This was unexpected, because 3T3, a subtetraploid cell line with growth control, was obtained with no more hyperploidy than the dense cell line 3T6 (Fig. 1*a*, *b*) by selection from the diploid population before establishment.

Revertants selected from the two virus transformed 3T3 lines also had a marked increase in chromosome number and in addition an increased number of metacentrics per cell. The median chromosome number of SV3T3 increased from 75 to 118 with reversion. The F1SV3T3 population had a much broader histogram than SV3T3 (Fig. 1*d*, *e*), but overlap between F1SV3T3 and SV3T3 chromosome number was limited: 6 per cent of SV3T3 cells had more than 90 chromosomes, and 10 per cent of F1SV3T3 had fewer than 90 chromosomes. Five per cent of F1SV3T3 cells counted had more than 160 (=8 n) chromosomes. In contrast to 3T6 and F13T6, F1SV3T3 had many more metacentrics/100 cells than SV3T3 (196 vs 32, Table 2). Only 9 per cent of F1SV3T3 cells were free of metacentrics, as compared with 74 per cent of SV3T3 cells (Table 2).

F1Py3T3, selected from Py3T3, did not shift entirely to higher chromosome number. F1Py3T3 showed a bimodal distribution of counted chromosomes/cell (Fig. 1*g*, *h*). Low power scans showed that F1Py3T3 cells were evenly distributed between the two ranges (median =60,120). No overlap occurred between the two peaks (Fig. 1*g*, *h*). The higher peak is very near to the peak of F1SV3T3. The lower peak clearly is not identical to the major peak of Py3T3; it is about half the higher peak.

Metacentric abnormal chromosomes increased most strikingly in the selection of F1Py3T3 from Py3T3. The percentage of cells with metacentrics increased from 4 per cent to 91 per cent. The number of metacentrics/100 cells went up almost forty-fold, from 10 to 353 (Table 2).

The absolute number of metacentrics/100 cells increased in all three flat revertants. In the two virus-transformed revertants, the ratio of metacentrics to total chromosomes increased in addition (Table 2), whereas in F13T6 the increase in metacentrics just paralleled the increase in total chromosomes per 100 cells.

Both F1SV3T3 and F1Py3T3 grew as rapidly in sparse culture as their parent lines, and both flat lines contained viral T-antigen (Table 2). Thus, the increase in chromosome number accompanying flat reversion did not eliminate the entire viral genome, and did not produce slow-growing lines.

Table 1. ORIGIN AND PROPERTIES OF MOUSE CELL CULTURES

Cell	Growth control	Established line	Transforming virus: Name	Transforming virus: T-ag	Original selection: From	Original selection: By
MEF	+	No	None	None	—	—
3T3	+	Yes	None	None	MEF	—
3T3	−	Yes	None	None	MEF	—
F13T6	+	Yes	—	None	3T6	FUdR
SV3T3	−	Yes	SV40	SV40	3T3	Focus
F1SV3T3	+	Yes	—	SV40	SV3T3	FUdR
ReSV3T3	−	Yes	—	SV40	F1SV3T3	Focus
Py3T3	−	Yes	Polyoma	Polyoma	3T3	Focus
F1Py3T3	+	Yes	—	Polyoma	Py3T3	FUdR
RePy3T3	−	Yes	—	Not done	F1Py3T3	Focus

Some years ago[4] two permanent cell lines were established from mouse embryo fibroblasts. One line, 3T3, retained maximal growth control, while the other, 3T6, did not. 3T3 was transformed by SV40 and by polyoma in 1963 (ref. 31). Transformed sublines were isolated and cloned twice. These lines were stored in liquid nitrogen. 3T3, 3T6, SV3T3 and Py3T3 were thawed and cloned twice in 1967 (ref. 13). They have been kept in culture since. Phenotypic revertants, designed as flat cell lines (F1) because of their low saturation density and their large, flat morphology in culture, were isolated by FUdR negative selection from 3T6, giving F13T6, and from the two virus transformed 3T3 lines, giving F1Py3T3 and F1SV3T3 (ref. 13). Recent spontaneously arising sublines with low growth control were isolated as dense foci from monolayers of F1Py3T3 and F1SV3T3. These were cloned twice and are designated in these experiments as RePy3T3 and ReSV3T3. All cell lines were maintained at 36·5° C in 20 cm² plastic Petri dishes (Falcon) in Dulbecco and Vogt's modification of Eagle's medium supplemented with 10 per cent calf serum. The medium was changed twice daily. Growth control was assayed as saturation density. (+)=Saturation density less than 8×10^4 cell/cm² with 2 changes/week of DME+10 per cent CS. (−)=Saturation density more than 5×10^5 cell/cm² with 2 changes/week of DME+10 per cent CS.

Table 2. CHROMOSOME CONSTITUTION OF MOUSE CELL CULTURES

Cell	Chromosome number: Median/cell	Chromosome number: Median range, fraction	Metacentrics (abnormal): Number of cells with metacentric chromosomes: 0	1	2	3	⩾4	Counted metacentrics/100 cells
MEF	40 (=2 n)	1·0	100	0	0	0	0	0
3T3	73	0·85	89	9	2	0	0	13
3T6	76	0·72	84	13	3	0	0	19
F13T6	195	0·58	63	29	7	1	0	46
SV3T3	74	0·97	74	21	4	1	0	32
F1SV3T3	118	0·95	9	32	28	22	9	196
ReSV3T3	72	0·90	91	6	2	0	1	14
Py3T3	70	0·74	91	8	1	0	0	10
F1Py3T3	60,120	0·50, 0·50	4	18	16	17	45	353
RePy3T3	65	0·79	69	8	4	4	15	115

For preparation of chromosome spreads, a cell line was inoculated at about one-tenth of its saturation density, to give a dividing population. Medium was changed one day after transfer. On the second day, cells were exposed to 0·1 μg/ml. Velban (Vinca Leucoblastine, Lilly) for 4 h, suspended in 0·25 per cent trypsin for 10 min, centrifuged at 900 r.p.m. for 10 min, resuspended, swelled by exposure to 20 per cent foetal calf serum in distilled H_2O for 30 min, recentrifuged at 500 r.p.m. for 10 min, fixed for 30 min at 4° C in cold Carnoy's fixative, air-dried on slides, and stained with 1 per cent acetic acid–orcein. A histogram for each cell line was obtained from exactly 100 well-spread metaphases. In addition about 1,000 cells were examined under low power (100×) and classified according to whether or not their number was in the median class for that cell line. This was done to eliminate the bias against counting cells with higher chromosome numbers, where inadequate spreading and multiple overlaps made accurate counts difficult. The metaphase preparations that were counted exactly for total chromosome number were also counted for metacentrics. Because few unstable configurations of the sort that might interfere with mitosis (dicentrics, rings) were present, it is safe to assume that most of the cells examined were capable of further division and representative of the population.

Back Revertants of T-antigen Positive Flat Lines

A few dense foci inevitably arose in cultures of F1Py3T3 and F1SV3T3 kept at saturation for more than a week. These foci were cloned to provide stable populations with saturation densities of more than 5×10^5 cells/cm². The back revertant lines derived from the flat revertants were called ReSV3T3 and RePy3T3. The back revertant of F1SV3T3, like F1SV3T3, remained positive for SV40 T-antigen. Neither back revertant line was selected by re-infection with a transforming virus; both arose spontaneously.

Chromosomes in RePy3T3 and ReSV3T3 returned in both cases to distributions close to those of the respective dense transformed parent lines SV3T3 and Py3T3 (Fig. 1*f*, *i*). The SV40 transformed series shows this most clearly (Fig. 1*d*, *e*, *f*). Only about 2 per cent of the F1SV3T3 cells are in the median range of SV3T3. Presumably a cell of this minority was the ancestor of the ReSV3T3 population.

In the polyoma transformed series, RePy3T3 lost the hyperploid peak but did not return to the distribution of Py3T3. Apparently, RePy3T3 arose from one of the low mode cells of F1Py3T3 (Fig. 1*g*, *h*, *i*).

The back revertant populations lost metacentrics also, to return to the range of their transformed parents. A

few hyperploid cells contained most of the metacentrics in RePy3T3 (Table 2).

These data show that increase in chromosome number accompanies reversion, and decrease in chromosome number accompanies back reversion. The cell lines studied here were selected as discrete variants in at most two selective steps. Yet in each case the revertant population had a hyperploid chromosome distribution that overlapped only slightly with the parental distribution. Selection in each case was exerted on growth control, yet in each case the chromosome constitution was markedly changed. We conclude, therefore, that increase in chromosome number is a necessary part of the mechanism for maintenance of the reverted state of these cell lines.

Is hyperploidy sufficient, as well as necessary, to maintain the revertant state in flat cells? Hyperploid cells are larger than their transformed parents; they therefore have a lower surface/volume ratio. This renders them less susceptible to the stressful loss of synthesized metabolites to the medium[1,28,32,33,35]. This may be the factor behind the induction of hyperploid revertants by culture at low cell density. Such revertants are very unstable, as they grow to form visible colonies[34]. Many back revertants arise after only 10 cell divisions, an instability much greater than the frequency of re-reversion of the flat revertants selected for by passage in FUdR.

An origin consistent with the transient nature of those revertants would be that the cells first became hyperploid in response to the stressful conditions of high cell dilution, and that polyploidy resulted in reversion. Once the cell number had increased enough to permit the cells to condition the medium, hyperploidy would no longer be selective, and any cell with the standard subtetraploid complement of a back revertant would be able rapidly to overgrow the culture.

If one can select for reversion by requiring polyploidy or select for polyploidy by requiring reversion, then any mechanism for maintenance of the reverted state should require hyperploidy as a necessary step. At present the mechanism of maintaining reversion is largely unknown, as is the mechanism for maintaining transformation. Recent findings seem to indicate that the maintenance of the transformed state in viral and spontaneous transformation is mediated through alterations in the glycoproteins of the cell surface. Correspondingly, flat cells complete the normal surface, and are unagglutinable[23,24]. These alterations, assayed with plant agglutinins, are detected as an increase in agglutinability of cells accompanying a loss of growth control[36–41]. Increases in agglutinability occur as well in cells lytically infected with SV40 as polyoma[19,42].

Two mutants of polyoma virus have recently been described of genes which affect the maintenance of the transformed state through interference with cell surface. One is a host range mutant that cannot grow on 3T3, but that can grow on polyoma-transformed 3T3[20]. This mutant cannot transform either rat or hamster cells, and is unable to induce an increase of agglutinability in lytic infection of mouse cells[19]. The other transformation mutant is temperature-sensitive. When BHK hamster cells are transformed with this mutant and kept at low temperature, they resemble other transformants and are agglutinable. When transformed cells are shifted from low to high temperature, they regain orientation and lose agglutinability[21].

The agglutinins apparently detect a cell surface structure responsible for maintenance of growth control, and a polyoma gene can affect this structure. The surface structure detected with agglutinins on transformed cells, however, cannot itself be a viral gene product, because (*a*) spontaneous, chemical, and X-ray induced transformants from 3T3 and BHK, as well as tumour cells of spontaneous origin, agglutinate as well as viral transformants[36,37,39]; (*b*) brief treatment with very low concentrations of proteolytic enzyme can bring about a change in the cell surface similar to that occurring in the transformation of normal to malignant cells[38]; (*c*) the SV40-induced surface antigen (S-antigen) is apparently a component of the normal cells, since cell lines transformed spontaneously or by polyoma virus and non-transformed lines can be made to display SV40 S-antigen by mild proteolytic digestion of their cell surfaces[42]; and (*d*) a transient loss of growth control resembling transformation can be induced directly in a 3T3 population by the addition of small amounts of trypsin to the confluent culture[43].

Because our flat revertants are unagglutinable, hyperploidy must in some way act to permit the revertant cell to mask agglutinin receptor sites, thereby reconstructing a normal cell surface. Increase in cell size alone thus is not the cause of reversion.

What role does the increase in metacentrics have in reversion from viral transformation that is not required for reversion from non-viral transformation? A virus-transformed cell may revert with chromosome loss, eliminating all viral genes[15,22], or with chromosome gain, despite the continued presence of the viral genome. Translocation, with chromosome gain, may be a way for virus-transformed cells to revert by inactivating[1,15,21,28,44] viral gene products responsible for maintenance of transformation, rather than by losing[15,21] the entire viral genome. Whatever the mechanism, inactivation of some but not all viral gene products must occur in revertants, since they contain T-antigen, but are growth controlled. Only the gene products necessary for the cell surface alteration and the maintenance of the transformed state would need to be inactivated, so the virus-specific T-antigen should have no part in maintenance of the transformed state (Table 1).

Does the relation of hyperploidy to reversion predict the behaviour of hybrids between malignant and non-malignant cell lines? All viable mouse × mouse hybrids are, in a chromosomal sense, revertants: both types of cell lines contain more mouse chromosomes than any typical established mouse cell line. Recent reports show that hyperploidy of mouse chromosomes accompanies growth control in hybrids. When mouse × mouse hybrid lines were prepared[47] between 3T3 ($M = 70$) and a spontaneous mouse tumour line with little growth control ($M = 53$), the hybrids had between 100 and 120 chromosomes and were as growth controlled as 3T3. With time in culture, chromosomes were lost and growth control of the hybrid population dropped, variants with higher saturation density appearing.

Two hybrid lines[47] were isolated from mixtures of SV40-transformed human cells ($M = 71$), and 3T3 mouse cells ($M = 70$) contained the SV40 T-antigen (and presumably the SV40 genome), but both hybrids were as growth controlled as the 3T3 parent. Both hybrids had 15 human and 135 mouse chromosomes. This increase in mouse chromosomes (70 to 135/cell) is very similar to the increase seen in the F1SV3T3, which are also growth controlled despite the presence of the SV40-T-antigen. If the generalization is accepted that malignancy *in vivo* and growth control *in vitro* are causally related[1,3,8–10,12], then an *in vivo* study is consistent with the hypothesis that hyperploidy is related to reversion. Malignancy was suppressed when malignant and non-malignant cells were fused[48] to give rise to viable hybrids with between 85 and 128 mouse chromosomes/cell. These hybrid lines gave rise to spontaneous malignant re-revertants with fewer chromosomes.

Is Reversion of Clinical Interest?

The most significant test of this hypothesis would be by inversion, determining whether agents causing hyperploidy (for example, low concentrations of velban or DNA base analogues) revert transformed and malignant populations. Recent observations on the suppression of

malignancy in melanotic melanoma cells with subtoxic levels of BUdR may be relevant here[49]. BUdR damages chromosomes[50] and induces hyperploidy[52]. BUdR-treated melanoma cells revert, lose pigment and become growth controlled. Revertant cell nuclei are at least twice the diameter of nuclei of the melanoma cells (ref. 49, Fig. 5). It would be interesting to see whether these "suppressed" cells are also hyperploid.

Selective killing of cancer cells by agents that interfere with cell division has been the rationale of most chemotherapy of tumours. X-irradiation, imuran, cytoxan, vincaleukoblastine, amethopterin, dactinomycin and nitrogen mustard are all effective against leukaemias and solid tumours because they are preferentially toxic to dividing cells[52]. Chemotherapy is, however, rarely a complete success. Remission is often followed by relapse, with the reappearance of tumour cells, especially in the leukaemias. Non-proliferative leukaemia cells have been implicated as the source of regrowth in relapse[53,54].

If it is true *in vivo* as well as *in vitro* that hyperploid variants can be more growth controlled than their parents then these drugs and others used for cancer chemotherapy must be assayed for the possible induction of hyperploidy in the tumour cells that they do not actually kill. Should revertant hyperploid cells be induced, they would then (as non-dividing cells) be resistant to further doses of the drug, and re-revertants would be able to grow out from them once the drug was removed.

BUdR[49], FUdR[13], dactinomycin[55], X-rays[56], and colcimide[1] have already been shown to induce polyploidy in cells surviving low doses. Therefore these agents must be suspected of inducing revertant hyperploid cells *in vivo*. Such revertants would be non-proliferative cells from which relapsing tumours might grow out, by back reversion.

This research was supported by grants from the American Cancer Society and the US National Institutes of Health. Field Control of Plant Growth and Development through the Laser Activation of Phytochrome

by

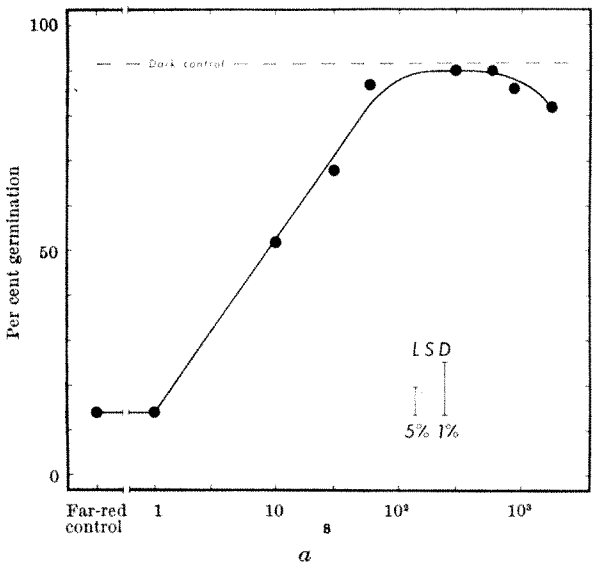
Helium–neon lasers emitting at 632·8 nm can influence the phytochrome controlled growth and development of plants more than a quarter of a mile away. It may therefore be possible to control the growth of crops using lasers to activate the phytochrome system.

THE action spectrum and photoreversible nature of the phytochrome system were first described by Borthwick *et al.*[1,2]. It is now known that this photoreceptor occurs throughout the plant kingdom, and that its activation, which can be brought about by low energies and/or brief periods of illumination, affects several aspects of plant growth. Although this means that control of some phases of development is theoretically possible, little attempt has been made to explore the practical implications of this discovery in the field.

In 1966 we reported an experiment in which floodlamps were used nightly to interrupt the dark period of a field-



grown crop of barley[3]. The results of that work, which demonstrated that the period to field maturity could be significantly shortened (in one variety by up to three to four weeks), prompted a search for new light sources which might be capable of activating the phytochrome response system.

This communication deals with an examination of the effects of a helium–neon gas laser (emitting continuous light at a wavelength of 632·8 nm) on the induction of photomorphogenesis in several different plant response systems. The ability of the laser to activate phytochrome responses was first explored in laboratory experiments and then examined in field experiments at distances of about one-quarter mile.

Laboratory Experiments

The initial aim of this work was to demonstrate that a helium–neon laser could activate phytochrome initiated responses. The beam from a Spectra-Physics model 115 laser (rated single mode output of 3 mW), the first laser used in these experiments, was passed through a Wratten No. 22 gelatine filter to eliminate emission in the blue region of the spectrum. It was then diverged with a 6·3 cm focal length lens 25 cm from the laser port, and deflected 90° by a front surfaced mirror 40 cm from the lens. All the plant tissue was thus irradiated from above (about 18 to 26 cm below the mirror).

The intensity at the surface of the tissue was measured with a Spectra-Physics power meter and varied from 0·1–0·15 mW/cm². The diameter of the effective area was about 2·5 cm and all manipulations were carried out under green safe-light provided by an Ilford bright green filter No. 909.

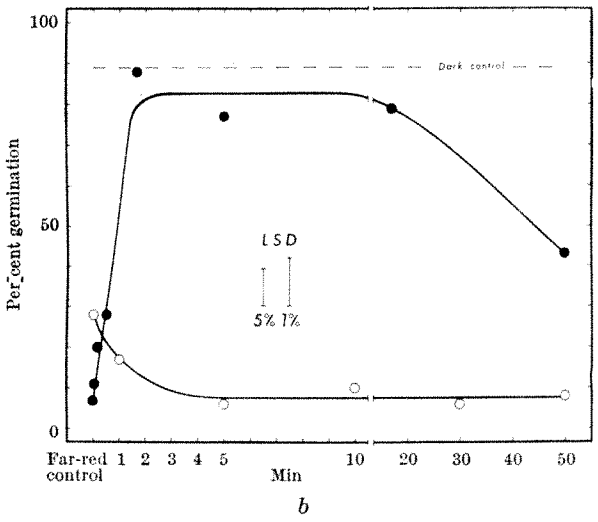


Fig. 1. Laser-induced promotion of lettuce seed germination. *a*, 1967 Great Lakes lettuce seed, fifty seeds per 5 cm Petri dish on two Whatman No. 1 filter papers and 1 ml. H_2O, exposed to far-red light (incandescent filtered through Westlake FRF-700 filter) for 36 h at 25° C. Seed then irradiated with laser for varying periods; germination measured 24 h after start of irradiation. *b*, Same seed irradiated in the same way the following year. Open circles: seed irradiated for 30 s with laser and then for indicated periods of time with far-red light to reverse effects of laser stimulation. Three replicates of fifty seed each were used for each treatment in both experiments.

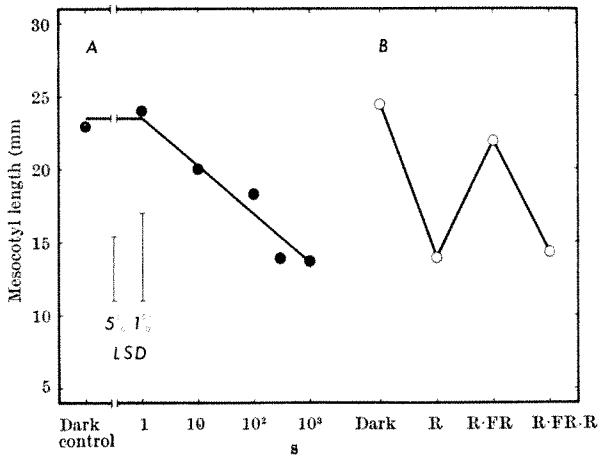

Fig. 2. Inhibition of oat mesocotyl elongation by laser irradiation. *A*, Effect of increasing exposure to laser irradiation on mesocotyl elongation; *B*, reversibility of laser-induced inhibition by successive irradiations of 5 min laser and 5 min far-red. *Avena sativa* cv. Swan dehusked seed germinated in dark at 25° C for 41 h in 9 cm Petri dishes containing two Whatman No. 1 filter papers and 4 ml. H_2O. Uniformly germinated seeds were transferred to waxed paper cups containing a central plastic 2 cm diameter, 3 cm high platform covered with 1–11 cm Whatman No. 1 filter paper moistened with 7 ml. H_2O. Ten seeds were placed on each platform, embryos facing outwards, with primary roots in contact with the filter paper. All embryos were exposed simultaneously to the laser irradiation which started at 43 h and ended at 46 h after the start of inhibition. The cups were covered with 7 cm Petri dish lids and the seedlings subsequently grew in darkness at 25° C for 4 days. Each treatment consisted of three replicates of ten seeds.

One of the most commonly examined phytochrome controlled responses is the red light activation of lettuce seed germination. In this test, the response of lettuce seed from a single harvest was examined in successive years (Fig. 1). In the year of harvest (Fig. 1*a*), 10 s irradiation with the laser was sufficient to cause a highly significant stimulation of germination, though 1 s had no effect at all. The response was maximal after 1 min of exposure and it seemed that 30 min of irradiation resulted in a decreased germination percentage.

When the experiment was repeated the following year, the responsiveness of the seeds to short irradiations had decreased although the overall nature of the response was the same (Fig. 1*b*). In this case, though the effect of 1 and 3 s of exposure was significant, it was appreciably less than in the previous year. The response reached a maximum at about 100 s and after 1,000 s there was significant inhibition (Fig. 1*b*). Moreover, the stimulation produced by 30 s irradiation with the laser was significantly reversed by exposure to far-red light for 1 min or longer.

A different kind of phytochrome controlled response is stem elongation, which involves changing the rates of tissue growth. The ability of the helium–neon laser to prevent mesocotyl elongation in rapidly growing seedlings is illustrated in Fig. 2. Irradiation for 1 s did not inhibit mesocotyl elongation, though increasing lengths of exposure produced an essentially linear response. Further, a demonstration of the reversibility of the response is included (Fig. 2*B*) which indicates that the response can

be repeatedly reversed by alternating exposures to the laser and far-red light.

The last physiological response tested in the laboratory differed from the dormancy breaking and growth altering effects examined above. This test involved the determination of the capacity of the laser to alter morphological development by inhibiting the long night induction of flowering of Japanese morning glories (*Pharbitis nil Chois.* var. Violet).

At the time of irradiation with the laser, each cotyledon was about 3 cm long from base to lobe tip. Because the beam was not large enough simultaneously to encompass both cotyledons, they were fastened together and the base of each was exposed. During the 1,000 s irradiation, however, the lobes were also occasionally exposed to the beam.

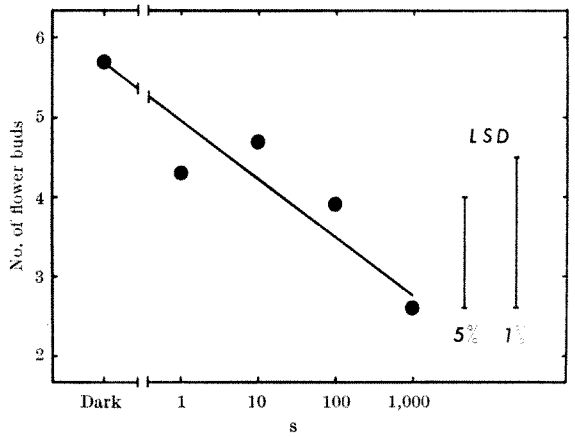

Fig. 3. Laser-induced inhibition of flowering of *Pharbitis nil. Chois.* Seed acid treated and washed[4] and planted in waxed cups with 'Perlite'. Seedlings grown at 27° C under 24 h fluorescent illumination and watered daily with half strength Hoagland's solution. After 7 days seedlings transferred to dark and irradiation started in the middle of the long (16 h) imposed night. (Treatments finished 3 h later, so were close to, but not quite in, the middle of the dark period.) At the end of the dark period the seedlings were transplanted into compost-filled clay pots, watered daily and grown at 27° C in 16 h fluorescent light (1,700 foot candles) for 20 days. Each treatment contained seven replicates and axillary and terminal buds were examined with a magnifying lens.

Fig. 3 shows the linear decrease in the number of flower buds formed as a result of increasing exposure to the laser. This response seemed to be more sensitive than the previous ones tested although the results were rather variable. But four of the seven plants which received the long night treatment formed terminal flower buds whereas none of those which were irradiated for 1 s or longer did so. Although *Pharbitis* seemed to respond to 1 s of irradiation, the maximum effect was not achieved by 1,000 s of exposure.

Field Experiments

The results of the laboratory experiments indicated clearly that a helium–neon laser could activate the phytochrome system, and encouraged us to attempt to reproduce the effects at greater distances. In these experiments a different laser was supplied by the Laser Development Group of the Weapons Research Establishment, Salisbury, South Australia. It was not a commercial unit and delivered a total multimodal output of 8 mW. The laser was placed at a window on the third floor of the Waite Institute and, because the ground slopes away from the building, the height of the laser and its angle of inclination both altered between experiments. Because the blue emission which accompanies the red is not projected in a parallel beam, we did not filter it out in the field experiments.

Pharbitis was chosen for the experiments on inhibition of flowering, because this response is more sensitive in *Pharbitis* than in the other species investigated. In the first experiment the *Pharbitis* seedlings were placed at a distance of 170 feet and the angle of laser inclination was 15°. The spot size was 15 cm and intensity (as measured with the Spectra-Physics power meter) averaged about 0·1 mW/cm². Only one treatment was imposed and the results (Table 1) indicated that exposure of the seedlings for 1,000 s was sufficient to activate the phytochrome and inhibit flowering.

Table 1. EFFECT OF NIGHT BREAK ON FLOWERING OF *Pharbitis*

Treatment	No. of flowers induced on 28 *Pharbitis* plants
Control—16 h night	38
1,000 s night interruption	2

Pharbitis seed acid treated and washed[4] and planted in moistened vermiculite for 48 h. Seedlings transplanted to 2·5×5·0 cm vials containing half strength Hoagland's solution for 2 days and grown under 24 h fluorescent irradiation (1,700 foot candles) at 27° C. Seedlings supported by 2·5 cm square of plastic foam in vial mouth. Vials placed into circular wooden racks placed, in turn, into enamelled pots which were covered at the start of the long inductive night. The pots were taken to the irradiation site and each rack was exposed as a unit to the laser beam. At the end of the dark period, the seedlings were transplanted to 13 cm compost-filled pots (two per pot) and grown for two weeks at 27° C in a 16 h, 1,700 foot candles fluorescent day.

The experiment was repeated at a distance of about a quarter mile (1,230 feet), and with a laser angle of inclination of 2·5°. To achieve this distance a collimating lens was attached to the laser, producing a spot size of about 15 cm; maximum intensity was 0·15 mW/cm². With a more extensive range of treatments (each of two replicates of ten plants), results (Fig. 4) very similar to those obtained in the laboratory experiment with *Pharbitis* (Fig. 3) were obtained. A linear relationship between length of exposure and inhibition of flower bud formation was found, so distance is not a factor in the effectiveness of laser illumination provided that the beam does not diverge too much.

The last experiment, with barley, was not really a field experiment but is included in this section for convenience. We used the same laser as was used in the field experiments, although it was placed only 60 feet from the plants. The laser beam was focused through a 10 cm focal length lens at 40 cm from the plants, and spot size at the plant position was 12 cm. Because the laser and the plants were at the same level, there was zero angle of inclination of the incident irradiation, and intensity was 0·20 mW/cm².

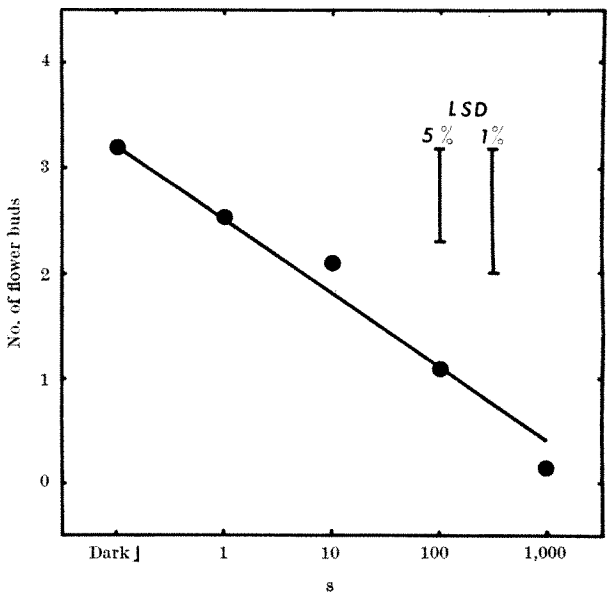

Fig. 4. Inhibition of flowering of *Pharbitis nil. Chois.* induced by laser illumination at a distance of 1,230 feet. Seed acid treated and washed[4] and planted in vermiculite for 48 h. Seedlings transplanted and grown in 2·5×5 cm vials containing small plastic foam supports and half strength Hoagland's solution for 2 days under continuous fluorescent light at 27° C. Ten vials, in circular wooden racks inside covered enamelled pots, taken to irradiation site and exposed as a replicate to the laser beam. At the end of the dark period the seedlings were transplanted into compost-containing pots and grown for 2 weeks at 27° C in a 16 h fluorescent day (1,700 foot candles).

Table 2. EFFECT OF NIGHT BREAK ON BARLEY DEVELOPMENT

	Mean stage of development		
	One exposure	Two exposures	Three exposures
Control	2·2	2·6	2·6
10 s	3·3	2·6	3·1
100 s	2·7	2·9	3·0
1,000 s	2·8	3·1	4·0

Least significant difference ($P = 0.05$) = 0·7.

Barley seed was germinated in 9 cm Petri dishes with two Whatman No. 1 filter papers and 4 ml. H_2O at 20° for 24 h. Uniform seedlings were transplanted (five per pot) to Perlite-filled pots and watered daily with half strength Hoagland's solution. Plants were grown at 23° C in a 12 h fluorescent-incandescent daylength (1,700 foot candles) for 21 days. At the time of irradiation the pots were removed from the constant environment cabinet, irradiated, and then replaced in the same environment. Identical procedures were followed on successive nights for treatments requiring two and three exposures. At harvest, 8 days after the initial irradiation, the plants were dissected and the stage of development[5] of the apex was recorded. Each value is the mean of ten replicates.

Barley is not notably responsive to a few cycles of night interruption. But because floodlights had affected the growth and development of several varieties[3], it was of interest to compare the effects of the laser with the earlier results. *Hordeum distichum* cv. C15611 was chosen because it was more sensitive than the varieties tested before. The results of this experiment (Table 2) demonstrate that, in spite of the fact that the laser output energy level was just over the threshold for Wintex barley[6], significant stimulation of apical development was produced in just eight days. The fact that significant effects were produced by three night interruptions illustrates that in some cases successive nightly irradiations at low intensity levels have significantly greater effect than a single exposure of greater length or higher intensity.

Energy Relationships in the Laser Activation of Phytochrome

The effective use of laser energy in the control of crop plant growth and development will depend on several aspects of both the response and the laser. Energy requirements for phytochrome activation of different crops differ markedly. The results of the present work substantiate previous results which indicate not only that there is a large energy difference between the lower threshold response level and the response saturation level, but that a particular process, as in barley, can be influenced both by the intensity and by the number of exposures. The absolute energy required to produce a response with the laser is very close to that required with other light sources. In 1952, Borthwick *et al.*[1] determined the incident energy requirement for the promotion of lettuce seed germination (Grand Rapids). A two-prism spectrograph with 35 Å/cm dispersion at 600·0 nm and a slit width of about 9·0 nm, $2{\cdot}11 \times 10^{-3}$ J/cm² of incident energy between 653·0 and 663·5 nm produced 50 per cent germination. An estimate of the energy required to reach this level of germination at a wavelength of about 632·8 nm was made from their graph and is $4{\cdot}5 \times 10^{-3}$ J/cm². This agrees well with our results. Assuming an incident energy from the laser at the seed surface of 0·25 mW/cm², Fig. 1*a* indicates that the incident energy requirement for 50 per cent germination (achieved with a 10 s irradiation) was $2{\cdot}5 \times 10^{-3}$ J/cm². Because of the ageing of the seed and their lowered sensitivity, the energy required for 50 per cent germination in the experiment illustrated by Fig. 1*b* was greater by a factor of five, that is, $12{\cdot}5 \times 10^{-3}$ J/cm². Similar results were obtained from a comparison of energy requirements reported for barley[6] and those found in this work.

Specific Advantages of Lasers

There are several possible reasons for using lasers in agricultural or plant physiological investigations: (1) the spectral purity of the emitted light may be important in studies dealing with specific photoreceptors[7]; (2) the intensities possible at specific wavelengths are frequently greater than can be obtained with other sources of monochromatic light; (3) the small cross-section of the beam may be valuable for producing highly localized intracellular injuries, or (4) for intracellular localization of specific photoreceptors.

In this work, the underlying aim was to determine whether a laser emission of 632·8 nm could activate the phytochrome system, and, if so, whether it was possible to produce phytochrome responses at large distances. So here, the important characteristic of laser light is that it is not subject to the inverse square law (that is, intensity does not decrease inversely as the square of the distance). (Laser beam intensity diminishes because of beam divergence, or absorption by or reflexion from intervening matter.) Also, though other sources of light may be more efficient than at least some lasers in the conversion of electrical into light energy, the proportion of energy produced at phytochrome-activating wavelengths is extremely small. With helium–neon lasers, all the emitted light is of the desired wavelength.

Laser Control of Crop Growth and Development

The experiments reported here demonstrate that helium–neon laser light can activate the red photoreceptor of the phytochrome system in plants, and that effects can be seen at distances of one-quarter mile and perhaps more. In practical terms, this means that the photoperiodic responses of crops are potentially controllable with lasers.

The clearest and perhaps only present example of photoperiodic control of field crop growth is with the chrysanthemum[8]. In the western United States chrysanthemums are grown outdoors under incandescent lights to interrupt the night period and control the reproductive behaviour of the plants. Here, as with our Japanese morning glories, flowering is inhibited by the activation of the phytochrome system during the night. The results obtained with barley in this work and earlier[3], and with other crops such as pineapple, however, illustrate that a phytochrome-activating night break can also be effective in stimulating the initiation and development of reproductive growth. Photoperiodic experiments with other types of plant have indicated that vegetative growth, as well as reproductive growth and development, can be influenced[9].

The lasers used in this work were not particularly powerful in comparison with those already available commercially. Reciprocity experiments[10] have indicated that time of exposure can be compensated for by intensity so that, for example, the minimum effective exposure for Japanese morning glories will be reduced to 0·1 s with a laser that has a power output ten times greater than the one used. Unfortunately, however, little information is yet available on the energy requirements of the phytochrome system of most crop plants, or of the sorts of useful responses that can be induced. As these kinds of data accumulate and as laser technology develops, the potential for laser-mediated control of the growth and development of crops may be exploited.

We thank Mr Thonemann and Mr Pyle of the Weapons Research Establishment, and Dr Murray of the Flinders University for their help and generosity.

The volcanic layer may be only 200 m thick at 45° N and oxidation of titanomagnetite may be responsible for the decrease in amplitude of the magnetic anomalies away from the ridge axis.

THE parameters measured in palaeomagnetic work are total intensity, declination and inclination. These define the natural remanent magnetization (NRM) of rock samples. In this article we summarize our observations of intensity and inclination (but not declination) of basalts collected from the Mid-Atlantic Ridge at 45° N and describe their opaque minerals. Detailed accounts will be given elsewhere and some have already appeared[1-3].

At 45° N the Mid-Atlantic Ridge[4] has a median valley about 9 km in width whose floor is at an average depth of 2,900 m. Between 45° N and 46° N the valley lies in a direction 19° E of N. The valley has deep depressions and ridges elongated in the direction of the valley. It is possible to draw a line defining the topographic axial depression (called the axis) of the ridge to an accuracy of 1 or 2 km. The crest mountains on either side of the median valley have an average width of 50 km, and the peaks are commonly 1,800 m above the median valley. The high fractured plateaux form the flanks of the ridge. Photographs show the exposed hard rocks to be mostly pillow basalts; samples from the median valley are very fresh, both to the eye and geochemically. Many samples from the crest mountains and high fractured plateaux are entirely weathered and have not been studied. In other samples, visible weathering is confined to the surface, and fresh rock can be cut from their centres. In this way, material, which to the naked eye appears fresh, has been obtained at distances up to 150 km from the axis.

Remanent Intensity

The mean intensity of NRM based on thirty-eight samples is 0·0092 egs units cm^{-3}. The mean susceptibility is $8{\cdot}8 \times 10^{-5}$ so that the magnetization induced by the present field is negligible compared with the NRM. Twelve samples from the high fractured plateau have a mean NRM intensity of 0·0041, but within the median valley the intensities are much higher (mean of nine samples is 0·0574). In samples from the axis itself, the intensity reaches 0·1 (Fig. 1).

The magnetic properties of samples show several striking features. Blocking temperatures (the temperature at which remanence components are destroyed by heating in the laboratory) of less than 300° C are characteristic of most samples from the median valley[1]. The mean blocking temperature of samples from the crest mountains and high fractured plateau is 450° C (see ref. 1). Curie temperatures also increase with distance from the axis[2,3]. Various experiments show that the iron minerals in these basalts are very readily oxidized by heating, resulting in an increase in Curie and blocking temperatures and in saturation magnetization, but a decrease in thermoremanent magnetization.

Under alternating field (AF) demagnetization the directions of magnetization are exceedingly stable, commonly being little changed in 1,000 oersted peak field. The directions in several samples are changed by less than 5° in fields as high as 2,000 oersted. This directional stability is very much higher than that normally encountered in subaerial basalts in which fluctuations in direction commonly set in during AF demagnetization at about 500 oersted[5]. The stability of intensity is also high; the average field required to reduce the intensity by 50 per cent is 320 oersted, whereas values for subaerial basalts are typically about 200 oersted[6].

The saturation isothermal remanent magnetization (IRM_{sat}) ranges from 0·17 to 0·85 cgs. units cm^{-3}. For the high intensity axial basalt the IRM_{sat} is 0·57, so that the ratio NRM/IRM_{sat} is 0·18. This is exceedingly high,

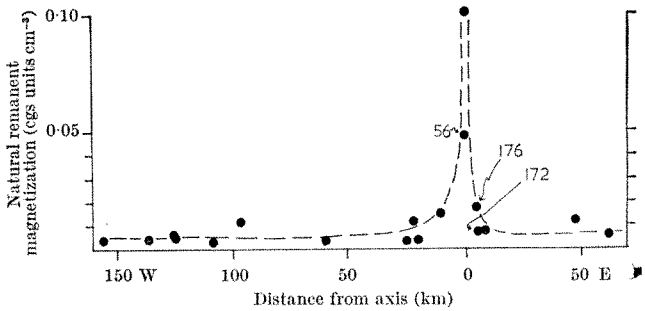

Fig. 1. Graph of natural remanent magnetization against distance from the axis (zero point) of the Mid-Atlantic Ridge at 45° N. The points are averages for dredge and core stations and are each based on results from one to five separate samples. The stations mentioned in the text are indicated.

and shows the natural magnetization process to be a very efficient one indeed. The coercivity of IRM_{sat} averages 430 oersted, which is about 100 oersted higher than that commonly found in subaerial basalts[5].

Inclination Estimates

The original attitude of dredged pillow basalts can sometimes be determined from their form and internal structure so that a rough estimate of inclination is possible[7,8]. Estimates from six pillows dredged at station 56 (45° 13′ N, 28° 0′ W) have a spread of 20° and a mean of +44° (Table 1). The error in determining attitude is probably not more than 20°, and replicate values from the same pillows obtained independently agree to 10°. The polarities are normal.

Table 1. MAGNETIC INCLINATION IN PILLOW BASALTS AT STATION 56

Sample No.	Inclination (°) F.A.	E.I.
1	+38	
2	+39	+32
3	+34	+44
4	+44	
5	+46	
6	+53	

The horizontal is assumed parallel to the equatorial plane of the pillow. These observations were made by us independently.

Table 2. RESULTS FROM BORE CORES 172 AND 176*

Piece	Natural remanent magnetization (cgs units cm^{-3})	Initial inclination I_0 (°)	Inclination after demagnetization in 100 oersted I_{100} (°)
172 (5)	0·0051	−25	−32
176C (1)	0·0081	−24	−27
176B (3)	0·0163	−39	−41
176A (2)	0·0199	+26	+24

* Each core piece has been cut into standard cylinders the number of which is entered in parentheses. The data are averages for cylinders.

Inclination information from the first basalt drill core using the new 'Brooke' drill[9] during the cruise of CSS Hudson (May to July 1969[10]) is summarized in Table 2. The vertical axis of the core may not be defined to better than 20° although it is believed to be much better than this. Core 172 (45° 5·3′ N, 27° 58·4′ W) is a single piece 15 cm long. Core 176 (45° 5·2′ N, 27° 59·3′ W) is in three pieces (A, 8 cm; B, 10 cm; C 4 cm) which do not articulate. After magnetic cleaning in 100 oersted AF the directions within each piece agree to better than 2°. This is the first cored basalt from the crest of an ocean ridge and there are many uncertainties in interpreting the data. It is entirely possible, for instance, that the drill sampled boulders embedded in sediment so that the inclination and polarity results are meaningless. If this is so, then the inclinations at each station would differ widely. There is, however, approximate agreement between cores (mean of 176 is 31°, 172 is 34°). Moreover, positive inclinations decrease and negative inclinations increase after magnetic cleaning as is expected of rock *in situ* (Table 2). Piece 176A has positive inclinations (normal or negative polarity). The rest of core 176 is reversed.

The Earth's field during the past few million years has been accurately that of an axial geocentric dipole when averaged over periods of tens of thousands of years[11], and the expected inclination at 45° N is 63°. The estimates from pillows and core are 20° to 30° lower. The effect is interesting, but the evidence is not unequivocal, and it is too early to speculate as to its cause. Some evidence of low inclinations has also been reported from the Reykjanes ridge[8].

Opaque Minerals

The predominant opaque minerals in these submarine basalts are skeletal titanomagnetite and ilmenite. Sulphide minerals (pyrite, pyrrhotite, marcasite and chalcopyrite), so rare in subaerial basalts, are generally present. Titanomagnetite is responsible for the magnetization, but the ilmenite and sulphides are interesting because the ilmenite is always in the lowest state of oxidation (R1 on an ilmenite oxidation scale R1–R7) and the sulphides indicate a reducing environment during cooling. The size of the titanomagnetite is generally below 1–5 μm (there is sometimes a coarser fraction ranging up to 100 μm) and less than that typical of subaerial flows. Twenty-five of the thirty-four samples studied are in the lowest oxidation category C1 (titanomagnetite oxidation scale C1–C6) and none is in the high grade pseudomorphic oxidation categories (C4–C6). The high temperature deuteric oxidation, so common in subaerial basalts, is subdued or absent. A further remarkable feature of the titanomagnetites is that they have often been partially altered to titanomaghemite. This is a low temperature oxidation effect. It is absent in axial samples.

Axial Intensity

From the general appearance of the basalt pillows and the observations just described it is certain that they cooled very quickly as they were extruded onto the ocean floor. Contact with very cold[12] bottom water (3° C) would cause the almost instantaneous formation of an impervious crust, which, together with the confining pressures of overhead water, would cause the retention of volatiles and sulphides, and the rapid crystallization of skeletal titanomagnetites. The blocking temperatures of the axial rocks are low (less than 300° C) so that it is likely that the titanomagnetites were in their present form when the remanent magnetization was acquired. This situation is one of the most favourable in nature to the formation of thermoremanent magnetization (TRM), that is, the acquisition of remanence by cooling of already formed crystals through their critical blocking temperature[13]. This would explain the high ratio NRM/IRM_{sat}. In contrast subaerial lavas cool over periods of years, lose their volatiles, and may undergo, to varying degrees, subsolidus oxidation at temperatures below the characteristic blocking temperatures[14,15]. Hence their magnetization is, to some extent at least, a chemical remanent magnetization (CRM) formed by grain growth through the critical blocking diameter at temperatures below the Curie temperature[15–18]. Experiments[17] show that TRM is some ten times more intense than CRM for the same material in the same ambient field. We therefore suggest that to a first approximation the very high intensities in these axial submarine basalts is a consequence of their TRM, in contrast to subaerial basalts whose remanence may be partly a CRM and of lower intensity.

Intensity Away from Axis

The next item to consider is the decrease of intensity with distance from the axis, most of which occurs within about 5 km (Fig. 1). In terms of time this means a period of order 10^5 years[19]. There appears to be some physical or chemical process which demagnetizes a rock as it moves sideways from the axial volcanic source. Viscous decay due to thermal agitations is one possibility and occurs as the logarithm of time, but the observed decay is more rapid (Fig. 1). The chemical demagnetization processes which seem the most likely are the oxidation of titanomagnetite by its partial replacement with titanomaghemite, or the incipient submicroscopic unmixing of magnetite and ilmenite rich phases; both processes may occur. By the first process (which may take place at the surface through the absorption of seawater) parts of strongly magnetized grains may have been replaced by titanomaghemite with a comparatively weak CRM. By the second process (which might occur during even very mild hydrothermal alteration of buried flows in the volcanic zone and which is perhaps simulated in the experiments mentioned above) the original TRM is replaced by a CRM in the unmixed magnetite rich phase. This causes a decrease in the intensity and an increase of Curie and blocking temperatures with distance from the axis. Schaeffer and Schwarz[5] have also independently invoked a similar process.

Ridge Model

These results relate to magnetic models of the ocean ridges. The thickness of the magnetized layer required to generate the magnetic pattern may be calculated using the mean intensities for each physiographic province. The thickness obtained is 200 m for the median valley and 1 km for the crest mountains and high fractured plateaux. This suggests that igneous activity outside the median valley has thickened the magnetized layer by a factor of five. The remarkable preservation of the reversal sequence in the geomagnetic anomaly profiles indicates that the magnetic layer is formed within a few km of the axis[20,21], and that lateral thickening of the magnetic layer has been negligible. If, moreover, the decay of intensity in surface samples is due to chemical demagnetization through extended contact with sea water, then only a proportion of flows will be affected. Most will soon be covered and subject only to mild hydrothermal effects for the short time they remain in the warm volcanic zone. The mean intensity of magnetization of the extrusive layer may then fall between the observed surface curve and the decay curve for bottom flows. The proposed model is set out in Fig. 2. The thickness of the magnetized layer is about 200 m and approximately constant across the entire ridge. The growth lines define successive age slices, and in their upper parts these are composed of comparatively weakly magnetized[1] intrusive rocks (gabbro and diabase) and metamorphic rocks (greenstones, serpentinized peridotite) rocks capped by a thin volcanic layer which is more magnetic by a factor of ten.

The model is based on magnetic evidence, but is consistent with the dredge haul stratigraphy and seismic velocities (to be published by D. Barrett and F. Aumento). In this model it is the oxidation of the titanomagnetics (as recorded by the increase in Curie and blocking temperatures) that is mainly responsible for the axial anomaly being about twice as large as those on either side, so that over the more rapidly spreading ridges in which material moves rapidly sideways out of the warm volcanic zone this anomaly contrast should be less. It is perhaps noteworthy that over the fast spreading East Pacific Rise the axial anomaly has a magnitude very similar to those on either side, and the intensities of magnetization calculated from the anomalies themselves (by the inverse method) show no systematic variation with distance from the axis[22].

The opaque mineralogy and magnetic properties of submarine and subaerial basalts are so different that they should (when taken together with many other geological factors) prove to be a useful tool for the identification of old oceanic crust, which is a problem of great general interest. The hypotheses of continental drift and seafloor spreading predict that if two plates of lithosphere containing oceanic crust are driven together, one over the other in a subduction zone, then their present boundary should be marked by remnants of the ocean floor. These remnants may then be used to map the boundaries of old plates. In this way large quantities of primitive oceanic basalt could have been incorporated into the continental crust. These basalts we observe to contain abundant disseminated sulphides which later may be concentrated into useful deposits by hydrothermal processes. Many greenstones were originally submarine lavas so that the ultimate source of the metalliferous deposits, which are commonly associated with them, is to be sought in an ancient spreading rift system.

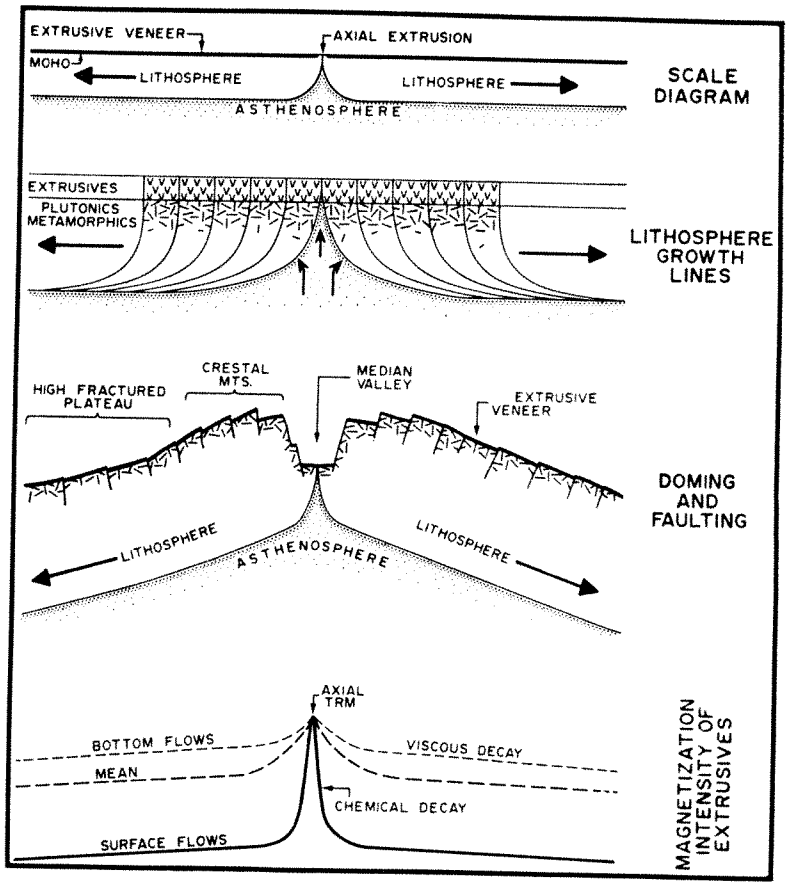

Fig. 2. Proposed model for the Mid-Atlantic Ridge at 45° N. The top two diagrams illustrate the growth of the lithosphere, and the third diagram the effect of doming and faulting. The thin volcanic veneer responsible for the marine magnetic anomalies is about 200 m thick and relatively non-magnetic plutonic and metamorphic rocks are exposed along the infacing escarpments. At the bottom the observed (thick line) and assumed intensity distribution within the volcanic layer is given. The mean curve is constructed assuming that the upper quarter of the flows have been affected by maghemitization due to sea water contamination, and three-quarters of the flows have been affected by very mild hydrothermal alteration (unmixing of titanomagnetite) due to burial in the warm volcanic zone. Beyond the median valley only very slow viscous decay occurs. The intensity values can be scaled from Fig. 1.

We thank the masters, officers and crews of CSS Hudson and MV Theta, John Brooke (who obtained the drill core), Keith Manchester, W. A. Robertson, David Ross, Jean Roy and P. H. Serson for help.

Formation of the Indian Ocean

by
M. W. McELHINNY
Department of Geophysics and Geochemistry,
Australian National University,
Canberra, ACT, Australia

Palaeomagnetic results suggest a possible sequence for the fragmentation of the land masses around the Indian Ocean.

PALAEOMAGNETIC data from the southern continents[1] are now sufficiently detailed to confirm that du Toit's reconstruction of Gondwanaland[2] is essentially correct. The data are compatible with Gondwanaland remaining as a unit for the whole of the Palaeozoic, for the palaeomagnetic poles all lie on a common polar-wander path with the continents reconstructed[1]. Whether or not Madagascar should be placed to the west or east of India was indeterminate and controlled entirely by the precision with which the position of India could be located, because there are no Palaeozoic results for Madagascar. For Africa and South America, it has been shown that the agreement of the pole paths continues up to the end of the Triassic, with the divergence occurring between the Late Triassic and Early Cretaceous[3]. The first opening in the South Atlantic thus took place within these limits.

Recently, some K–Ar ages have been determined for the Rajmahal Traps of India[4], and, surprisingly, these show that they are only 100 to 105 m.y. old (Albian). These volcanics had previously been regarded as Jurassic in age, a factor that led most analysts of Mesozoic palaeomagnetic results[5–8] to suggest that India was adjacent to Western Australia rather than East Africa in the original configuration of Gondwanaland. For each of the four principal circum-Indian Ocean fragments of Gondwanaland there are now palaeomagnetic results that fall in the time range 95 to 110 m.y. (see Table 2), and for Madagascar new results for the Late Cretaceous have been reported[9]. These measurements relate to the time either just preceding the break-up of the super-continent or else during which the dispersal of the fragments was taking place, and they enable some suggestions to be made regarding the history of the formation of the Indian Ocean and the future interpretation of sea-floor spreading data.

Gondwanaland during the Palaeozoic and Early Mesozoic

The essential features of the Palaeozoic and Early Mesozoic (Triassic and Jurassic) palaeomagnetic results from Gondwanaland are summarized in Table 1, and I have used them to derive the Gondwanic configuration of Fig. 1. The palaeomagnetic poles tend to group about four positions during the Palaeozoic, rather than to lie on a continuous curve. These "quasi-static" intervals[6] (designated as groups *A*, *B*, *C* and *D*) are separated by short intervals of time during which the pole moved from one stable position to the next. From a recent analysis of the Phanerozoic polar-wander path for India[4], it is now possible to place a further constraint on this continent's position in Gondwanaland. The reconstruction of Fig. 1 enables the Indian Triassic poles to fall in the same region as Triassic poles for South America, Mesozoic poles for Africa and Jurassic poles for Antarctica, without seriously upsetting the agreement of the Indian Palaeozoic poles with the common polar-wander curve. This restricts the position of Madagascar to the region between the west coast of India and the east coast of Africa. The reassembly so obtained is then the same as that confirmed by a computer fit of the continental shelves[10].

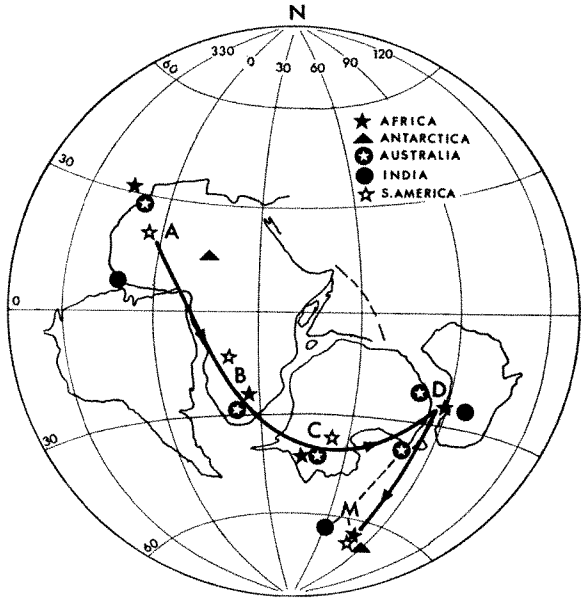

Fig. 1. Reconstruction of Gondwanaland based on the mean palaeomagnetic poles listed in Table 1. Africa is placed in its present coordinates on an equatorial equal area projection. The common polar-wander curve is shown, commencing at the group *A* poles in Cambrian times through to group *M* in the Triassic–Jurassic. Note that the Australian group *M* pole diverges from the rest.

Although the Mesozoic poles for Australia form a close group, their mean does not overlap with those from the other continents as illustrated in Fig. 1. One is forced to conclude that Australia broke away from the rest of Gondwanaland during the Early Triassic. This is puzzling because sea-floor spreading data from the south-east Indian Ocean between Australia and Antarctica[11] suggest that the break between them took place only 43 m.y. ago. Cretaceous palaeomagnetic results from Australia

Table 1. GROUP MEAN PALAEOMAGNETIC POLES FOR THE GONDWANIC CONTINENTS FOR THE PALAEOZOIC AND MESOZOIC

Continent	Group *A*	Group *B*	Group *C*	Group *D*	Group *M*
Africa[7]	31 N, 18 W (3)	26 S, 26 E (1)	46 S, 40 E (1)	27 S, 89 E (1)	64 S, 81 E (9, Tr-K)
Antarctica[8,24]	28 S, 10 E (1)	—	—	—	54 S, 140 W (4, Jur)
Australia[23]	12 S, 4 E (2)	77 S, 12 W (3)	73 S, 147 E (1)	44 S, 135 E (6)	48 S, 151 E (10, Tr-K)
India[4]	28 S, 32 E (1)	—	—	26 N, 132 E (2)	20 S, 128 E (3, Tr)
S. America[22,25,26]	15 N, 38 W (5)	28 S, 34 W (1)	62 S, 14 W (4)	—	82 S, 154 W (7, Tr)

Number of poles making up each mean is given in parentheses. Approximate ages are: Group *A*, Cambrian to Silurian; Group *B*, Devonian to Lower Carboniferous; Group *C*, Upper Carboniferous; Group *D*, Permo-Carboniferous; Group *M*, Mesozoic (as indicated).

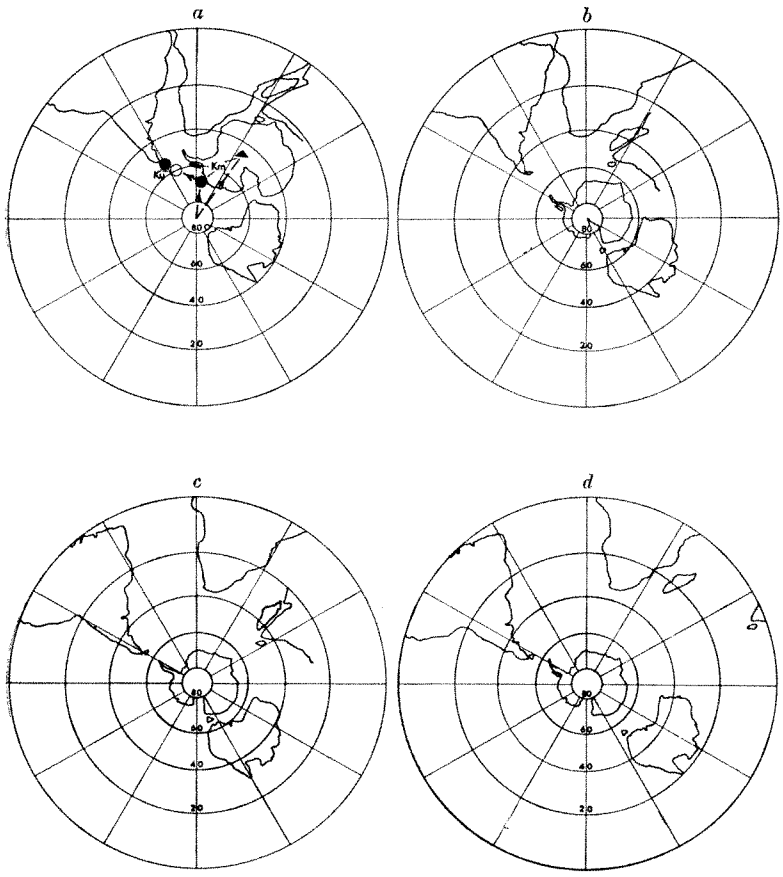

Fig. 2. The break-up of Gondwanaland showing approximate positions of the fragments at four stages. Polar stereographic projections. *a*, Triassic to mid-Jurassic, based on the group *M* poles of Table 1. The subsequent mid-Cretaceous (Km) poles for India and Madagascar (open circle) are indicated using the symbols of Fig. 1 and data of Table 2. *b*, Mid-Cretaceous, using poles in the range 95–110 m.y. from Table 2. *c*, Upper Cretaceous to Palaeocene, where India and Madagascar are located using the poles of Table 2, and the other continents are located from sea-floor spreading data[11,16] as also in (*d*) Miocene.

and Antarctica (discussed later) are again compatible with the Australia–Antarctica link as in Fig. 1, but the Jurassic data are not. Because all the Mesozoic palaeomagnetic measurements in Australia are from rocks in eastern Australia, Irving and Robertson have suggested[12] that eastern Australia detached itself from the rest of Australia and Antarctica during the Early Triassic and then rejoined it again later. Although this might seem fortuitous, Rod has suggested[13] possible geosutures in eastern Australia that could be compatible with this suggestion, but, in making a possible reassembly for the Triassic to mid-Jurassic, the whole of Australia has been moved to conform with the palaeomagnetic results as shown in Fig. 2*a*.

Cretaceous

Results from the four circum-Indian Ocean continents in the time range 95 to 110 m.y. are summarized in Table 2. The Andean Intrusive Suite, Antarctica, previously cited as Upper Cretaceous to Eocene, is now associated with isotopic dates around 100 m.y.[14]. For South America, there are only results from the Lower Cretaceous Serra Geral formation[15], but this continent will not be considered further in relation to the formation of the Indian Ocean. The successive positions of South America shown in Figs. 2*b*, *c*, *d* are those inferred from sea-floor spreading in the South Atlantic[16]. The positions of the other continents can only be related to a single (or mean) palaeomagnetic pole for each period. The continents are placed in latitude and azimuthal orientation with respect to the pole at the centre, but the longitude remains indeterminate. Thus the successive positions of the circum-Indian Ocean continents shown in Fig. 2 during the break-up of Gondwanaland have arbitrary longitude.

Table 2. CRETACEOUS PALAEOMAGNETIC POLES FROM GONDWANALAND

Continent	Mean pole position	Age
Africa[7]	62 S, 80 E (1)	106–111 m.y.
	60 S, 82 E (1)	116–128 m.y.
Antarctica[8]	86 S, 2 W (1)	96 m.y.[14]
Australia[8]	54 S, 147 E (2)	93–104 m.y.
India[4]	10 S, 117 E (3)	100–105 m.y.
	30 S, 107 E (1)	Late Cretaceous
	33 S, 101 E (2)	65 m.y.[19]
Madagascar[9,27]	76 S, 44 E (3)	Late Cretaceous
S. America[15]	78 S, 54 E (1)	120–135 m.y.

Number of poles making up each mean is given in parentheses.

The pole positions for both Africa and Australia remain unchanged throughout the Mesozoic, whereas the mid-Cretaceous poles for India and Antarctica differ from their Triassic and Jurassic poles respectively as illustrated in Fig. 2*a*. Included on the same diagram are the Late Cretaceous poles for India and Madagascar (Table 2). The important point to note is that the Late Cretaceous Madagascar pole not only plots close to the Late Cretaceous Indian pole, but also lies on the path joining the Indian mid and Late Cretaceous poles. This suggests that the proximity of India and Madagascar was maintained at least up to the latter part of the Late Cretaceous (say 70 to 80 m.y. ago).

The diverging pole positions for India and Antarctica and Africa for the mid-Cretaceous show two things. First, the India–Madagascar–Antarctica block must have broken away from Africa between the mid-Jurassic and mid-Cretaceous, opening up the Indian Ocean for the first time. This estimate is compatible with those made by Le Pichon and Heirtzler[11] and Smith and Hallam[10]. Second, the India–Madagascar block must have subsequently separated from Antarctica. It is possible that this last break may be related to the extrusion of the Rajmahal Traps around 100 m.y. ago. By the mid-Cretaceous, the palaeomagnetic poles indicate a situation as in Fig. 2*b*. The important point that arises is that both Antarctica and the India–Madagascar block are situated farther south of Africa, so that although Antarctica and India are separating, this fragment of Gondwanaland has moved southwards. Most discussions of the limited sea-floor spreading data for the Indian Ocean[10,11,17] tend to assume that India moved always in a northerly direction to its present position from one adjacent to East Africa.

Late Cretaceous to Palaeocene

By the close of the Mesozoic era, the opening between Antarctica and Africa is almost complete and the south-west part of the Indian Ocean has opened (Fig. 2*c*). This is, of course, consistent with Vine's suggestion[18] that the south-west part of the Indian Ocean ridge is a dead ridge and has not been the site of measurable spreading since the Mesozoic. The subsequent motion of India and Madagascar is northwards relative to Antarctica during the Late Cretaceous, and the break between them must occur near the Mesozoic–Cainozoic boundary. It is tempting to relate this to the extrusion of the Deccan Traps, which K–Ar dates now place firmly at around 65 m.y.[19]. Davies sup-

poses[20] that India and the Seychelles parted company some time in the Palaeocene, relating this to the Deccan Trap vulcanism. One might surmise that the Seychelles formed part of an India–Madagascar block and that rupture of the Seychelles and India was also accompanied by the rupture of India and Madagascar. This occurred at a latitude of 30° S as shown in Fig. 2*c*, at which time the Carlsberg ridge was establishing itself.

Cainozoic

On the scheme just outlined, spreading from the Carlsberg ridge during the Cainozoic involves the separation of India on one side and Madagascar and the Seychelles on the other. Note that Africa is not involved. The rapid northward movement of India occurs during the Cainozoic[21], so that by the Miocene (Fig. 2*d*) it had crossed the equator. The final phase is the separation of Australia and Antarctica, which sea-floor spreading data suggest began 43 m.y. ago[11].

The Quaternary deposits of the Alboran Sea and associated sediment dispersal patterns, and geographic and tectonic setting of the region are closely similar to those of some ancient flysch basins preserved in the geological record.

Flysch is a popular geological term applied to distinct sedimentary deposits exposed in many of the world's tectonic belts. Most geologists in the Alps, where the term was coined[1], would designate as flysch the type of sequences described by Tercier[2] and other workers[3,4]: (*a*) thick accumulations of detrital or terrigenous deposits; (*b*) variable lithologic complexes usually consisting of regular alternations of sandstones and micaceous shales with interbedded conglomerates or limestones; and (*c*) formations of marine origin. Furthermore, the palaeogeographic setting as inferred from diverse stratigraphic and tectonic investigations suggests that flysch units in the Alps and other regions such as the Apennines and Carpathians would be characterized by deep, partially isolated marine basins bordered by narrow shelves and relatively steep dissected slopes and by discontinuous and tectonically active cordilleras. These marine basins generally received large volumes of terrigenous deposits during stages of advanced orogenic development[5]. Agreement, however, as to an exact definition of the term has yet to be reached[6]. Most flysch units described to date are consolidated formations of pre-Pleistocene age.

Because of the widespread and volumetric importance of flysch in the rock record and because the depositional history of most flysch units is still poorly understood it is essential to seek potential analogues of such deposits that may now be accumulating in present-day oceans or that may have been deposited in marine basins in the recent geological past. In this respect, preliminary results of a study of the Quaternary sedimentation patterns in the Alboran Sea in the western Mediterranean are most useful.

Geographical and Geological Setting

The partially land-locked Alboran Sea, approximately 160 km wide and 320 km in length, lies between the Betic Cordillera on the Iberian peninsula and the Moroccan Rif on the North African margin. It connects with the Atlantic at the Strait of Gibraltar to the west and with the Balearic Basin to the east. Sea floor topography of this region is particularly complex. There is almost no shelf platform, and submerged ridges, seamounts, basins and submarine valleys characterize the region (charts in ref. 7, and C. E. G., C. B., D. J. S., Blavier, P.,

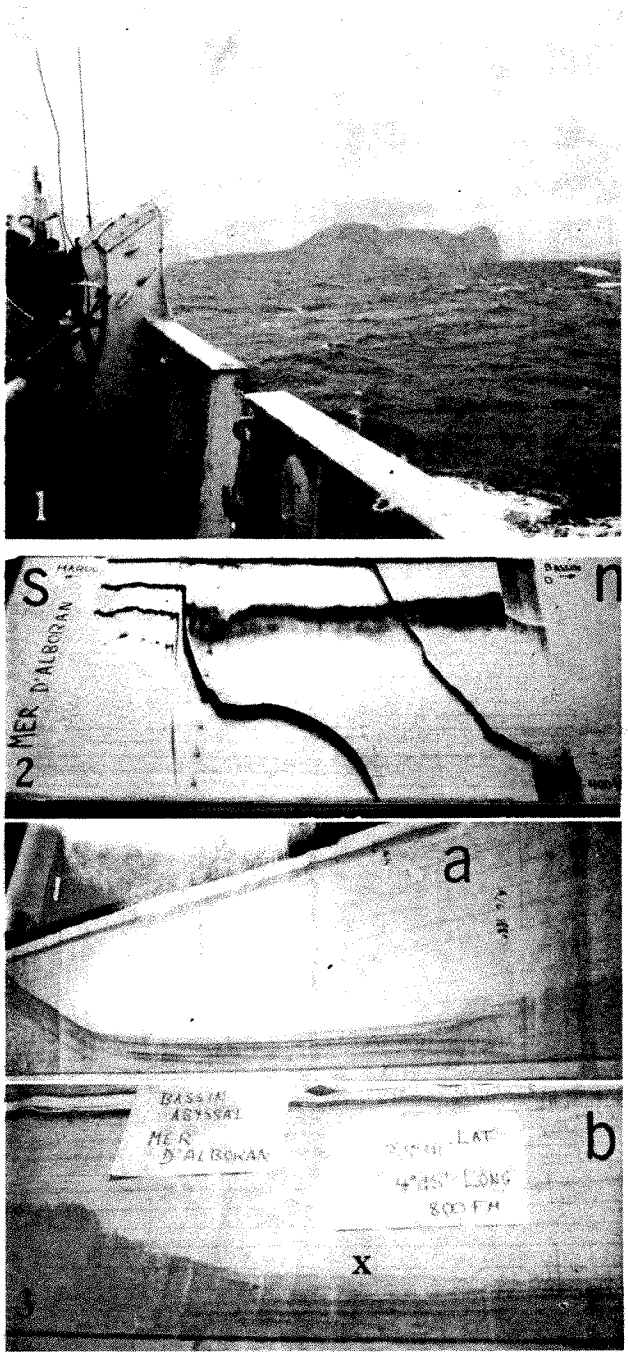

Fig. 1. (1) Alboran Sea east of the Strait of Gibraltar. Ship is positioned above head of Gibraltar Submarine Valley in which much sediment is funnelled south-eastward to the Western Alboran Basin. Gibraltar and Great Europa Point are in the distance. (2) Steep slopes (> 10°) as recorded on PDR record obtained north of Xauen Bank; note dense deep-scattering layer. (3) Two N–S oriented PGR profiles across the Western Alboran Basin plain and basin aprons. Note flysch-like alternating sequence of laterally continuous reflectors (thin sand turbidites) and acoustically transparent mud section. Wedge of sediment at base of slope (×) is a large allochthonous slump mass that has been emplaced on the southern margin of the basin by gravity sliding.

and Tonarelli, B., in preparation). Slopes to 11° are encountered (Fig. 1). Attention has previously been paid to the predominant NE–SW trend of large morphological features including the volcanic Xauen Bank–Tofiño Bank–Alboran Ridge extension. This lineation undoubtedly reflects NE–SW structural trends including major faults[8] and volcanic extrusives[9]. The region has been subjected to almost continuous tectonic activity since the late Mesozoic[10]. Compressional development affected the region during the Cretaceous and Tertiary as a result of movement of the African against the European blocks, and possibly the counter-clockwise rotation of the Iberian peninsula. Opening of the Alboran Sea in Ponto-Pliocene time[11,12] reflects distension accompanying lateral displacement of the Afro-European blocks. Volcanic activity[9] became important during this down-drop and separation, or *effondrement*, and seismic surveys show that more than 1 km of terrigenous sediment fill has accumulated in this region since the beginning of the Pliocene[13,14]. Local folding and faulting of the Plio-Pleistocene fill indicates that the region has once again been subjected to orogenic compression. Submergence of 2,000 year old archaeological sites was caused by recent downward displacement resulting from tectonic movements[15]. The presently active seismic belt extending eastward from the Azores to North Africa[16] continues to affect this region. Concurrent tectonic mobility and rapid sedimentation, essential prerequisites for flysch deposition, have thus been predominant characteristics of the Alboran Sea since the Pliocene.

Nature of the Depositional Fill

Of particular interest is the sediment fill in the Western Alboran Basin, the largest (24 by 37 km) and deepest (just over 1,500 m) basin plain (Fig. 2) in this sector of the Mediterranean. This oval basin lies approximately 110 km east-south-east of the Strait of Gibraltar and 100 km south of Malaga, Spain. The NW–SE trending Gibraltar Submarine Valley (80 km long and 5 to 10 km wide) links this basin plain with the Ceuta and Gibraltar Canyons near the Strait. A large seamount chain lies north-east of the basin; isolated mounts (probably volcanic necks) are found north of the basin. Extensive high resolution Precision Graphic Recorder (PGR) coverage (2,220 km) and dense coring (49 large diameter, 120 mm) sphincter cores[17] collected during several Nato-SACLANT cruises serve to define the unconsolidated sediment pond (Fig. 2A). The dense PGR net consists of twelve N–S profiles extending from the African to Spanish shelves and spaced 8 or less km apart, six E–W profiles, an NW–SE profile close to the Gibraltar Submarine Valley and an NE–SW profile along the Spanish margin (profiles detailed in ref. 18). These profiles highlight the geometry and attitude of subbottom strata. The PGR used with an EDO echo sounder transmitting pulses at 12 kHz provides extremely high resolution to a depth of about 30 m below the surface of the sediments.

The survey defines an assemblage of terrigenous, gravitational and hemipelagic deposits that recall those of typical ancient flysch. Thin sand layers that extend across the basin plain and basin aprons alternate with fine-grained acoustically transparent sediments (Fig. 1). Also noted on PGR profiles are allochthonous 10 to 15 m thick slump masses, covering at least 36 km², concentrated on the edge of the basin plain and in the basin apron at the base of 1° to 6° slopes. Where cored, these large-scale gravity slide deposits reveal anomalously steeply dipping (to 20°) sand layers and some contorted strata. Distinct reflectors concentrated in the basin plain are recognized in cores as thin graded and laminated sand units of relatively uniform thickness (1 to 15 cm) and subbottom depth. These units are believed to represent short-term gravitative (turbidity current, bottom flow and traction) events. Most sand layers, laterally continuous across most of the basin, serve as precise stratigraphic horizons. The nature of these layers is described in detail elsewhere (to be published by C. E. G., C. B., D. J. S., P. Blavier and B. Tonarelli, and in ref. 18).

Mud, predominantly silty clay, accounts for at least 95 per cent of the Holocene fill of the Western Alboran Basin. This mud, not deposited from a simple rain of pelagic material onto the basin floor, has a multiple origin. Mud distribution, determined from cores and high-resolution seismic records, is closely related to topography. Total thickness of the Holocene section is

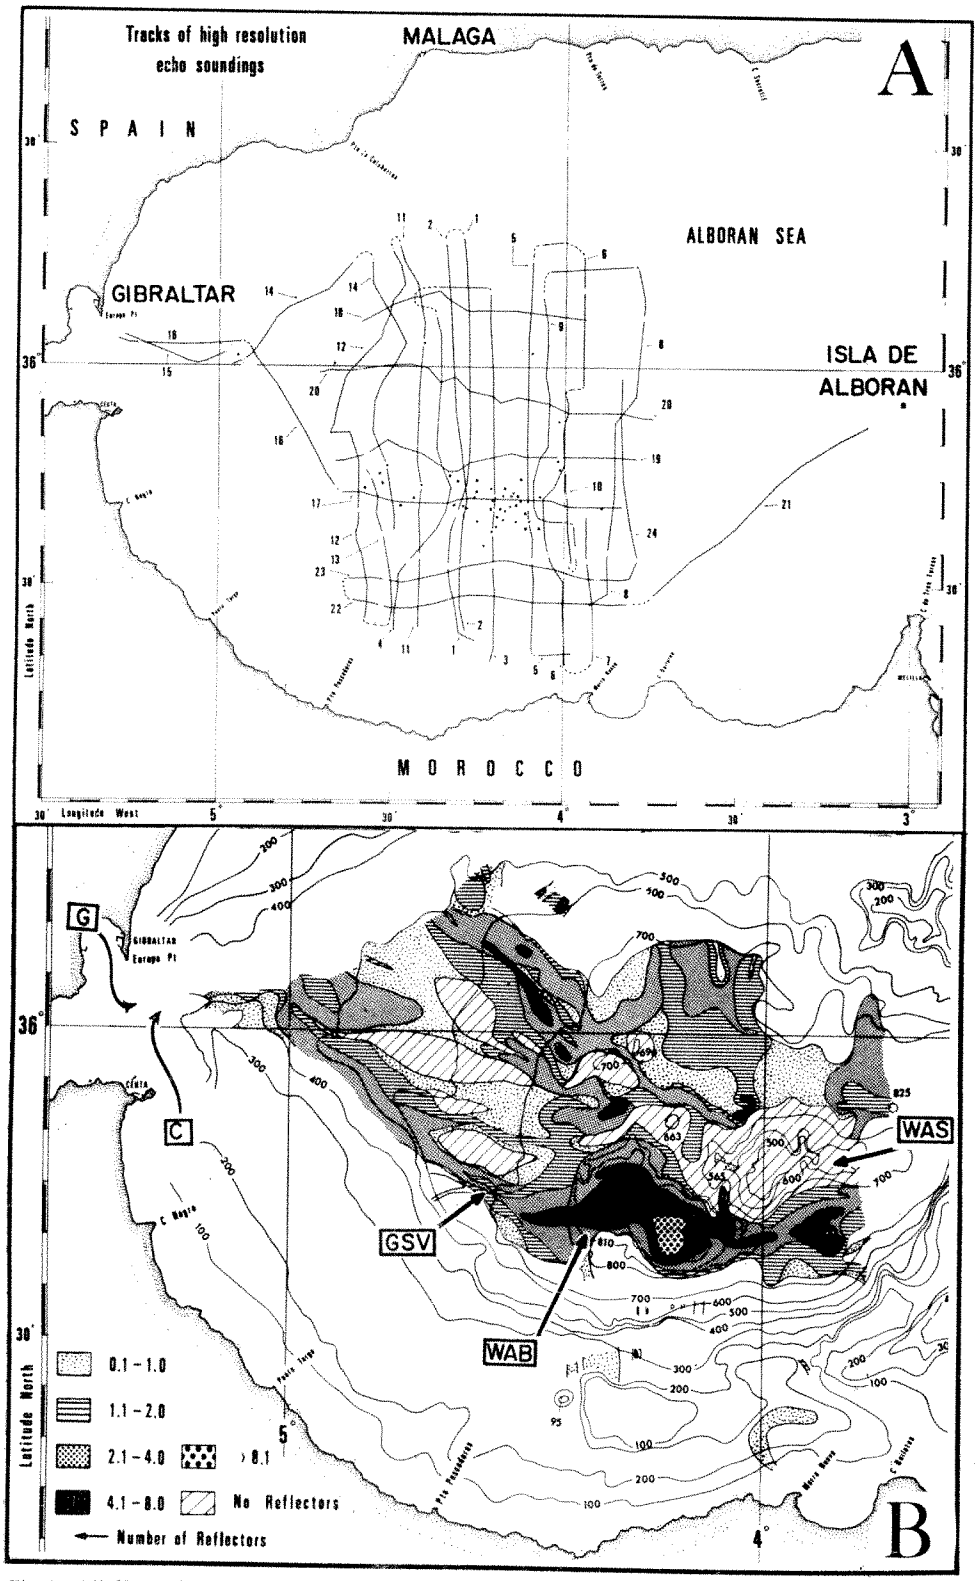

Fig. 2. (*A*) Chart of study area showing the net of available PGR profiles and cores (shown as dots); (*B*) chart showing distribution and total number of sand layers per 20 m section as obtained from the PGR records. Note the close relation of number of beds with topography. *G*, Gibraltar Canyon; *C*, Ceuta Canyon; GSV, Gibraltar Submarine Valley; WAB, Western Alboran Basin; WAS, Western Alboran Seamount chain. Base chart by courtesy of SACLANTCEN.

approximately 2 m on basin slopes and increases to more than 4 m (sedimentation rates to about 35 cm/1,000 years) in the near-horizontal basin plain. Thickest mud deposits are therefore localized in lows where thin sand layers most abound. These deposits are hemipelagic in composition: lutite with planktonic and benthonic foraminifera, deep and shallow water ostracods, and plant fibres. Components are, at least in part, near-shore in origin.

At least 10 to 20 per cent of mud core sections are parallel and cross-laminated as shown in X-radiographs[18], suggesting that bottom traction transport may be important in the deposition of mud in the basin. Bottom currents have also truncated the top of sand layers and concentrated microfossils in thin laminae. A few subtly graded mud units are probably mud-turbidites. Another facies type consisting of homogeneous mud layers with scattered microfossils (comprising more than half of the Holocene fill) reflects more regular deposition from less dense suspension layers[18].

Dispersal Patterns

Coarse-fraction provenance. Sandy layers represent only about 5 per cent of the total late Pleistocene and post-glacial sequence but are most valuable in interpreting the paths of sediment transport into the Alboran Sea. The regional distribution and number of sand reflectors per upper 20 m of section as noted on PGR records has been plotted (Fig. 2*B*). The resulting distribution pattern indicates concentrations of finger and tongue-shaped sand units oriented normal to the slope. The concentration of sand layers is highest in the Western Alboran Basin plain and other topographic lows including submarine valleys and small depressions between seamounts. From these data it is possible to infer the predominant dispersal path of silt and sand (Fig. 3). Arrows showing transport directions of coarser material have been assigned on the basis of (*a*) attitude of subbottom reflectors, including imbrication of layers, and (*b*) termination of reflectors, usually near the base of slopes. A multiple source origin

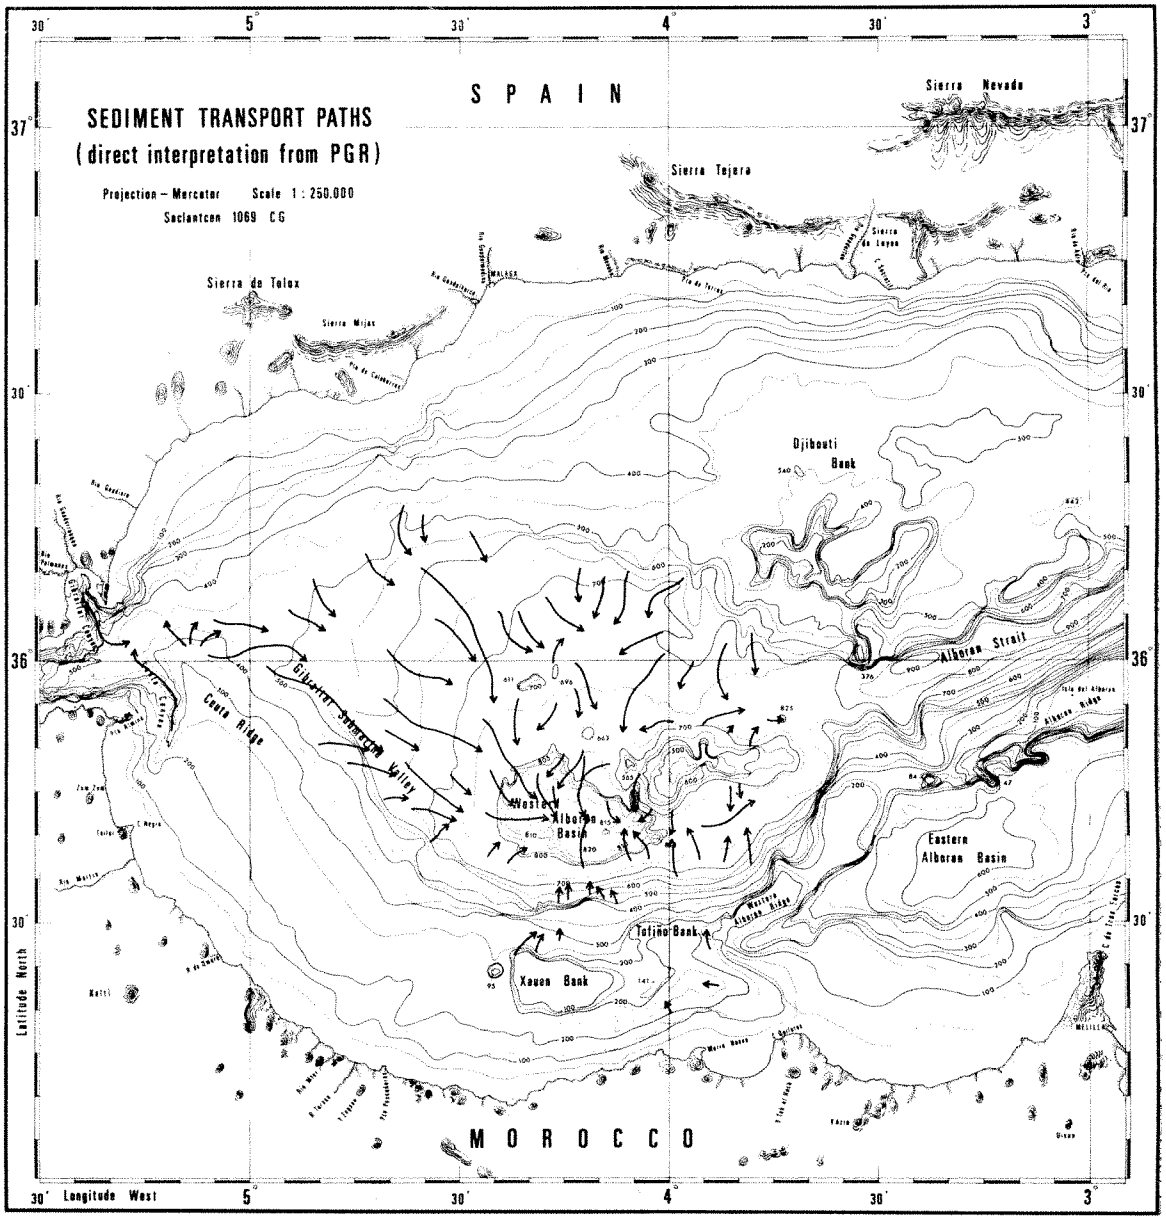

Fig. 3. Sediment dispersal (arrows determined from analysis of PGR records in Fig. 2*B*), showing inferred transport paths of silt and sand into the western part of the Alboran Sea. This style of ponding, including the multi-source origin of sediments, calls to mind terrigenous depositional patterns of certain ancient flysch basins. Base chart by courtesy of SACLANTCEN.

must be invoked to explain the diversity of sediment transport directions: material is transported from (*a*) extrabasinal source areas (sediments transported to the Spanish and Moroccan coasts by rivers and torrents draining the Betic and Rif (Cordilleras)) and (*b*) intrabasinal sources within the Alboran Sea (steeper upper slopes, ridges, banks and seamounts that have shed material downslope). Similar multiple-source ponding has been postulated for some ancient flysch basins[19–22].

A significantly large volume of sediment has been derived from the north-west quadrant, presumably the Spanish margin. Canyons and other linear depressions have channelized flow basinward. One turbidite layer, early Holocene in age, can be followed laterally for more than 65 km and seems to have originated in the Gibraltar region. There is good evidence that the Gibraltar and Ceuta Canyons and Gibraltar Submarine Valley funnel near-shore sediments to the Western Alboran Basin. The Moroccan margin and shallow banks such as Xauen and Tofiño Banks also provide sediment to the Alboran Sea[18].

Fine-fraction provenance: higher sedimentation rates of hemipelagic muds in the deeper parts of basin plains than on adjacent slopes must be accounted for. It is probable that deep water mass movement (dense Mediterranean undercurrent outflow) is deflected by topographic lows thus concentrating fines in such areas as the Western Alboran Basin. Currents near the bottom would account for the truncation of the upper parts of sand turbidites and for the concentration of microfossils as distinct layers. The intensity, direction and constancy of deep seawater movements in this area, still poorly known, are presently under investigation.

The predominant source of supensate in fine-grained turbid flows are floods that seasonally inject material at fluvial point sources along the mountainous Moroccan and Spanish margins. Winter storm and wave activity eroding the adjacent coast line also bring fine sediments into suspension. A probable third source of fines is extra-basinal: (*a*) fines carried by the low density surface Atlantic water entering through the Strait of Gibraltar and by deeper dense Mediterranean water entering the Alboran Sea from the east. It seems that most of the mud in the basin has been deposited from slowly moving suspension-rich layers.

Another mechanism may also account for some of the lutite-rich section: deposition from gravity controlled turbid flows. Mud transport paths may, in such cases, be similar to sand dispersal patterns. It is noted, for instance, that the thickness of mud in the lowest parts of the Gibraltar Submarine Valley is 25 per cent to 30 per cent lower than in the Western Alboran Basin as shown on PGR profiles. A possible hypothesis is that mud and sand-charged bottom flow occasionally moves through the Gibraltar Submarine Valley. Velocity of such flows may be too high for deposition of fines in the canyon; settling of lutite and associated benthonic and planktonic microfossils occurs toward the centre of the basin plain as current velocities decrease[18]. It would be difficult to distinguish between deposits from low density turbidity currents and those from low density suspension layers transported by slow moving water masses[23].

Modern Flysch Basins in the Mediterranean?

If one adheres to the cited criteria of flysch outlined in the introduction of this article it becomes apparent that most Quaternary deep-sea sediments covering the world's deep ocean floors have been deposited in geographic sites and under conditions that differ significantly from those of basin of Alpine orogenes. The large open ocean basins such as the present North Atlantic are generally bordered by more gentle slopes, larger abyssal plains and wider shelves than those of former flysch basins of the Alpine type. Such basins tend to receive smaller amounts of sediment per unit area than smaller somewhat shallower partially land-locked flysch basins of the Alpine type. The margins of ocean basins such as those off north-east North America have been tectonically quite stable. Furthermore, it is difficult to predict the future tectonical development of a present-day ocean basin, more less recognize its present orogenic phase. It is reasonable therefore to question, as some workers have[5], whether any modern oceanic deposits can be accurately designated as flysch for that term is usually applied by land geologists working in the Alps, Apennines, Carpathians and other mountain belts.

We propose that the Alboran Sea has been receiving a Quaternary flysch-type sediment fill during Quaternary time: (*a*) the terrigenous fill consists of gravitative and hemipelagic sequences which, if lithified and exposed, would be recognized as a shaly flysch of which there are many examples in the Alps and elsewhere; (*b*) sediment ponding[24,25] and associated sediment transport processes appear to be similar to those inferred for some ancient flysch basins; (*c*) the geographic setting and crustal mobility of the region directly affect depositional style and rates in a manner that also calls to mind those postulated for ancient flysch deposits.

Marine surveys have now perhaps reached a level of sophistication such that it should be possible to evaluate the modern deep-sea record so as better to understand the rock record. We believe that the Alboran Sea and other selected basins of the Mediterranean should prove to be valuable natural laboratories to test the hypothesis that there are modern flysch basin counterparts.

We thank SACLANTCEN (La Spezia, Italy) for support of this particular study, an outgrowth of a larger investigation on the Alboran Sea. We also thank the captain, officers and men of the Maria Paolina G. and our colleagues, Messrs P. Blavier and M. Catello, for their help in obtaining the data at sea, and B. Tonarelli for preparing the detailed chart used as a base for Figs. 2 and 3. Support in the form of a travel grant and funding for research in La Spezia and Washington was provided to D. J. S. by the Smithsonian Institution Research Foundation and the Office of Naval Research, Washington.

PHYSICAL SCIENCES

Sunspots and Planetary Orbits

THE possibility of a relationship between the periods of the sunspot cycle and the periods of the rotation of the planets has been investigated by several authors[1–5]. Such an interaction could be mediated by non-linear processes of gravitational wave conversion of the type which may, for example, be responsible for the acceleration of the equator of the Sun[6,7]. On the face of things, the most likely relationship should be that between the sunspot cycle and the period of rotation of Jupiter, gravitationally the dominant planet, but non-linear may imply that cross modulation products representing the combined effects of two or more planets may be the most easily recognizable.

What follows is a successful correlation between the harmonic periods of the sunspot cycle as revealed by Anderson's single and double period analysis of the sunspot cycle and the cross modulation products of the sidereal periods of the four largest planets, Jupiter, Saturn, Uranus and Neptune. The reciprocals of the cross modulation frequencies (in years) are shown in Table 1.

Table 1. COMPARISON OF SUNSPOT CYCLE AND PLANETARY ORBIT ANALYSIS

Planets	Frequency (days^{-1})	Periods (yr)		338 Year fundamental	Anderson's sunspot cycle analysis (yr)		
		Upper sidebands	Lower sidebands	Harmonic No.	Single period	Double period	Relative amplitude
J + S	0·000323753	8·46		40	None		
J − S	0·000137865		19·86	17	9·95	19·9	13
J + S + U	0·000356342	7·68		44	None		
J + S − U	0·000291164	9·40		36	None		
J − S + U	0·000170454		16·06	21	8·05	16·1	13
J − S − U	0·000105276		26·01	13	13·00	26·0	11
J + S + N	0·000340367	8·04		42	8·05	16·1	13
J + S − N	0·000307139	8·91		38	8·90	17·75	26
J − S + N	0·000154479		17·72	19	8·90	17·75	26
J − S − N	0·000121251		22·58	15	11·26	22·5	70
J + S + U + N	0·000372956	7·34		46	7·35	14·7	3
J + S + U − N	0·000339728	8·06		42	8·05	16·1	13
J + S − U + N	0·000307778	8·90		38	8·90	17·75	26
J + S − U − N	0·000274549	9·97		34	9·95	19·9	13
J − S + U + N	0·000187068		14·64	23	7·35	14·7	3
J − S + U − N	0·000153840		17·80	19	8·90	17·75	26
J − S − U + N	0·000121890		22·46	15	11·26	22·5	70
J − S − U − N	0·000088662		30·88	11	15·36	30·75	10

The upper sideband values match components of Anderson's single period sunspot analysis, and the lower sidebands match double period components. These modulation products were calculated and grouped together as upper and lower sidebands of the orbital period of Jupiter:

Planet		(Sidereal period)$^{-1}$
Jupiter	(J)	0·00023080895 days^{-1}
Saturn	(S)	0·00009294371 days^{-1}
Uranus	(U)	0·00003258899 days^{-1}
Neptune	(N)	0·00001661419 days^{-1}
J − S − U + N	=	0·00012189044 days^{-1}
	=	22·46 yr

Periods from the Explanatory Supplement, 1961 Epheremis (Great Britain).

Six of seven of the highest amplitude sunspot harmonic components match these sideband periods. There seems to be a definite relationship between the orbital periods of the planets and the periodic nature of the sunspot cycle, and the relationship depends on a non-linearity in the solar energy conversion system.

We thank Dr G. L. Hower for assistance and comment.

Mid-latitude Atmospheric Emission of N_2^+ First Negative Bands

THE first negative bands of N_2^+ are excited in the atmosphere by energetic particle precipitation. The cross section data of Srivastava and Mirza[1] imply an associated N_2^+ ion production rate of 14·1 ion pairs per photon in the 0–0 band or 41·5 ion pairs per photon in the 0–1 band, The total ion production rate for all species may be a few times greater and depends on the relative concentration of N_2, a function of the height at which the ionizing radiation is stopped.

Intensities of several Rayleighs for the 0–0 band at 3914 Å have been reported in middle latitudes by Yano[2] and others. The associated total ionization rates of order 10^8 (cm^2 column)$^{-1}$ s^{-1} could be important in the maintenance of the night time ionosphere. Broadfoot and Hunten[3], on the other hand, placed an upper limit of 1 R on the 0–0 band.

Photometric measurements on the 0–1 band at 4278 Å have been made at Adelaide since August 1969. The photometer, with a field of view of 2·5° semi-angle, uses a 3 inch diameter, 8 Å bandwidth interference filter which is periodically tilted to scan through the 4278 Å band head. The output from the photomultiplier is fed to a signal averager. Using total scanning times of 30 min to 60 min (giving detection sensitivities of 0·05 to 0·1 R) observations through more than 10 moonless nights of low geomagnetic activity ($Kp \leq 3$) have revealed that intensities of up to 0·1 may be present during some periods.

We conclude that the night time intensity of the 0–1 band does not usually exceed 0·1 R, implying a maximum total ionization rate of order 10^7 (cm^2 column)$^{-1}$ s^{-1}. Compared with the loss rate of ions through dissociative recombination in the F region this rate is small and cannot

be regarded as a major factor in the maintenance of the ionization through the night. It is also small compared with the ion production rate due to cosmic radiation. Using data of Millikan *et al.*[4], interpolated for the geomagnetic latitude of Adelaide, the total ion production rate due to cosmic radiation is $6{\cdot}5 \times 10^7$ (cm^2 column)$^{-1}$ s^{-1}. As the ionization peaks below 30 km we assume that about 75 per cent of the ions are N_2^+ and, using the cross-section data of Srivastava and Mirza[1], we infer an intensity of approximately 1 R for the 0–1 band. But this estimate makes no allowance for quenching of the $B^2\Sigma_u^+,v'=0$ level of N_2^+ from which the emission arises. This effect reduces the intensity by a factor $(1+s[Q]/A)^{-1}$ where s is the specific rate coefficient for quenching by molecules of number density $[Q]$ and A is the total transition probability for the first negative system. Using the data of Jeunehomme[5] on quenching by N_2 we evalute $s=2{\cdot}1\times10^{-9}$ cm^3 s^{-1} and $A=1{\cdot}4\times10^7$ s^{-1}.

In the 15 to 30 km region where ion production by cosmic radiation is greatest, the number density of N_2 is greater than 3×10^{17} cm^{-3}. The quenching term $s[Q]$ is thus large compared with the emission term A and the intensity of the 0–1 band excited by cosmic radiation will be a very small fraction of 1 R. Even at heights as great as 80 km, the quenching term may be significant in estimating ion production rate or particle energy flux from intensity of the N_2^+ first negative bands. This is particularly relevant to the study of polar cap events associated with proton precipitation.

Search of Electrodynamic Radiative Corrections for Time Variations

A SIMPLE model of the electrodynamic radiative corrections was formed recently by combining different authors' hypotheses of neutrinos of non-zero masses and non-zero electromagnetic properties with the hypothesis of a neutrino sea[1–3]. The central notion of the model is that the magnitudes of these corrections would depend on the temperature and density of the neutrino sea at the point in question and these properties of the neutrino sea would vary in space and time.

The model predicts, among other things, that the different radiative corrections R, in particular the Lamb shifts $S(n,Z)$ (in Robiscoe's notation[1]) and the anomalous magnetic moments of the electron and muon, a_e and a_μ, should show simultaneous, correlated time variations. The model can be developed further by assuming that $S(n,Z)$, a_e, and a_μ are roughly proportional to each other and, originally, to the self-energy of the particle disturbed by the neutrino sea. The smaller ingredients of R, the vacuum polarization and so on, should not perturb this proportionality markedly. The theoretical values of R, calculated from the quantum field theory, represent the secular averages of the corrections R in question. The experimental and theoretical values of R are denoted by $R_{\rm exp}$ and $R_{\rm th}$, respectively. Then the values of the "relative discrepancy"

$$d = (R_{\rm exp} - R_{\rm th})/R_{\rm th}$$

for the different radiative corrections should be roughly comparable with each other. In terms of d, the scarce experimental data can be combined to form better statistics for the search for time variations.

There are, of course, many ways of forming working hypotheses about the origin of the proposed time variation of the neutrino sea. For instance, there may exist in space regions with elevated neutrino density due to gravitational focusing[5]. If a radiative correction is measured while the Earth is passing through such a region, an abnormally large value might be obtained. On the empirical side, there is some slight experimental evidence for the local enhancement of Lamb shifts in solar active regions[1,2]. The working hypothesis that solar activity would be associated with activity in the neutrino sea was therefore accepted. Thus the transient large-scale activity of the Sun might conceivably correlate with changes in R on the Earth. The dates of the measurements reported in the literature, however, are not usually given accurately enough to warrant a correlation with any transient events. Perhaps this possibility could be checked by the authors from their daily results. Meanwhile a correlation with the 11 year cycle could be sought from the available data.

In this context a new model of the solar energy production, due to Sheldon[6], should be considered. Starting from the null result of the solar neutrino experiment of Davis *et al.*[7], Sheldon proposes that the solar nuclear reactions (and the neutrino production) are "switched on" only for a comparatively short period during each 11 year cycle. This model could be taken as the working hypothesis for the present study. The explanation of the null result need not necessarily be accepted simultaneously in the form presented by Sheldon, however, because another explanation is also possible in terms of the present model of neutrino interactions: before reaching the detector, the high energy solar neutrinos might be decelerated to energies under the detection threshold by their interactions with atoms and with the neutrino sea.

As usual I shall use the number of sunspots as the measure of solar activity, and minimum and maximum activity are denoted by $t_{\rm min}$ and $t_{\rm max}$ respectively. For the previous three cycles (numbers 18, 19, and 20 by Bonov[8]) we have approximately $t_{\rm min}=1954{\cdot}2$, $1964{\cdot}7$, and $1976{\cdot}5$, and $t_{\rm max}=1947{\cdot}3$, $1957{\cdot}7$, and $1968{\cdot}4$. The rise of sunspot number is more abrupt than the descent, so the active period may be considered to extend from $t_{\rm max}-1$ yr to $t_{\rm max}+1{\cdot}5$ yr and the quiet period from $t_{\rm min}-3$ yr to $t_{\rm min}+1$ yr. Other periods are termed intermediate.

Except for the work of Triebwasser *et al.*[9], the dates of the manuscripts are used as "first approximations" to the dates of measurements. The delay time may even be physically justifiable to some extent; Sheldon's model suggests that the appearance of sunspots would be delayed considerably with respect to the production of neutrinos.

Table 1 presents the values of d for which the total standard deviation $\sigma=(\sigma_{\rm exp}^2+\sigma_{\rm th}^2)^{\frac{1}{2}}$ is less than 900 p.p.m. In the weighted means $\bar{d}$, in which the weights are σ^{-2}, a measurement d with σ larger than 900 p.p.m. would be neglected in any case. The result of Robiscoe and Cosens[12], which is in an intermediate period, is based on two measurements of which the former was carried out during a quiet period. This complication is not important because the former measurement would not change the value of $\bar{d}$ significantly in either period.

The number of useful observations is very small, and there is only a single measurement to determine the value of $\bar{d}$ for the intermediate periods. The situation is not much better in the active and quiet periods. Only one active

Table 1. COMPILATION OF DATA

* Date of the manuscript. † Private communication reported in ref. 16.

period is covered by the measurements. Some preliminary conclusions can be drawn nevertheless. First, the values of d obtained from a_e (and a_μ) agree with the values of d obtained from $S(2,1)$ for similar periods. This supports the hypothesis of proportionality already presented. Second, the results comply with the 11 year variation, irrespective of whether $S(2,1)$, a_e, and a_μ are considered separately or together. Thus, if the best results on $S(2,1)$ (refs. 9, 12 and 14) are compared with each other, $S(2,1)$ is found to increase with increasing solar activity. The two good results on a_e (refs. 10 and 13) also comply with the prediction. Because of the large weights of these good measurements, the values of $\bar{d}$ also show the 11 year variation.

There is serious disagreement with the predictions in the "indirect" determinations of $S(2,Z)$ from the measurements of $\Delta E - S(2,Z)$ (spacing $2P_{3/2}$–$2S_{1/2}$). The corresponding values of $S(2,Z)$ disagree with the theoretical values and with the two recent good experimental values[12,14], whether the hypothesis of the time variation is true or not. This suggests that the indirect measurements contain an unknown error.

In spite of the suggestive agreement between the predictions and the observations, only new experimental data can settle the problem. If the values of d, especially for a_e, become negative during 1974–77, the 11 year variation of the radiative corrections would be proved. If the opposite occurs, this particular variation would be ruled out, but other kinds of time variation could still exist.

The Free Dynamics of Pulsars

THE rotational dynamics of freely spinning pulsars are discussed below; the effect of pulsar nonrigidity and some possible consequences of viscosity are included. Expressions given for the period of the Eulerian free oscillation (or free precession) of pulsars are of particular interest. This oscillation is a permitted solution of the free rotational dynamics because, as a result of centrifugal effects, pulsars are somewhat oblate, and any nonspherically symmetric body, which is not a perfect fluid and is spinning freely in space, will wobble about the constant direction of its angular momentum vector. It will be mentioned that this phenomenon may account for some of the amplitude and time variations seen in pulsar signals and, if observed, could give the first fairly accurate measurement of a pulsar's size.

Other articles[1–4] have already discussed the rotational dynamics of pulsars under the action of torques caused by the electromagnetic forces present; they have looked into the alignment of the magnetic dipole in the oblique rotator model and the decay of the spin itself which indicates the pulsar age. The work presented here will supplement these calculations by presenting the solutions to the homogeneous equations of motion and, because the actual torques are so weak, will more clearly represent a pulsar's rotational motion over a short time. The free motion of pulsars has previously been discussed[5,6] but only in quite different contexts. Several researchers[7–9] have recently discussed similar problems.

The equilibrium shape of a homogeneous, freely rotating fluid body is, in general, that of a MacLaurin spheroid for slow rotations[10]. The spheroid's flattening $f \equiv (c-a)/a$, where c and a are, respectively, the polar radius and equatorial radius of the body) is a unique function of the parameter $\omega^2/2\pi\rho$, in which ω is the body's spin frequency and ρ its density. In the case of nonhomogeneous bodies with a given initial density distribution, a series solution can be found[11] giving f as a function of a nondimensional surface acceleration

$m = \omega^2 a/g_e$ where g_e is the gravitational acceleration at the equator $r = a$. This solution shows that to $0(f^2)$, f lies between $m/2$ and $5m/4$ where the lower bound corresponds to a hypothetical case in which all the mass is concentrated at $r = 0$ and the upper bound represents the exact solution for a homogeneous body.

Thus, assuming that over long periods of time pulsars react like fluids and ignoring any deformation caused by magnetic effects (because it will be relatively small[7-9] for expected values of the magnetic field),

$$f \sim m = \omega^2 a/g_e = 4\pi^2 a^3/(GMP^2) \quad (1)$$

where P is the pulsar's spin period, assumed to be the period of its signal, and M is its mass; G is the universal gravitational constant. For typical models of the Crab pulsar NP 0532, equation (1) gives $m \sim 10^{-3}$.

Before considering the effects of fluidity and viscosity, we discuss the motion of a rotationally symmetric rigid body which is spinning freely. The solution[12,13] of the Euler equations shows that such a body (and its attached coordinate system) has a constant angular velocity about its symmetry axis z while the vector $\omega_x \mathbf{i} + \omega_y \mathbf{j}$ is of constant magnitude and precesses uniformly about z with the Eulerian free oscillation period

$$P_e = 2\pi I/(\omega_z \Delta I) = (I/\Delta I)P \quad (2)$$

where I is the moment of inertia about any axis lying in the equatorial plane and $(I + \Delta I)$ is the moment of inertia about the z axis. Thus a free body rotates or wobbles about the direction of its constant angular momentum vector with a constant amplitude if there is no energy dissipation.

For the slightly distorted shape of an ellipsoid[10]

$$\Delta I/I = 1/2[1 - (c/a)^2] \sim f \quad (3)$$

The effect of nonrigidity is to lengthen the Eulerian free precession period[11,14,15] while leaving unchanged the qualitative picture of the dynamics. This occurs because any portion of the rotational bulge which is able to follow the instantaneous rotation axis will not affect the free precession; for instance, in the limiting case of a rotating perfect fluid, no precession will occur for ω will always be aligned along the principal axis. Quantitatively, the Eulerian free oscillation period, given by equation (2), is replaced for a nonrigid body by[11,15]

$$P'_e = (2\pi/\omega_z)\left(\frac{A + k\omega_z^2 a^5/3G}{C - A - k\omega_z^2 a^5/3G}\right) \quad (4)$$

where k is the Love number which specifies the fractional disturbance of the surface potential due to a second degree tidal potential. We may calculate k for a particular body, and for an incompressible homogeneous sphere it is $3/2(1 + \mu)$ in terms of the nondimensional rigidity $\mu = 19\bar{\mu}/(2\rho g_e a)$ with $\bar{\mu}$ the rigidity and ρ the density[15].

Ruderman[16] has shown that the outer layers of neutron stars will cool very rapidly by neutrino emission processes to form an outer crust which will be relatively thick for all but the most massive neutron stars. The crust is comprised of nuclei arranged into a body centred cubic lattice. This knowledge permits an estimate[17] of the crustal rigidity: $\bar{\mu} \sim 10^{30}$ dynes cm^{-2}. Thus for NP 0532, $\mu \sim 10^{-3}$, which indicates that the pulsar surface, although extraordinarily strong by terrestrial standards, behaves much like a fluid in the presence of the pulsar's enormous gravitational field. Considering $\mu \ll 1$ and assuming the pulsar superfluid core to have a negligible effect, we find $P'_e = r^{-1} P_e$ and thus the free precession period would be increased substantially by the fluidlike character of the crust.

Equation (4) assumes an inviscid body, but for completeness we must ask whether viscous effects can prevent the body from acting like a fluid and cause it to maintain its rigid configuration. This can happen only if frictional forces dominate the inertial forces, that is, if the Reynolds number $2\pi a^2/\mu\omega_z \nu \ll 1$ with ν the kinematic viscosity. For a typical pulsar this requires $\nu \gg 10^{14}$ cm^2 s^{-1}. Unfortunately, little information is available on neutron star viscosities beyond an estimate[16] of the viscosity of the inner core. More is known about the terrestrial solids; for instance, $\nu \sim 10^{13}$ cm^2 s^{-1} for glacial ice and the value for the Earth's mantle is $\sim 10^{22}$ cm^2 s^{-1} (see ref. 11). If the crust's viscosity is large (or if there is a very strong magnetic field[18]), the pulsar will respond as though it is a rigid body for the high frequency spin and precession motions. In this case the solution (2) is once again valid; in analogy with the simple mass spring dashpot system, there is little time delay in the response of the body and little energy dissipation. The intermediate case of $\nu \sim 10^{14}$ cm^2 s^{-1} will have large energy dissipation but the dynamics are too difficult for discussion here.

From equations (2) and (3), we see that the body axes system for a slightly distorted viscous spheroid precesses with a period

$$P_e = f^{-1} P \sim m^{-1} P$$

or about 10 s for the Crab pulsar. In the inviscid case ($\nu \ll 10^{14}$ cm^2 s^{-1}), equation (4) gives $P'_e \sim (m\mu)^{-1} P$ or several hours for the Crab pulsar if the asphericity is determined solely by rotation.

It is not possible to specify the amplitude of the Eulerian oscillation without knowing initial conditions from which to derive the constants of energy and angular momentum; however, the amplitude is known to be small in the case of the Chandler wobble of the Earth. Whatever the initial amplitude, it will decay in time because of viscous dissipation and electromagnetic torques and, if this oscillation is to be significant, there must be an impulsive energy input from time to time. This same argument has been used in the case of the Earth; it is difficult to understand why the Earth's axis should wobble at all[15], but recent evidence[19] suggests that earthquakes may be the energy source for the Earth's wobble. It is therefore of some interest that the abrupt jumps $\Delta\omega$ in frequency observed in several pulsars (for example, NP 0532 and PSR 0833) have been explained in terms of starquakes which decrease the pulsar's moment of inertia and thereby cause ω to increase so that angular momentum is conserved. In fact, starquakes can be thought of as being generated as the pulsar attempts to go from an oblate shape to a more spherical one because of the slowing spin velocity[17,20]. Recently Ruderman[6] published an extension of his idea on starquakes in which he discusses the very low frequency wobble of the Crab pulsar as being a result of precessional motion and tries to relate changes in the wobble period after the starquake with changes in the moment of inertia caused by the starquake. During the discussion, he assumes that the pulsar's shape responds immediately to any change in the rotation axis.

Whatever the mechanism causing the frequency jumps, the spin rotational kinetic energy E is increased by an amount $\Delta E \sim (\Delta\omega/\omega)E$. If energy of the same order of magnitude is put into the precessional mode, large amplitudes are possible for the precessional motion. The amplitudes seen, however, may be just a remnant of the initial condition; the precessional decay rate should not be too dissimilar from the spin decay rate.

Our picture of the rotating neutron star, as seen over the short period when the weak torques can be neglected, is a body whose angular momentum vector is constant from an external point of view. It is, however, a picture in which the magnetic moment axis (which may be considered as piercing the surface at a fixed point) appears to wobble in space because of the combined motions of spin and precession. This wobble can produce time variations in the signal period, as has already been described by Ruderman[6].

The wobbling will also permit the emissions from a narrow angular source on the pulsar to sweep out a larger angular area of the sky during one precession period. This will increase the probability of seeing any pulsar which has a narrow emission cone, and the pulsar number density may be less than is currently thought by those who believe the emission is beamed. Correspondingly, because the amplitude of the received signals from such a pulsar will depend on the portion of the emitting region seen, the signals will be modulated according to the orientation of the magnetic axis relative to the spin axis and the magnitude of the precession angle. This modulation may account for part of the amplitude variations[21] seen in pulsar signals. The period of this modulation will be P_e (or P'_e); modulations of pulsar signals have been sought[22,23] but only at much shorter periods.

Even if the amplitude of this precession is small, it may be of considerable interest if its period is measurable. If a period of modulation can be obtained, we can reverse the procedure described above for f is expected to be very small. Thus, because $m \sim f$, we have a measure of the nondimensional surface acceleration as given in equation (1). Using this, we can write the pulsar radius as

$$a = [GM/4\pi^2 P_e]^{1/3} P$$

for the viscous case where everything is known except M, which, according to current models, must be near one solar mass. In this way, a pulsar radius could be measured for the first time. This result should be useful as a constraint on future neutron star models.

I thank R. H. Rand for reading the manuscript.

Electron Intensity Variations in the Inner Belt following a Geomagnetic Storm

Loss characteristics of inner belt electrons have been studied since the Starfish and USSR nuclear explosions in the upper atmosphere in 1962[1-3]. The solar flares of September 2, 1966, and May 23, 1967, were the first natural events to increase the electron population above the artificial level[4,5]. We have studied the electron flux levels following the May 1967 event for a three month period starting in August 1967. Electron flux levels above 120 keV were monitored by ionization chambers also used as solar X-ray monitors on OGO IV in polar orbit. Supplementary electron data above 280 keV were obtained from the C1 detector on the 1963 38C satellite also in polar orbit. Details of the 1963 38C detectors have been described previously[1].

Table 1. OGO IV IONIZATION CHAMBER CHARACTERISTICS

Detector	D1	D2
Window thickness (mg cm^{-2} of beryllium)	243	23·5
Chamber gas effective thickness (mg cm^{-2})	18·9	4·52
Geometric factor (cm^2 sterad)	0·42	0·35
Field of view	±8·8°	±8·8°
Electron cutoff energy for chamber window (keV)*	550	120
Proton cutoff energy for chamber window (MeV)†	12·5	3·5

* 10 per cent of maximum response.
† Theoretically determined range (experimentally verified to within 1 MeV).

Two OGO IV ionization chambers provided night-time particle data in the region of the South Atlantic Anomaly. The ionization chambers are identical except for window thickness[6,7] and have been calibrated for proton and electron response[8] (Table 1). In addition to the ionization current induced by electrons and protons penetrating the chamber windows, some ionization current is produced by high energy protons (> 40 MeV) which penetrate the 0·25 cm stainless steel chamber walls. Proton flux data[9] which were time invariant over the period of interest[10] indicate that more than 80 per cent of the D1 ion current may be attributed to penetrating protons and can be used as a proton background monitor for the D2 chamber. The D2 ionization current is dominated by low energy electrons (> 120 keV) passing through the chamber window. Low energy protons passing through the windows

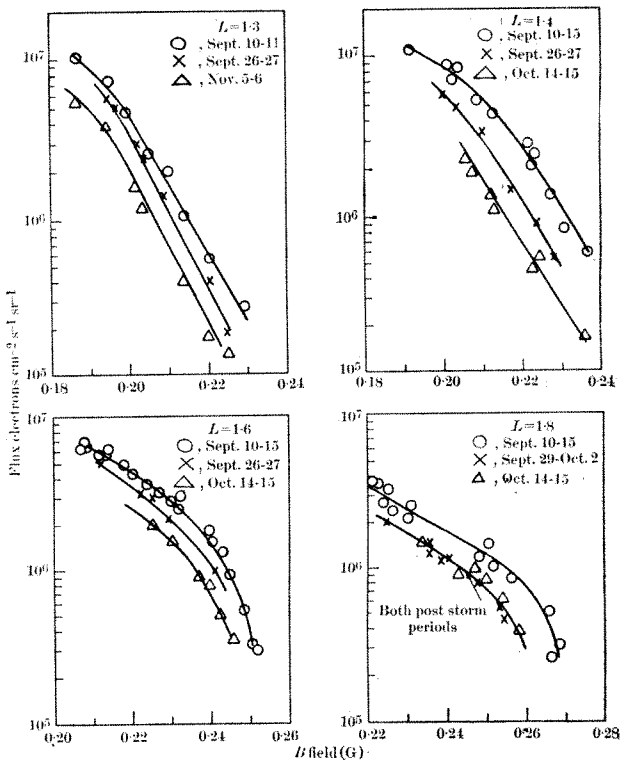

Fig. 1. D2 electron flux against mirroring field at selected L shells. Each curve is fitted to data of the three selected time intervals except at $L = 1{\cdot}8$ where no significant difference appeared between the flux at the two selected post storm periods.

of either chamber do not make a significant contribution to the ionization currents observed[11].

OGO IV data cover L shells from 1·3 to 1·8 and B fields from 0·18 to 0·25 G. Somewhat smaller fields were covered by 1963 38C due to its higher orbit. The OGO IV ionization chamber look direction was established by reference to the orbital plane experiment platform. Data were taken only when the detectors were oriented within $\pm 10°$ to the normal plane of the local field, as determined by the forty-eight coefficient field model of Jensen and Cain. The field value at which the particles would mirror was obtained by using the adiabatic invariance of the electron magnetic moment.

A check on the field value computed by the Jensen and Cain model was provided by the D1 chamber sensitive to omnidirectional protons. Plots of D1 current against field were made using data over the 3 month observation period and a least squares fit established a nominal relationship between the field and the D1 current for each L shell. At $L = 1·3$ the standard deviation was $\pm 0·002$ G over the field range considered here. At $L = 1·8$ the deviation was $\pm 0·006$ G with somewhat smaller errors at intermediate L shells. Since the D1 and D2 currents were observed simultaneously, the Jensen and Cain field was corrected by using the nominal field value corresponding to the D1 current on that L shell. This method prevents errors in the field values which may be a function of altitude and hence a function of time.

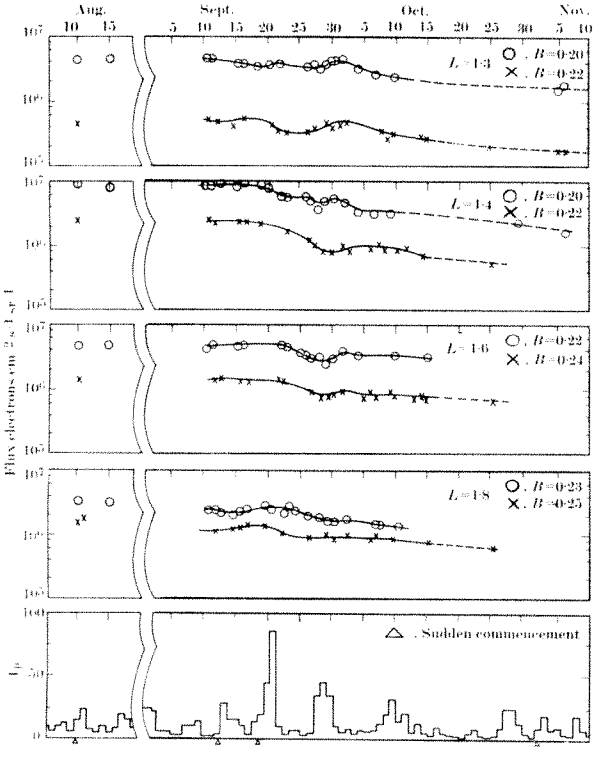

Fig. 2. Daily averages of D2 flux over the two month period during which significant variations occurred. The data shown are selected from mirror fields $\pm 0·005$ G given from the field values to which the data were normalized. The index A_p is also shown.

The electrons mirroring at field values reported here remain above 350 km as they drift eastward through the Anomaly. Previous work[12,13] indicates that no significant losses should occur due to atmospheric scattering. OGO IV electron data (> 120 keV) obtained on both sides of the Anomaly did not indicate any electron loss above 350 km.

Solar activity was considerable during late May 1967. The 3B flare of May 23 seems to be associated with the geomagnetic storm of May 26 ($A_p = 146$). Between June 6 and September 19, 1967, the A_p daily index remained below 29. The September 21 storm ($A_p = 85$) seems to be associated with two 2B flares occurring 3 days before. A smaller disturbance occurred on September 29 with $A_p = 45$.

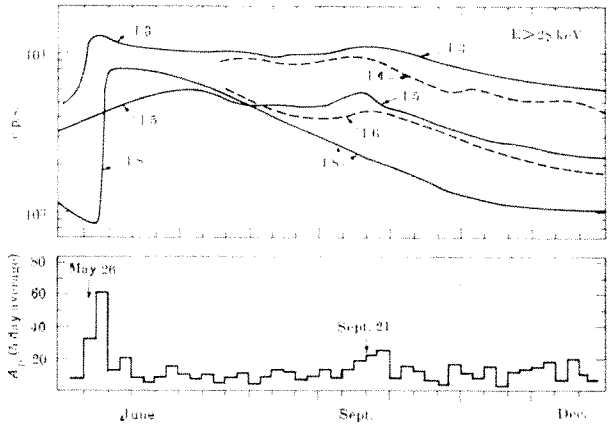

Fig. 3. C1 data from 1963 38C taken from refs. 5 and 10. The curves shown represent a best fit to the ten day average flux values. The mirror field ranges from which the data have been selected are also shown along with the five day average values of A_p.

L shell	B range
1·3	0·165–0·175
1·4	0·180–0·190
1·5	0·190–0·200
1·6	0·195–0·205
1·8	0·200–0·210

Each plot in Fig. 1 indicates the flux variation with the mirroring field for electrons on a given L shell at the specified time observed with the D2 chamber on OGO IV. Most striking is the rapid change in the electron flux following the September 21 storm. Largest decreases occur at the largest fields for which data are available, particularly at $L = 1·3$ and 1·4. Decreases are generally smaller at larger L shells but not as confined to the region near the loss cone. Twenty-five days following the storm the flux had decreased on all L shells and fields covered by OGO IV.

The field dependence of the flux is removed in Fig. 2 by making plots similar to those shown in Fig. 1 for short time periods over which the flux variation is not significant. Using the derived flux field relationship appropriate to the time period, the flux is normalized to one of the two field values indicated for each L shell. Only data requiring a correction of less than 0·005 G are used in these plots. The largest response to the September 21 event is at $L = 1·4$ and $B = 0·22$ G where the flux is reduced to one-third of its initial value in 8 days. At $L = 1·8$ a small fluctuation coincident with the September 21 events occurs; it does not, however, cause a significant change in the general decay rate observed for this L shell before the storm. In addition to the general flux decrease following the September 21 event, the effects of a smaller storm on September 28 are also observable. The electron population seems to respond more rapidly to this second storm, particularly at weaker fields.

Fig. 3 indicates the C1 detector data on 1963 38C for the time period of interest[10]. The data for each L shell are the 10 day average for electrons mirroring within the range of field values specified. For $L < 1·6$ the decay in the electron flux (> 280 keV), initiated after the large increase in May, had ceased before September 1967. A modest increase, particularly at $L = 1·5$, is observed. The uniform decay, observed in the OGO IV data at lower energies, seems to initiate in late September and continue for at least 3 months. The flux at $L > 1·7$ seems to be unaffected by the September event at the weaker fields and

higher energies covered by 1963 38C. This marked difference in response to the September event is also observable in the OGO IV data. The 1963 38C data do not have adequate time resolution to associate the decay observed by the C1 detector with the September 21 event except at $L = 1{\cdot}5$ where the flux was reduced by more than a factor of two in the ten day period following September 21.

Until recently, short term electron population decay characteristics had only been studied in the inner belt following the high altitude nuclear bursts in 1962. Van Allen's[3] measurements at $L < 1{\cdot}5$ indicate that 0·5 MeV electrons mirroring at large B fields decayed more rapidly than equatorially mirroring electrons. This is consistent with the trend reported here.

The May 23, 1967, flare and subsequent geomagnetic storm are relevant to the observations reported here. This solar event caused an observable increase in the trapped electron flux for $E > 280$ keV over the entire inner belt[9]. The May 1967 increase was large and well defined for $L > 2{\cdot}0$ and $L < 1{\cdot}4$. At $L = 1{\cdot}5$ the data of Bostrom *et al.*[5] indicate the $E > 280$ keV flux required more than 30 days to reach maximum value. It would seem that those L shells which responded slowly to the initial particle population increase were most strongly affected by the September event.

For electrons mirroring at latitudes appreciably off the geomagnetic equator, the flux levels in the inner belt seem not to be characterized by simple decays from the one or two large events which cause major increases in the inner belt each year. Detailed consideration must be given to the smaller geomagnetic events subsequent to the major storms for a proper description of the temporal variations of electrons mirroring at intermediate latitudes in the inner belt.

Extrapolation of the Shear Elastic Moduli of Face Centred Cubic Solids to the Molten State

The principal characteristic of liquids is their zero elastic resistance to shear. The change in the shear elastic moduli of solids near their melting point is therefore of some interest in connexion with the process of melting. The data available[1] show that the elastic stiffness in general decreases with temperature, but does not reach zero at the melting point. It seemed that a more informative way of treating the data than plotting the moduli against temperature might be to plot them as functions of the volume (at constant pressure). When this was done it was found that the points fell very nearly on a straight line, and it became clear that in the case of close packed solids where the structure of the melt is known to be similar to that of the solid it would be possible to obtain an estimate of the shear modulus of the melt by extrapolating this line to the volume of the melt.

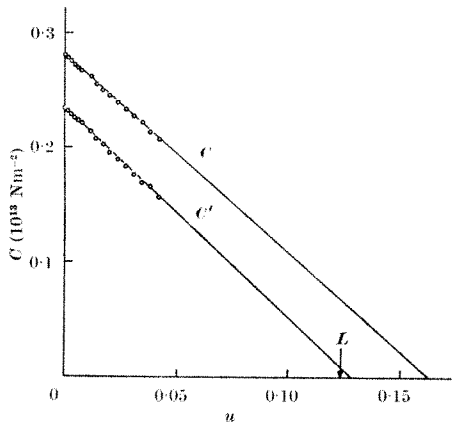

Fig. 1. The shear elastic moduli of aluminium plotted against u, the fractional increase in volume (relative to 0° C). The arrow at L indicates the value of u for the melt.

This procedure was first tried for aluminium for which values of the shear moduli C ($= c44$) and C' ($= (c_{11} - c_{12})/2$) are available nearly to the melting point[2]. In Fig. 1 these are plotted against values of $u (= (v - v_0)/v_0)$, where v is the specific volume at a given temperature, and v_0 is the specific volume at a convenient reference temperature, usually 0° C. It will be seen that the experimental values lie on straight lines and that when extrapolated the line for C' falls to zero very near the value of u corresponding to the melt. The line for C reaches zero at a higher value of u.

For most other f.c.c. melts elastic data were only available over the range 0–300 K so that the data had to be extrapolated over a much wider gap. For lead some data have recently been obtained between 0° and 120° C (ref. 3) and these have been used together with the earlier values[4] to give similar results to those obtained for aluminium.

Table 1

Element	Value of u at which the shear modulus becomes zero on extrapolation	Value of u for the melt
Al	0·125	0·123
Cu	0·113	0·127
Ag	0·110 ($C' = 0$)	0·127 (ref. 7)
Au	0·114	0·117
Pb	0·059	0·064
A	0·215 ($C = 0$) 0·245 ($C' = 0$)	0·243 (ref. 9)

The values for copper[5], silver and gold[6] have been treated in the same way, but owing to the wide extrapolation involved must be treated with some reserve. In Table 1, the value of u for which the linear extrapolation of the shear modulus reaches zero is compared with the value for the melt[7].

The recent measurements of the elastic moduli of solid argon[8] enable us to apply the same method of plotting the shear moduli to this case. We now take the reference temperature as 0 K and using the volume data of Dobbs and Jones[9] we obtain the plots shown in Fig. 2. These show a pronounced curvature especially at the low temperature end of the curve. Linear extrapolation of the high temperature parts of the curves for both C and C', however, leads to zero values in the region of the value

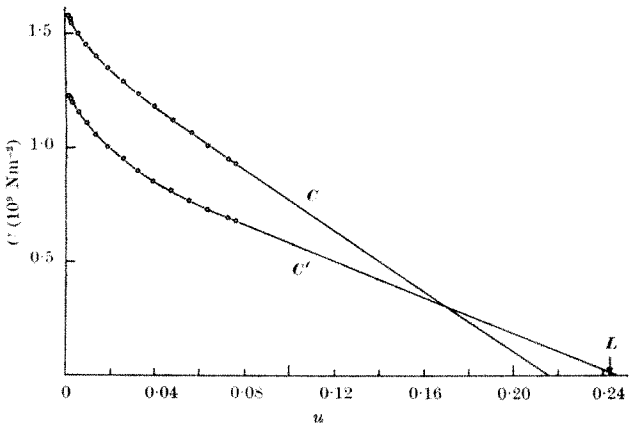

Fig. 2. The shear elastic moduli of argon plotted against u, the fractional increase in volume (relative to 0 K). The arrow at L indicates the value of u for liquid argon.

of u for the liquid, though in this case C reaches zero at a slightly smaller value of u.

The errors in the values of u were estimated by comparing independent estimates. The figures in the third column were taken from the review article by Borelius[7]. The main uncertainty comes from the expansion on melting. Comparison of the figures in the literature suggests that an error of about 0·01 in the values in column 3 would be reasonable. The figures in column 2 were obtained from several estimates using different treatments of the expansion data. These varied by about 0·005. It seems therefore that differences between column 2 and column 3 are not significant, but the correlation between the two sets of values near 0·06 (Pb), 0·12 (Al, Cu, Ag, Au) and 0·24 (A) is significant.

These results suggest that the zero value of the shear modulus of liquids is a consequence of their low density. In other words, if the atoms of the liquid were to be placed on an f.c.c. lattice at the same density they would form a "solid" of zero shear modulus.

It would be of interest to test this suggestion by further studies of the high temperature variation of the elastic contents, and it would also be important to extend these measurements to high pressures.

BIOLOGICAL SCIENCES

N-Terminal Sequences of Immunoglobulin Heavy and Light Chains from Three Species of Lower Vertebrates

It has been established that immunoglobulin heavy (H) and light (L) chains have a variable amino terminal region of about 110–120 residues[1–9]. This region presumably makes up the antibody binding site and is responsible for the high degree of antigenic specificity that is a characteristic feature of these molecules. In spite of the growing body of amino-acid sequence data on immunoglobulin H and L chains, the genetic mechanisms by which an almost infinite array of specific antibodies can be expressed in response to antigenic stimulation remain to be established. It has been proposed, as one possible explanation, that the genes coding for the immunoglobulin polypeptide chains, are present in the germ line[10–11]. This study was prompted by this concept, as well as the structural similarities that have been demonstrated among various H and L chains, suggesting that genes coding for these chains evolved from a common ancestral gene[12,13]. We have investigated immunoglobulins from three lower vertebrates in the hope that sequence data of the variable region of these chains will provide an insight into the genetic mechanisms responsible for antibody variability.

For these studies antibodies were isolated against *Salmonella typhosa* "O" antigen from three species of animals; an amphibian, the marine toad (*Bufo marinus*), two types of bony fish, the paddlefish (*Polyodon spathula*) —a chondrostean representative—and the gar (*Lepisosteus osseus*)—representing the holosteans. Purification of the immunoglobulins was achieved by a combination of chloroform : methanol extraction, ion exchange chromatography and gel filtration. Antibody activity was followed throughout the purification process. The homogeneity of the purified material was established in each preparation by immunoelectrophoresis and ultracentrifugation.

For further studies the isolated immunoglobulins from each species were totally reduced and alkylated in 7 M guanidine–HCl and the H and L polypeptide chains separated by gel filtration on 'Sephadex G-200' columns in the presence of 5 M guanidine–HCl. The isolated H and L chains were homogeneous on electrophoresis in acrylamide gel containing 5 M urea.

Table 1. COMPARISON OF PHYSICAL AND CHEMICAL PROPERTIES

Species	$s^{\circ}_{20,w} \times 10^{-13}$	Mol. wt.	Percentage carbohydrate	Chain mol. wt. H	Chain mol. wt. L
Marine toad	17·9	850,000	9	72,000	23,000
Marine toad*	7·3	173,000	n.d.	63,000	23,000
Paddlefish	14·2	630,000	7	72,000	23,000
Gar	13·6	600,000	9	72,000	23,000

* Low molecular weight antibody.

In Table 1 some of the physical and chemical studies of these molecules are compared. From the marine toad, two types of immunoglobulins were isolated: a macroglobulin resembling mammalian IgM in molecular weight, carbohydrate content and chain molecular weight, and a low molecular weight antibody which cannot be equated with a mammalian class of immunoglobulin[14]. The amino-acid composition, peptide maps and antigenic analysis revealed that the two types of antibodies in the marine toad represented distinct classes.

The paddlefish and gar were found to contain macroglobulins that were significantly lower in molecular weight than that found in the marine toad. These molecules did, however, have H and L chains of the same size as in the macroglobulin of the marine toad. Preliminary evidence indicates that these molecules have a tetrameric molecular form similar to the macroglobulins recently isolated from another bony fish, the carp (*Cyprinus carpino*), by Shelton and Smith[15]. This is in contrast to the pentameric configuration common to man, rabbit, mouse, sheep, chicken and dogfish shark[16–18].

The amino-acid compositions of the macroglobulin H and L chains from all three species closely resembled each other and are very similar to human IgM[19]. This is especially evident in the number of methionine and cystine residues and a high content of serine, threonine and acidic amino-acid residues which seems to be a characteristic feature of all these macroglobulins.

N-terminal sequence analyses of the isolated H and L chains were carried out by the Edman degradation method as described by Waterfield and Haber[20]. These analyses are shown in Table 2. The L chains from all the species examined as well as the H chain from the marine toad low molecular weight antibody were found to be non-reactive in the Edman procedure. We have assumed that the amino terminal residue is pyrrolidonecarboxylic acid (PCA), which has been found at the N-terminus of most H chains and also the lambda type L chain from mammalian immunoglobulins[1-9,21,22]. The blocked H and L chains of the marine toad low molecular weight antibody and the paddlefish macroglobulin L chain were digested with pronase and the blocked N-terminal pronase peptides from each of the chains were isolated from a 'Dowex 50–X2' column as described by Bennett[22]. The results in Table 2 are suggested sequences for these blocked N-terminal peptides based on amino-acid compositions of the principal peptides deduced from molar yields. It is possible in this case that other blocked N-terminal peptides are present in much lower yields. The H chains from all three species of macroglobulins had a free N-terminal residue. The yield of the residues on a relative molar basis indicates that the sequence shown for each of these chains represents its principal N-terminal sequence.

Table 2. COMPARISON OF AMINO TERMINAL SEQUENCES

Source	Chain type	Residue position 1	2	3	4	5	6	7

The amino terminal residue was nonreactive in the Edman procedure and we have therefore assumed the presence of pyrrolidonecarboxylic acid.

Even the limited sequence data reported here suggest a degree of homology among these chains, as well as homology to immunoglobulin chains from mammals. These data are similar to those reported for human mu and lambda chains and for rabbit gamma chains[21-23]. The sequences of the paddlefish and gar H chain seem to be very similar to those of the leopard shark and rabbit L chain sequences[24,25]. It is also of interest relative to our H chain data that a free N-terminal residue of glutamic acid has been reported from a few mu, gamma and alpha heavy chains of man[8,9]. Such similarities provide additional evidence that immunoglobulin H and L chains had a common evolutionary origin.

We thank Dr Harry K. Dupree, Dr William Niedermeier and Thomas H. Russell for collaboration and Drs Ralph Schrohenloher and Ahmed Habeeb for discussion. This work was supported by grants from the NIH, NSF and John A. Hartford Foundation.

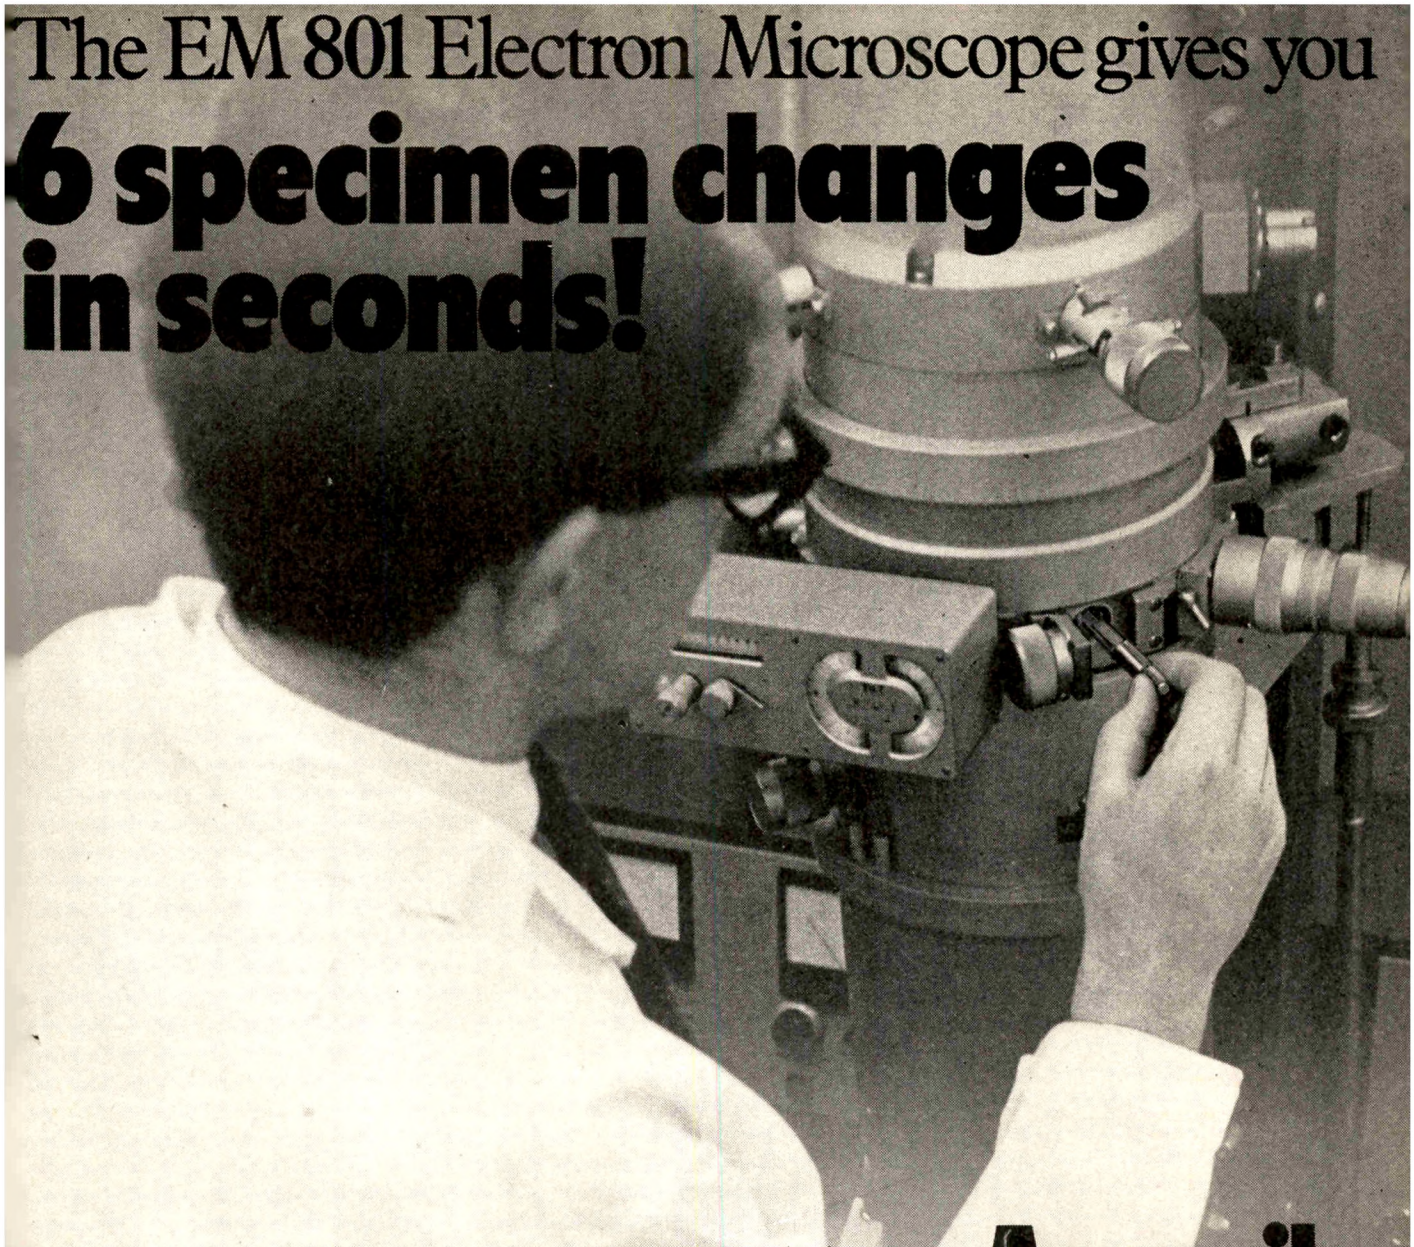
Very Lysine Rich Histone of Echinoderms and Molluscs

THE similarity of the histone component F2a1 from calf and pea[1] casts doubt on the hypothesis that it acts as a selective repressor of gene activity. Such a function may, however, be fulfilled by the very lysine-rich fractions F1 because they are significantly heterogeneous in vertebrate species[2,3]. Alternatively, the heterogeneity might be explained in terms of gene multiplicity and/or a modification of some amino-acid residues[4] and may have no implication in gene regulation. It would then have an evolutionary significance, similar to that of the heterogeneity in proteins such as haemoglobin and cytochrome. We thought that it would be of interest, therefore, to study the very lysine-rich component in different species, particularly those far apart on the evolutionary scale. We chose a mollusc and an echinoderm and found that their F1 histones differed from each other in a limited but significant way and that they also differed from the equivalent F1 fraction from calf thymus.



We obtained the nuclei by homogenizing and centrifuging the tissue in 0·25 M sucrose–3 mM $CaCl_2$. In some cases purer nuclei were obtained using 2 M sucrose–3 mM $CaCl_2$–0·5 per cent 'Triton X 100'. They were washed with 0·1 M Tris buffer (*p*H 7·6–8·0) and with 0·15 M NaCl. Sodium bisulphite was also used to minimize proteolytic degradation[5].

We prepared histone fractions by the methods described by Johns[6]. We encountered difficulties when applying these methods to invertebrate tissues; in particular it was difficult to prepare fraction F2b from echinoderms. Fractions F2a and F3 were very similar to the analogous fractions from calf thymus. The fraction F1 used in these studies was isolated by method 1 in the case of the sea urchin embryos and the mollusc hepatopancreas. Method 2 was found more suitable in the experiments with the sea cucumber.

The very lysine-rich fraction was prepared from the haemal system of the sea cucumber *Holothuria tubulosa* (mainly a myoepithelial tissue), *Arbacia lixula* embryos at the late blastula stage and hepatopancreas from the

mollusc *Mytilus edulis*. The amino-acid analyses of the fractions are given in Table 1. Comparison with the data for calf thymus histones reveals an analogy in the relatively high amounts of lysine and alanine and the low content of arginine of this protein. A significant difference is found, however, in the amount of proline, an amino-acid of great structural importance. This difference is most prominent in the echinoderm histones; the mollusc histone has an intermediate proline content. From the values shown in Table 1 it can be concluded that at least 10 per cent of the amino-acids of this protein are different in calf and the echinoderms studied. Furthermore, Fig. 1 shows that the electrophoretic mobility of this fraction is similar in the three cases studied and higher than in calf thymus. These differences seem to be more marked than those found in this component in calf and pea[7]. The results show that the very lysine-rich histones vary significantly in different invertebrates and that the variation is much greater than that reported for other histones. Evidently the structural requirements for the biological activity of this fraction are not so stringent as those for the histone fraction F2a1.

Ser	6·4	4·4	4·7	8·0
Pro	9·7	5·9	5·7	7·5
Gly	7·4	6·5	4·7	7·0
Ala	23·3	22·1	21·9	20·0
Met	0·0	0·1	0·4	0·5
Val	4·5	4·1	2·8	3·8
Ile	0·9	3·1	2·9	2·8
Leu	4·0	3·6	4·2	3·6
Tyr	0·6	0·7	1·0	1·2
Phe	0·7	1·2	0·8	1·6

An amino-acid analyser (Unichrom, Beckman) was used in the analyses. No corrections have been made for hydrolytic losses. The amino-acid compositions are expressed as moles/100 moles of all amino-acids found. The analysis of calf thymus F1 is reproduced from Kinkade and Cole[8]. All the analyses are average values obtained from two or more fractions prepared in different operations. Independent analyses coincide within experimental error. The fraction obtained from *H. tubulosa* was purified by reprecipitation with three volumes of acetone.

This research was supported in part by the US National Institutes of Health. We thank Miss J. Colom for the amino-acid analyses and Mr A. Jimeno for technical assistance.

Ribosomal RNA Synthesis and RNA Polymerase

MULTIPLE forms of RNA polymerase activity have been isolated from developing sea-urchin embryos, rat liver nuclei and calf thymus[1–3]. The molecular basis of this heterogeneity is at present unknown but, whatever its basis, the crucial question seems to be whether different enzymes copy different genes. We report here the isolation and purification of two different RNA polymerases from *Xenopus* oocytes; only one of them is localized in the nucleolus. On the basis of localization, binding to ribosomal DNA, and response to inhibitors, we conclude that the nucleolar RNA polymerase is responsible for ribosomal RNA synthesis *in vivo*.

We report also the effect of α-amanitin on the RNA synthesis stimulated by microinjecting *Escherichia coli* σ factor in stage 4 oocytes and in early cleavage embryos. In normal conditions, the first class of cells produces almost exclusively ribosomal RNA; but the second does not produce ribosomal RNA at all. Our results suggest that in stage 4 oocytes as well as in early cleavage embryos both polymerases are present, even if only one of them is producing measurable amounts of RNA.

Xenopus laevis offers a great advantage for studying RNA polymerases from higher organisms because pure ribosomal DNA can be isolated in large quantities[4]. This DNA[5,17] comprises repetitive units, each consisting

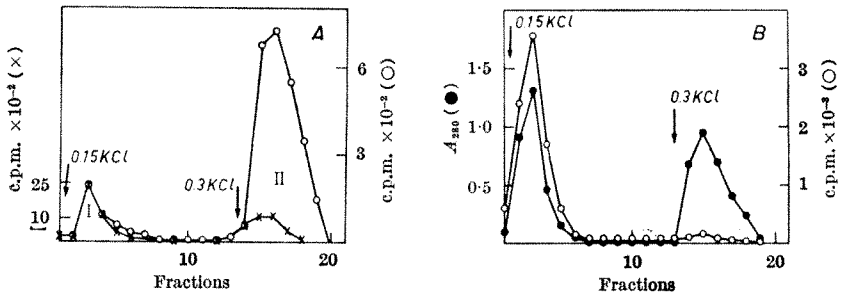

Fig. 1. DEAE-cellulose chromatography of *Xenopus laevis* RNA polymerase Tissues were homogenized at 4° C in 4 volumes of buffer containing 10^{-3} M Tris (*p*H 7·9) and $1·4 \times 10^{-3}$ M β-mercaptoethanol and the homogenate was centrifuged at low speed after filtration through cheese-cloth. Chromatin was precipitated by increasing the ionic strength to 0·1 M KCl and the precipitate was collected by centrifugation at high speed. RNA polymerase activity was solubilized by sonication in 0·75 M KCl and the subsequent steps involved reduction of the ionic strength to 0·125 M and chromatin removed by centrifugation for 1 h at 15,000 r.p.m.. DEAE-cellulose was equilibrated with 10^{-3} M Tris (*p*H 7·9) and $1·4 \times 10^{-3}$ M β-MSH. The chromatin eluate was applied to the column and after washing with standard Tris-MSH buffer the ionic strength was raised to 0·15 M KCl. The subsequent step elution was at 0·3 M KCl. The fractions were assayed for incorporation activity (○—○) and the assay mixture (0·3 ml.) contained, per ml., 100 μmoles Tris-HCl (*p*H 7·9), 3 μmoles $MnCl_2$, 1·8 μmoles ATP, GTP and CTP, 2·5 μCi ^{14}C-UTP (395 mCi/mmole), 0·526 mg phosphoenolpyruvate, 8·8 μg pyruvate kinase, 30 μmoles $(NH_4)_2SO_4$. The mixture was incubated for 30 min at 30° C. Binding capacity (×—×) was determined by measuring the retention on the filter of ^{3}H labelled ribosomal DNA[4]. The binding assay incubation mixture (0·3 ml.) contained 0·5 μg of rDNA, 0·1 ml. of the fraction to be assayed, 10^{-2} M Tris, 10^{-2} M $MgCl_2$, 10^{-2} KCl. The mixture was incubated for 10 min at 30° C and the reaction was stopped by dilution with 10^{-2} M Tris–10^{-2} M $MgCl_2$–10^{-2} M KCl (binding buffer). The content of the tube was filtered through 'Millipore' filters and the filters subsequently washed with binding buffer. *A*, DEAE-cellulose profile of enzymes extracted from ovaries; *B*, DEAE-cellulose profile of enzymes extracted from purified nucleoli.

of cistrons coding for the 18S and 28S ribosomal RNA and a spacer region of high G+C content.

Ribosomal DNA is a very efficient template when challenged with core RNA polymerase or core plus sigma from *E. coli*. Moreover, the bacterial core polymerase can copy this template asymmetrically[5]. The availability of rDNA prompted us to attempt the isolation of RNA polymerase from this organism.

RNA polymerase was isolated from ovaries as described in Fig. 2. Fig. 1*A* shows that two peaks of RNA polymerase activity can be eluted respectively with 0·15 M (peak I) and with 0·3 M KCl (peak II). The two peaks were also assayed for their capacity for retaining ^{3}H-labelled rDNA on 'Millipore' filters[6]; the distribution of rDNA capacity coincides with the polymerizing activity.

It has recently been reported that α-amanitin[7–10], a toxin from *Amanita phalloides*, is a potent inhibitor of the calf thymus RNA polymerase activity eluting at high ionic strength. Table 1 shows that α-amanitin completely inhibits the oocytes RNA polymerase peak II and is completely inactive against the activity eluting at 0·15 M KCl.

Table 1. EFFECT OF α-AMANITIN ON *Xenopus laevis* RNA POLYMERASES

Enzyme source	Peak	α-Amanitin	c.p.m.
Total ovary	I	—	285
		+	290
	II	—	766
		+	10
Purified nucleoli	I	—	344
		+	350

The incubation mixture and the incubation conditions were as described under Fig. 2. When indicated, the samples contained 10 μg/ml. of α-amanitin.

Roeder and Rutter[11] and Jacob *et al.*[10] reported that one of the activities common to all animal systems so far analysed is preferentially localized in the nucleolus. We now show that for *Xenopus*, the activity eluting with peak I is localized in the nucleolus and only peak I is capable of preferentially binding rDNA.

Young *Xenopus* oocytes are a good source of clean nucleoli because each cell contains about 800–1,000 extrachromosomal copies of this organelle which can therefore be isolated with little nucleoplasm contamination. Nucleoli were isolated from ovaries manually dissected from young tadpoles[12]; RNA polymerase was extracted as described above. Fig. 1*B* shows that the only RNA polymerase activity which can be extracted from nucleoli is the one eluting from DEAE-cellulose at low ionic strength (peak I). This activity was completely α-amanitin-insensitive (Table 1).

The nucleolar localization of activity I suggests[10,11] that this polymerase is involved in ribosomal RNA synthesis; because of the availability of pure rDNA we were able to confirm this hypothesis.

We found that *Xenopus* polymerases, like bacterial polymerases, retain DNA on 'Millipore' filters. Activity I and activity II were challenged with different kinds of DNA: ribosomal DNA (68 per cent G+C)[5]; *Xenopus* bulk DNA (42 per cent G+C)[13] free of ribosomal cistrons. The molecular weight of these DNAs was about 6×10^6.

Fig. 2 shows that the first peak eluted retains 90 per cent of rDNA but only 20 per cent of *Xenopus* bulk DNA free of ribosomal cistrons. The second peak can retain only 20 per cent of the DNAs tested. When the fraction of ribosomal DNA not retained by peak II was challenged with peak I, 90 per cent of the input was again retained. By contrast, no further retention was obtained when the same experiment was performed using peak II in the second assay. These results demonstrate that in purified ribosomal DNA there are sites that are recognized only by peak I and suggest that the nucleolar RNA polymerase is involved in rRNA synthesis *in vivo*.

Table 2. EFFECT OF α-AMANITIN ON STAGE 4 ENDOGENOUS AND σ STIMULATED RNA SYNTHESIS

σ Factor	α-Amanitin (μg/cell)	c.p.m. × 50 oocytes
	—	7,980
—	5	8,123
	+10	8,000
	20	8,029
	—	27,600
	5	15,427
+	+10	16,061
	20	15,743

Stage 4 oocytes were injected as previously described[10] and incubated for 8 h after injection. The oocytes were then collected and homogenized in 0·1 M acetate (*p*H 5·2). The homogenate was TCA precipitated, filtered on 'Millipore' and counted.

If the nucleolar RNA polymerase is responsible only for ribosomal RNA synthesis, the latter should be insensitive to α-amanitin *in vivo*. We tested this prediction by

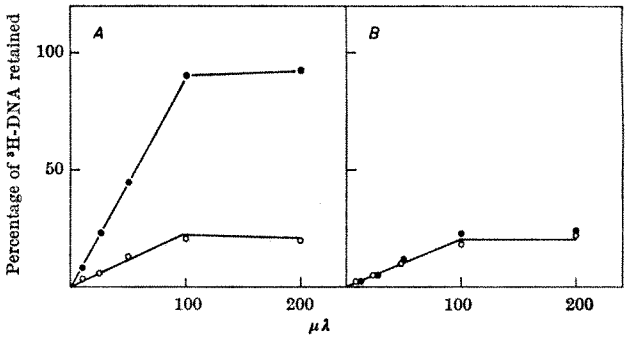

Fig. 2. Retention on 'Millipore' filters of *Xenopus* ribosomal DNA and *Xenopus* bulk DNA free of ribosomal cistrons by peak I and peak II. The incubation mixture (0·4 ml.) contained 0·5 μg of ^{3}H-DNA, increasing amounts of enzyme, 10^{-2} M Tris, 10^{-2} M KCl and 10^{-3} $MgCl_2$. The ribosomal cistrons were purified from *Xenopus* erythrocytes DNA. The purified cistrons banded as a homogeneous peak at a density of 1·724 g cm^{-3} and when hybridized with purified *Xenopus* ribosomal RNA showed a saturation plateau of 23 per cent[17]. The *Xenopus* bulk DNA was free of ribosomal cistrons as detected by hybridization with high specific activity *Xenopus* ribosomal RNA. ●, Retention of rDNA; ○, retention of *Xenopus* bulk DNA. *A*, Retention of ^{3}H-DNA by peak I (tube 31); *B*, retention of ^{3}H-DNA by peak II (tube 42).

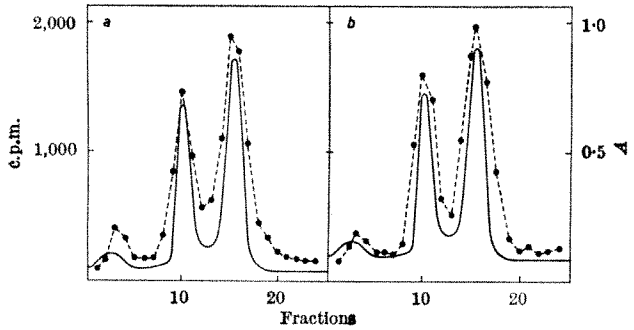

Fig. 3. Sucrose density analysis of RNA synthesized by stage 4 oocytes in the absence and presence of α-amanitin. Stage 4 oocytes were injected as described previously[19]; after injection the oocytes were incubated for 8 h and the RNA was extracted according to the procedure of Brown and Littna[18]. The RNA was precipitated with alcohol, dialysed against 0·1 M acetate (*p*H 5·0) and displayed on 15–30 per cent sucrose gradient. The gradient was centrifuged for 18 h at 22·5 r.p.m. in an 'SW 25·1' Spinco rotor. The gradients were collected with a continuous recording apparatus; the RNA was precipitated with TCA and counted. *a*, Control; *b*, α-amanitin was injected to reach a concentration of 10 μg/ml. in the oocyte.

micro-injecting α-amanitin into *Xenopus* stage 4 oocytes and early cleavage embryos. Stage 4 oocytes synthesize predominantly (more than 97 per cent) ribosomal RNA[14]. On the other hand, cells from early cleavage embryos do not synthesize any ribosomal RNA[15]. Table 2 shows that α-amanitin does not inhibit incorporation of ^{3}H-uridine into TCA precipitable material when injected into stage 4 oocytes. When the RNA synthesized in the presence of α-amanitin is extracted and analysed on a sucrose density gradient, the classical profile of ribosomal RNA is observed (Fig. 3). The possibility that α-amanitin is inactivated when injected into stage 4 oocytes is ruled out by the fact that the σ stimulated RNA synthesis in this cell is partially sensitive to α-amanitin, as previously reported[19]. Table 3 shows that α-amanitin completely inhibits RNA synthesis in early cleavage embryos, suggesting that peak II polymerase operates in those cells.

Table 3. EFFECT OF α-AMANITIN ON EMBRYONIC ENDOGENOUS AND σ STIMULATED RNA SYNTHESIS

Factor	α-Amanitin	c.p.m. ×50 eggs
−	−	6,725
	+	44
+	−	13,941
	+	7,844

Early cleavage embryos were injected as described[19] and then allowed to develop until early blastula. The cells were then collected and homogenized in 0·1 M acetate (*p*H 5·2). The homogenate was precipitated with TCA, filtered on 'Millipore' and counted. Where indicated α-amanitin was injected to reach a concentration of 10 μg/ml. in the egg.

We have tested two other inhibitors of RNA synthesis: 4-benzylidensiazo-4-deoxyrifamycin S (BDS) and methylbenzilidenaminopiperazine[16]. BDS is active on *E. coli* RNA polymerase and an enzyme extracted from a rifampicin-resistant mutant is relatively resistant. Methylbenzilidenaminopiperazine, on the contrary, is completely inactive against the bacterial enzyme. Both compounds inhibit RNA synthesis in stage 4 oocytes as well as in early cleavage embryos.

Because in stage 4 oocytes RNA synthesis is completely insensitive to α-amanitin, only the α-amanitin insensitive activity, that is, activity I, might be present in these cells. Our RNA polymerase is always prepared from oocytes of different stages and therefore the fact that we found two activities does not prove that this situation also refers to stage 4 oocytes. But by microinjecting *E. coli* σ factor into stage 4 oocytes, we found that 50 per cent of the RNA synthesis occurring under σ direction is α-amanitin-sensitive (Table 2). Because the bacterial σ probably functions by interacting with a cellular core enzyme like component, it seems likely that in stage 4 oocytes, besides the nucleolar polymerase (activity I), activity II is also present. Presumably the RNA synthesized by polymerase II under bacterial σ stimulation in stage 4 oocytes is non-ribosomal; it does indeed seem polydispersed when analysed by sucrose density gradient.

An opposite situation occurs in early cleavage embryos where all the RNA synthesis is α-amanitin-sensitive. When σ factor is injected into fertilized eggs, which are then allowed to develop until early blastula, a stimulation of 1·5–2-fold of incorporation of ^{3}H-uridine into TCA precipitable material is observed (Table 3). In this situation α-amanitin can no longer inhibit RNA synthesis completely; we therefore conclude that nucleolar RNA polymerase is present in these cells.

In stage 4 oocytes, as well as in early cleavage embryos, both polymerases I and II are present even if only one of them is producing measurable amounts of RNA. That the injection of *E. coli* σ factor stimulates both polymerases suggests that the endogenous initiation factor(s) could be limiting.

We thank Professors Fiume, Lancini, Silvestri and Wieland for the gift of inhibitors of RNA synthesis and B. Esposito, A. Lamberti and G. Locorotondo for technical help.

Synthesis of Serum Albumin, Prealbumin, α-Foetoprotein, α_1-Antitrypsin and Transferrin by the Human Yolk Sac

BOTH in the chick embryo and in the rat foetus, the yolk sac is an important, biologically active membrane throughout almost all of antenatal development. In the chick, the yolk sac envelops the great mass of yolk present in the egg and absorbs yolk material for embryo nutrition. The yolk sac in the rat forms one of the foetal membranes that encompass and protect the foetus, and during the last quarter of gestation it lies in direct apposition to the maternal endometrium. In both these species, the yolk sac synthesizes serum proteins[1,2]: in both, a serum iron-binding globulin and a serum α-globulin specific for the embryo or foetus are produced. The yolk sac of the chick also synthesizes serum albumin[2], a feat apparently not matched by the rat yolk sac[1]. The yolk sac of the human embryo, on the other hand, is a relatively small vesicle at the height of its development, and it soon degenerates to become atretic by the end of the

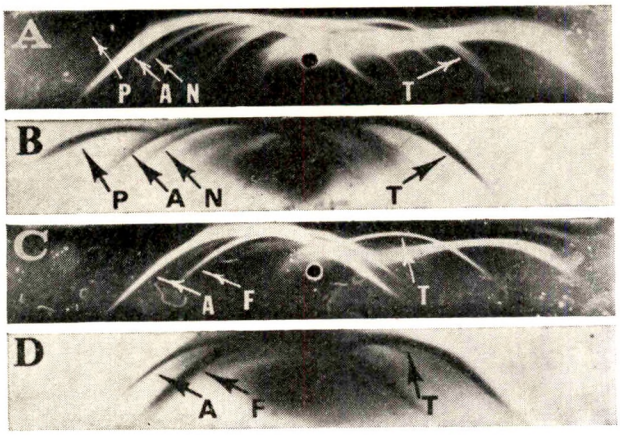

Fig. 1. Immunoelectrophoresis (*A*) and autoradiograph (*B*) of yolk sac culture fluid, embryo C9–68 of 5·5 weeks' gestation, with added adult serum and developed with rabbit antiserum against adult serum proteins. Immunoelectrophoresis (*C*) and autoradiograph (*D*) of yolk sac culture fluid of embryo C9–68 with added foetal serum and developed with rabbit antiserum against foetal serum proteins. Arrows P, A, N, F and T indicate prealbumin, albumin, α_1-antitrypsin, α-foetoprotein and transferrin, respectively.

first trimester of gestation[3]. The observation that the chick and rat yolk sacs can synthesize serum proteins prompted the present investigation into the possibility that the human yolk sac, too, might do so during its relatively brief existence as a well developed structure.

Table 1. PRESENCE OF RADIOACTIVE SERUM PROTEINS IN YOLK SAC CULTURES AS DETERMINED BY RADIO-IMMUNOELECTROPHORESIS

Conceptus	Gestational age (weeks)	Prealbumin	Albumin	α-Foetoprotein	α_1-Antitrypsin	Transferrin
C5–68	5·5	++++*	++	++++	++	++++
C9–68	5·5	++++	++	++++	++	++++
C11–68	8·5	+	++	+++	+	++
C7–68	11·5	0	+	+	0	+

* 0 = not detected; + to ++++ = increasing degrees of intensity of precipitation line on autoradiograph.

Through the cooperation of Dr Valdemar Madsen of the Amts Sygehuset in Gentofte, Denmark, yolk sacs were obtained from four human embryos which ranged from 5·5 to 11·5 weeks of gestation (Table 1). In the three younger embryos, each yolk sac was vesicular and had an excellent blood supply; the yolk sac of the 11·5 week embryo was solid and atretic. The yolk sacs were minced with scissors and cultured in roller tubes for 2–4 days at 37° C with 2 ml. of Eagle's basal medium containing Hanks's solution, 5 per cent horse serum and 2–4 μCi of L-^{14}C-leucine (specific activity 210 μCi/mmole). The cultures were dialysed against water for 3 days, lyophilized and then reconstituted to approximately 0·1 ml. with 0·1 M borate buffer of *p*H 8·6. Aliquots of human adult and foetal serum were added to aliquots of the concentrated culture fluids, and immunoelectrophoresis of the mixtures was performed in agar at *p*H 8·6 in 0·1 M borate buffer. The slides were developed for 3–7 days with rabbit antisera prepared against human adult or foetal serum proteins and rabbit antisera specific for either human serum albumin, α-foetoprotein, α_1-antitrypsin or transferrin[4]. The slides were then washed in 0·1 M NaCl for 2–3 days, dried, and inverted on 'RS Pan' film (Eastman Kodak, Rochester, New York) for 4–12 weeks for autoradiography. As controls, normal foetal and adult human sera were incubated with sterile culture medium containing radioactive leucine, and the mixtures were then studied in the same manner as the yolk sac cultures.

Relatively large amounts of radioactive prealbumin, albumin, α-foetoprotein, α_1-antitrypsin and transferrin were found in the yolk sac cultures of the embryos of 5·5 weeks' gestation (Fig. 1), and somewhat smaller amounts were present in the yolk sac culture of the 8·5 weeks' embryo (Table 1). No radioactive prealbumin or α_1-antitrypsin and only small amounts of radioactive albumin, α-foetoprotein and transferrin were found in the yolk sac culture of the 11·5 week embryo (Table 1). The radioactivity associated with the serum proteins in these cultures was not attributable to simple binding of radioactive leucine, for unlabelled foetal and adult serum proteins incubated with labelled leucine and culture medium in the absence of yolk sac did not become radioactive.

The nature of the radioactivity associated with serum albumin in the yolk sac culture was further investigated. Aliquots of concentrated yolk sac culture fluid of embryo C5–68 were mixed with 50 μg of purified human albumin in 1 ml. of 0·1 M NaCl, and the albumin was then precipitated with specific rabbit antiserum. The specific precipitates were washed three times with 0·1 M NaCl, resuspended in distilled water, adjusted to *p*H 8·0 with 0·1 M NaOH, heated to 100° C for 1 h and hydrolysed in the *p*H-stat[5] at *p*H 8·0 with α-chymotrypsin. The hydrolysates were concentrated by lyophilization, and subjected to high voltage electrophoresis on Whatman No. 1 filter paper. The papers were then dried and placed on 'RS Pan' film for 8 weeks: the autoradiographs revealed five radioactive bands (Fig. 2). Purified human albumin was also heat-denatured and hydrolysed with α-chymotrypsin; when the resulting peptides were separated on filter paper by high voltage electrophoresis and the peptide bands were developed with ninhydrin, five of the bands corresponded in relative position to the five radio-labelled bands (Fig. 2). As can be seen, the purified albumin hydrolysate contained peptides which did not have radioactive counterparts, though this was to be expected because leucine was the only labelled amino-acid in the yolk sac culture medium. The data indicate that labelled amino-acid was incorporated into serum albumin, and therefore that serum albumin was synthesized by the yolk sac.

At approximately 3 weeks of gestation, the human yolk sac is a pouch still broadly attached to the midgut; the liver at this stage is a thickened diverticulum of the gut just rostral to the yolk sac attachment[3]. By 4 weeks of gestation, the yolk sac is a well defined vesicle; and the liver is represented by hepatic buds and ducts[3] synthesizing prealbumin, albumin, α-foetoprotein, α_1-antitrypsin and transferrin in addition to many other serum proteins[4]. The youngest embryo in which the yolk sac was studied in the present report was 5·5 weeks in gestation: the amount of radioactivity incorporated into prealbumin, α-foetoprotein, α_1-antitrypsin and transferrin by the yolk sac at this stage as judged from the intensity of film blackening on autoradiography seemed to be equal to or greater than that incorporated *in vitro* by equivalent quantities of liver from the same embryo[4], although later in gestation the amounts were much less

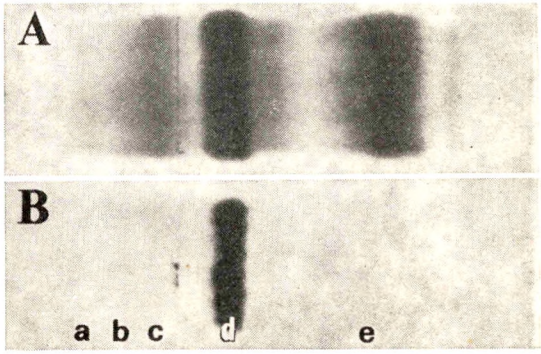

Fig. 2. High voltage electrophoresis (*A*) of peptides obtained from purified albumin by α-chymotryptic hydrolysis; pattern developed with ninhydrin. Autoradiograph (*B*) of high voltage electrophoresis of peptides obtained from the radioactive albumin specific precipitate from yolk sac culture fluid, embryo C5–68. Radioactive bands are marked *a* to *e*; bands *a*, *b* and *c* were very faint and difficult to reproduce photographically.

than in the liver cultures[4]. In none of the yolk sac cultures was as much radioactivity incorporated into serum albumin as in equivalent liver cultures.

This investigation was supported by a grant from the US Public Health Service.

Transmission of Mouse Neuroblastoma by a Cell-free Extract

A MOUSE tumour line, C1300, has been in serial transplantation since 1940 at the Jackson Laboratory, Bar Harbor, Maine. This tumour arose spontaneously from the region of the spinal cord in the body cavity of an albino mouse and was diagnosed tentatively as neuroblastoma; but until recently this could not be confirmed. Klebe *et al.* showed that C1300 tumour cells *in vitro* differentiate into neurone-like structures[1]. Similar results have been reported by others[2,3]. One of the identifying characteristics of cells derived from the sympathetic nervous system is the presence of the enzyme tyrosine hydroxylase. This communication reports the presence of tyrosine hydroxylase in the C1300 tumour, confirming the diagnosis of neuroblastoma. We also report that cell-free extract (CFE) of neuroblastoma tumour induces a similar neoplasm in the dermis, mesentery, spinal cord and sympathetic chain of mice after subcutaneous injections.

Male A/J mice inoculated with C1300 tumour tissue were obtained from the Jackson Laboratory. We are maintaining this neural tumour by serial transplantation in our laboratory. CFE was prepared as follows. Two weeks after transplantation the tissue-induced tumours were removed, minced or passed through a tissue press, and thoroughly homogenized in 0·25 M sucrose–isotonic–saline solution using a Potter–Elvehjem homogenizer with a 'Teflon' pestle. A 10 per cent homogenate was prepared and centrifuged at 3,000*g* for 10 min. The supernatant was examined under an inverted light microscope, found to be completely free of whole cells, and used as CFE. Unlike the light microscope, the inverted microscope allows one to scan the entire contents of CFE for the presence of whole cells. It is therefore unlikely that the presence of whole cells escaped our observation and, even if a few did, they would not have induced palpable tumours within the period of our observation (20 to 40 days). In our experience, subcutaneous injections of 5×10^5 cells induce palpable tumours between 15 and 20 days. In addition, the homogenate was centrifuged at 10,000*g* for 10 min and filtered through a 'Millipore' filter paper (pore size 0·45 μm). This filtrate (0·8 ml.) was used as CFE in nine series of experiments involving ten to thirteen animals per series. All procedures for the preparation of CFE were carried out at 4° C. CFE (0·4 ml.) was injected subcutaneously into the right axillary region of each mouse (4 to 8 weeks of age). Control mice received an equivalent volume of sucrose–saline solution. Tyrosine hydroxylase activity was assayed in 0·25 M sucrose homogenates of CFE and tissue-transplanted tumours using L-^{14}C-tyrosine according to the method of Nagatsu[4]. Tyrosinase activity was measured using the method of Pomerantz[5]. Protein content of the homogenate was determined by the method of Lowry *et al.*[6]. Both CFE and tissue-induced tumours were then examined for viruses by electron microscopy.

CFE-induced tumours were compared with those of tissue-transplanted neoplasms on the following criteria: (*a*) tumour induction time after transplantation, (*b*) histology, (*c*) serial transplantability of CFE, (*d*) cell differentiation *in vitro*, and (*e*) tyrosine hydroxylase and tyrosinase activities.

CFE-injected mice showed palpable tumours in the dermis in 18 to 40 days after injection; but the mice which received tissue transplants showed tumours of similar size between 8 and 10 days after transplantation. Table 1 shows the incidence of tumours in tissue and CFE-injected mice. Most CFE-injected mice developed tumours under the skin and on the same side as the injection; but four tumours appeared on the opposite side from the initial injection. In addition, three tumours developed in the superior region of the neck and three within the intraperitoneal cavity. After 30 days of subcutaneous injection, animals with intraperitoneal

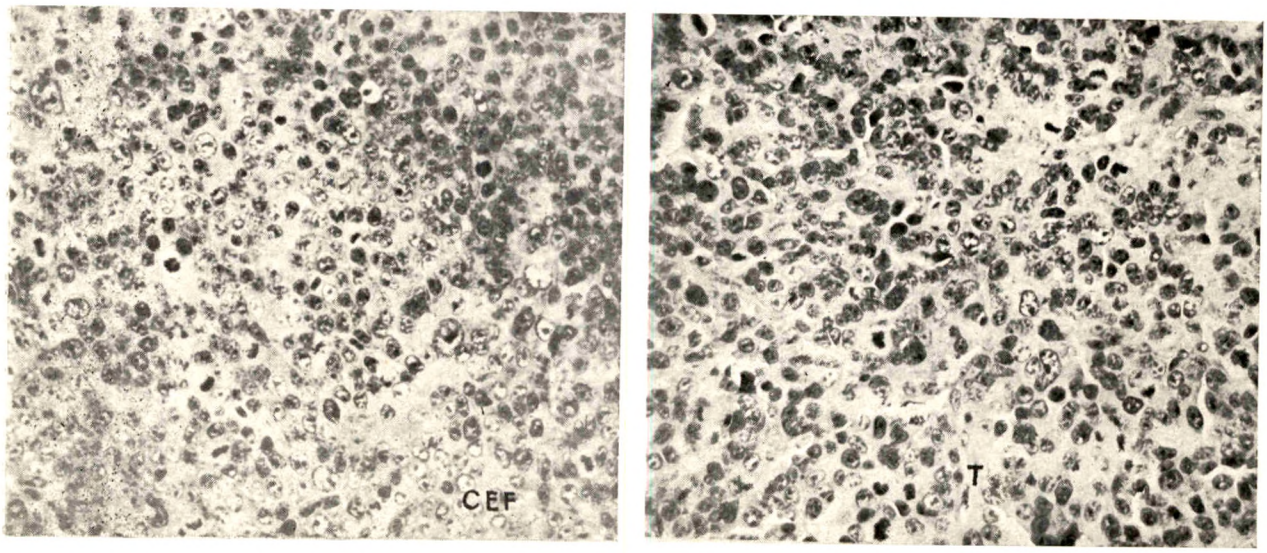

Fig. 1. Sections of tissue (T) and cell-free extract (CFE) induced tumours stained with haematoxylin–eosin. Note round cells, frequent mitoses and occasional giant cells in both tumours (×132).

tumours had distended abdomens filled with reddish fluid. The entire mesentery beginning from stomach down to the large bowel had a sheet of nodular tumour mass. The mesentery covering the ventral surface of the spleen also had a tumour mass extending the entire length of the spleen. Other areas involved included the spinal cord and sympathetic chain. To establish whether or not mice with tissue-induced tumours also had lesions within the peritoneal cavity, five mice were killed and examined 30 days after transplantation. The mesentery, spinal cord and sympathetic chains were not involved. One mouse showed a tumour in the liver and right kidney, whereas another showed a tumour in the left adrenal. This may be due to metastasis of the original tumour or induction of a new tumour by virus.

Table 1. INDUCTION OF NEUROBLASTOMA TUMOURS BY CELL-FREE EXTRACT (CFE)

No. of animals	Treatment	Incidence of tumour (per cent)
35	Piece of tissue-induced tumour	100
59	CFE of tissue-induced tumour	75
15	Piece of CFE-induced tumour	100
20	Sucrose–saline	0

A 10 per cent homogenate of neuroblastoma tumour was centrifuged at 3,000*g* for 10 min. The supernatant was used as CFE. Each mouse received 0·4 ml. of CFE subcutaneously.

CFE obtained after filtration through a 'Millipore' filter produced neuroblastoma tumour (40 to 70 per cent) in five series, whereas in the other four series no tumour was detected. This kind of variable result was expected, because most of the viruses are enclosed within the endoplasmic membranes (Fig. 3); centrifugation at high speed and filtration through a 'Millipore' filter might therefore reduce the viral contents of the filtrate. The amount of virus in the CFE would thus vary markedly from one preparation to another.

Grossly, both CFE and tissue-induced tumours appeared as soft pink masses with nodular growths. A histological study of tumour tissues (three animals from each group) was carried out after fixation in 10 per cent neutral buffered formalin. Paraffin sections of these tumours stained with haematoxylin–eosin showed that both tissue and CFE-induced tumours had similar cellular features (Fig. 1). The cells were round or polyhedral and not present in any recognizable pattern; giant cells with oval nuclei were occasionally seen. Mitosis appeared more frequently in CFE-induced than in tissue-transplanted tumours.

The CFE-induced tumours were transplantable with the same efficiency as the tissue-transplanted tumours; and CFE of CFE-induced tumours also produced similar neoplasms, suggesting that causative agents are not lost during the experimental procedure.

To compare their cellular behaviour *in vitro*, cells from CFE-induced tumours and tissue-transplanted tumours were cultured according to the method described by Klebe *et al.*[1]. Briefly, cells were grown in F12 medium containing 10 per cent agammaglobulin newborn calf serum and maintained at 36° C in a humidified atmosphere of 5 per cent CO_2 and air. After 12 days in culture, cells in the falcon plastic flask were fixed with 3 per cent glutaraldehyde for 10 min and stained with 0·1 per cent cresyl violet for 10 min. Fig. 2 shows the cells of CFE and tissue-induced tumours *in vitro*. The cellular features were identical in both tumours. In a given population undifferentiated round cells, unipolar and bipolar neuroblasts, and neurones with long dendritic processes are seen.

Tyrosine hydroxylase and tyrosinase activities were measured in 14 day old tissue-transplanted tumours and 35 day old CFE-induced tumours. Both groups of tumours were of similar size at this time. As seen in Table 2, the C1300 tumour had a high tyrosine hydroxylase activity indicating its neural origin. The presence of similar amounts of tyrosine hydroxylase in both the tissue-transplanted and CFE-induced tumours shows that

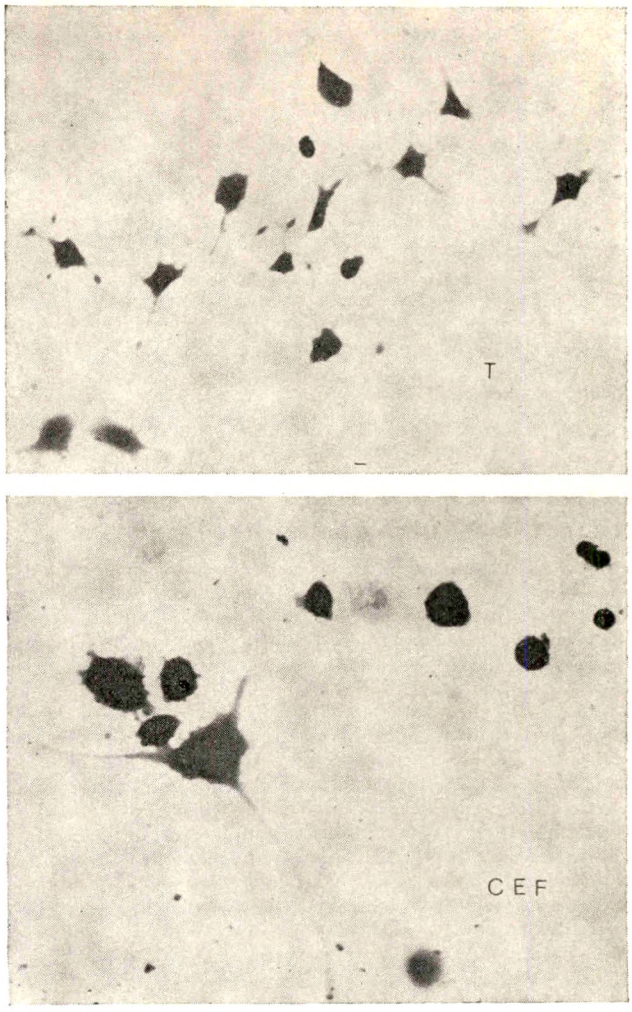

Fig. 2. Cellular morphology *in vitro*. Cells from tissue (T) and CFE-induced tumours stained with cresyl violet. Note undifferentiated round cells, unipolar and bipolar neuroblasts and neurones with dendritic processes in both tumours (×40).

the same tumour is transmitted by the CFE. Because the CFE could be converting dermal melanoblasts (derived from neural crest) into neuroblastoma cells, tyrosinase was also measured but was not detectable in any of these tumours (Table 2).

Table 2. ANALYSIS OF TYROSINE HYDROXYLASE AND TYROSINASE IN C1300 TUMOURS

Tumours	No. of animals	Tyrosine hydroxylase (nmoles of tyrosine/h/g protein)	Tyrosinase
Tissue transplanted tumour	4	30·5±0·9*	0
CFE-induced tumour	4	35·6±2·6*	0

* Standard error of the mean.

Fragments of transplanted and CFE-induced tumour tissues were fixed in 4 per cent glutaraldehyde in S-collidine buffer (*p*H 7·45), post-fixed in 1 per cent OSO_4 plus S-collidine buffer, embedded in 'Epon 812', and stained with lead citrate for an electron microscopic observation. The virus-like particles were present in both CFE and tissue-induced tumours. Fig. 3 shows the presence of several virus-like particles in the cytoplasm. Some of the viruses seem to bud off from endoplasmic reticuli, and several mature viruses are enclosed within endoplasmic reticuli. Neuroblastoma tumours also contained a few electron-dense vesicles which may represent storage sites of catecholamines (not seen in picture).

Transmission of tumours by CFE has been reported for other neoplasms[7–10]; but this is a first demonstration of the induction of a neuroblastoma tumour by CFE.

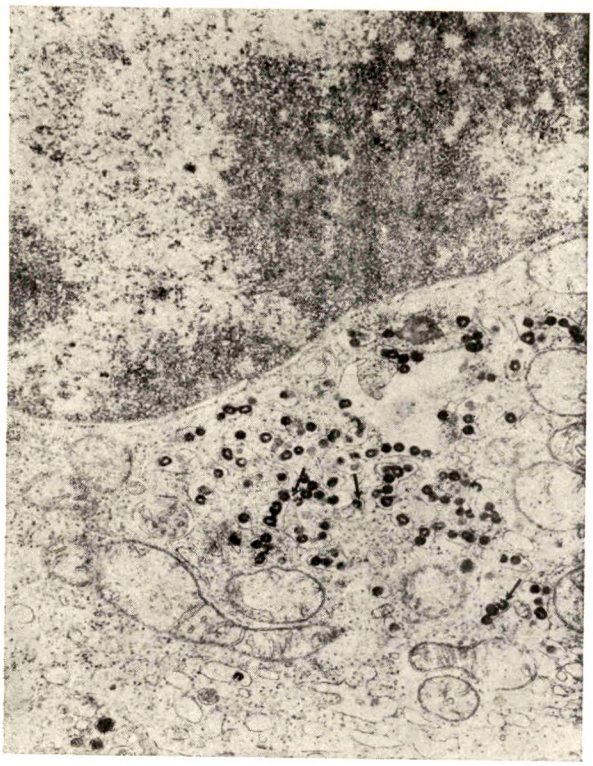

Fig. 3. Electron micrograph of tissue-induced tumour. Note the abundance of virus-like particles in the cytoplasm. Viruses appear to bud off from endoplasmic reticuli (indicated by arrows). Mature viruses are enclosed within the endoplasmic membranes (×17,364).

The presence of virus-like particles in the neuroblastoma tumour suggests a viral origin for this tumour. The most sensitive target areas, which are transformed to neuroblastomas, are the dermis, mesentery, spinal cord region and sympathetic nerve cells. It is apparent that certain nerve cells are being transformed; but whether other cell types can also be transformed remains to be ascertained. Studies are now in progress to elucidate the mechanism of induction of mouse neuroblastoma by CFE.

We thank Mrs Marianne Gashler for technical help. This work was supported in part by a grant from the Milheim Foundation for Cancer Research, US AEC, and the American Cancer Society.

Effect of L-Dopa on the Sleep of Man

NORMAL sleep in man consists of two alternating phases which may be distinguished by electroencephalographic (EEG), electromyographic, electro-occulographic, autonomic and psychologic criteria[1-3]. The initial period of nocturnal sleep is characterized by EEG spindles and slow waves, partial preservation of muscle tone, and regularity of pulse and respiratory rates. After about 90 min, this non-rapid eye movement (NREM) phase of sleep gives way to a period of irregular, low voltage electrocortical activity, bursts of rapid eye movements, profound hypotonia of certain muscles, rapid alterations in cardiorespiratory function and in human dreaming. Ordinarily, rapid eye movement (REM) sleep alternates with NREM sleep four or five times each night, and occupies 20 per cent to 25 per cent of total sleep time.

Several lines of inquiry suggest that brain monoamines play an important role in the regulation of both REM and NREM sleep[4]. Lesions which selectively destroy certain noradrenaline or serotonin-containing neurones, or drugs which influence one or more aspects of the metabolism or disposition of these monoamines, profoundly affect sleep patterns[5-8]. Such observations in laboratory animals have led to the suggestion that REM sleep may depend on catecholamine-containing neuronal systems, whereas serotonin-containing systems may be involved in the mechanism of NREM sleep[4]. This study was carried out to determine the effect of L-dopa, the immediate precursor of dopamine and noradrenaline, on human sleep. Results in seven patients indicated that the administration of L-dopa, at doses which modify extrapyramidal function, is attended by a significant reduction in REM sleep time.

Five women and two men (three with Parkinson's disease, two with Huntington's chorea, one with dystonia musculorum deformans and one with essential hypertension) were studied by continuous all-night recordings of EEG, horizontal electro-occulogram and submental electromyogram (Table 1). Each patient slept in his usual hospital room and was left undisturbed until awakened after 8 h of possible sleep. Other medication was discontinued before the study began except for patient 6, who remained on a constant amount of benztropine mesylate (Cogentin). Throughout the investigation a constant number of identical capsules containing either placebo or active drug were administered seven times each day. Three patients (2, 5 and 6) received L-dopa in combination with (+, −)-α-methyl-dopa-hydrazine (MK 485, supplied by Merck Sharp and Dohme Co., West Point, Pa.), a peripheral decarboxylase inhibitor, which does not enter the central nervous system. By blocking the conversion of exogenous dopa to dopamine outside the central nervous system, peripheral decarboxylase inhibitors make dopa available for conversion within the brain parenchyma[9]. Sleep recordings were made during a week of placebo administration and during a subsequent period of L-dopa treatment. The first two nights of sleep study were used to adapt patients to the slightly unnatural sleeping conditions and no data from these nights were included in the results. The placebo baseline for each patient was five nights. In four patients data during drug administration were taken from the five nights of highest L-dopa dosage. Because L-dopa produced insomnia at the highest dosage in three other individuals (2, 6 and 7), however, data in those patients were taken from the five nights just preceding highest dosage. Sleep records were evaluated according to standardized criteria[10] by a scorer who was unaware of whether the patients were receiving placebo or drug.

L-Dopa led to a reduction ($P < 0{\cdot}01$) in the duration of REM sleep in all seven patients (Table 1). The decrease ranged from 4 per cent to 46 per cent of baseline. Moreover, the minutes from sleep onset to the first REM period (REM latency) increased from a mean of 47 min

Table 1. EFFECT OF L-DOPA ON REM LATENCY, REM SLEEP TIME AND NREM SLEEP TIME*

to 113 min ($P < 0.001$). There was no change in the duration of NREM sleep. Data for patient 2 are shown in Fig. 1. REM sleep time, although quite variable, decreased significantly when the patient received L-dopa. While the duration of NREM sleep also fluctuated considerably, there was no consistent change until the last four drug nights when NREM sleep fell precipitously in association with almost total insomnia. No further decrease in REM sleep occurred at this time. Discontinuation of L-dopa was associated with a marked rebound elevation in REM sleep. In patient 5 an increase in the duration of REM sleep persisted for ten nights following withdrawal of L-dopa. The effect of L-dopa withdrawal on the duration of REM sleep was not studied in the remaining five patients.

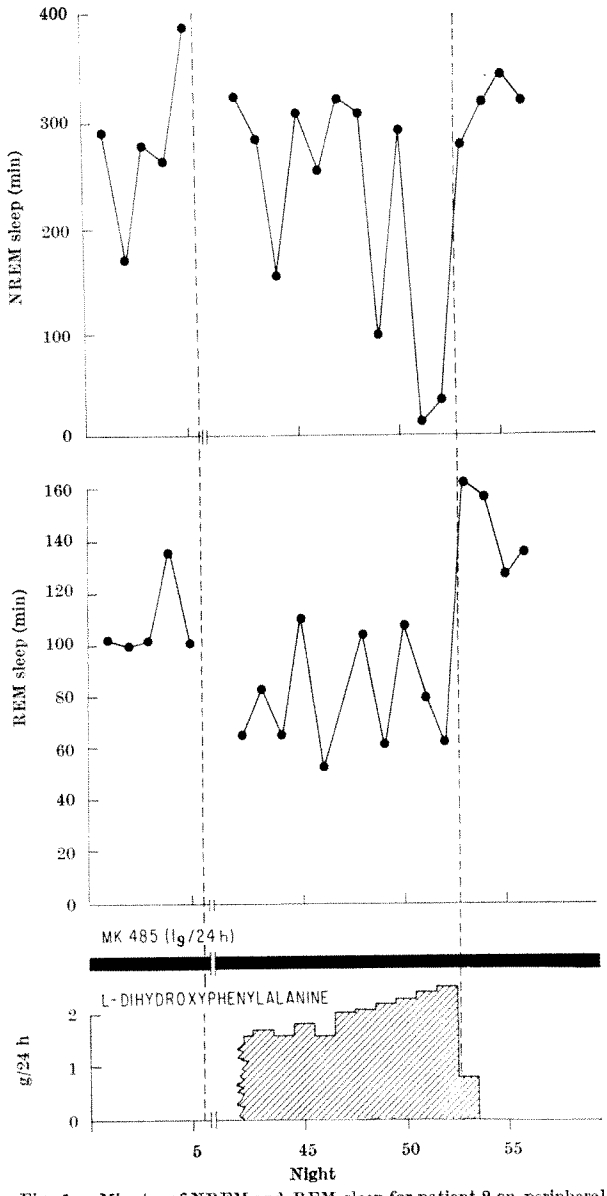

Fig. 1. Minutes of NREM and REM sleep for patient 2 on peripheral decarboxylase inhibitor (MK 485) plus L-dopa.

At submaximal L-dopa dosage several patients had apparent rebound elevations in REM sleep during the second half of the night. This effect was most marked in patient 3. While receiving 1,200 mg/day of L-dopa total REM time during the last 4 h of sleep averaged 98 min compared with 69 min during the placebo period. This observation suggests that the effect of L-dopa on REM sleep is quite transient. As a test of this possibility patients 3 and 6 were given L-dopa on a schedule which omitted any drug dosage during the 2 h preceding bedtime. In such conditions REM time did not differ appreciably from baseline levels. When the same daily dosage of L-dopa was distributed so that the last dose (500 mg of L-dopa) was given within 30 min of bedtime, REM sleep was reduced 45 per cent and 49 per cent below baseline.

The administration of L-dopa results in a substantial elevation of brain dopamine. Noradrenaline concentrations in brain are probably not increased by exogenous L-dopa, especially when given with a peripheral decarboxylase inhibitor[11]. Lumbar punctures were performed in standardized conditions[12] during the pre-drug period and the time of maximum L-dopa dosage. Assays were carried out by previously described methods[13]. The increased cerebrospinal fluid levels of homovanillic acid, the principal metabolite of dopamine, found in patients included in the present study (Table 2) suggest that central dopamine concentrations were elevated by L-dopa at a time when REM sleep was reduced.

Table 2. HOMOVANILLIC ACID LEVELS IN CEREBROSPINAL FLUID OF PATIENTS RECEIVING L-DOPA*

Patient	Drug dose (g/24 h) L-Dopa	Homovanillic acid Placebo	Homovanillic acid Treatment
1	4·0	≤4	383
2	2·5*	12	264
5	0·6*	5	40
6	2·2*	14	300
7	10·0	62	909

* L-Dopa plus 1·0 g MK 485.

We have previously observed increases in REM sleep when catecholamine synthesis was inhibited by α-methylphenylalanine or α-methyl-paratyrosine (R. J. W., T. N. C., D. J. Kupfer, J. S., F. S., and A. Sjoerdsma, unpublished). The finding that L-dopa decreases REM sleep lends further support to a relationship between catecholamines and the duration of REM sleep in humans. By contrast, studies using parachlorophenylalanine (PCPA), an inhibitor of serotonin synthesis, indicate that decreases in serotonin are associated with a reduction in REM sleep in man[14]. Administration of the serotonin precursor, 5-hydroxytryptophan, returns REM sleep to baseline in the presence of PCPA. Furthermore, 5-hydroxytryptophan has been found to increase REM sleep in normals[15,16]. Animal studies indicate that the cate-

cholamines promote REM sleep[1]; our data indicate that in man catecholamines tend to inhibit and serotonin tends to enhance REM sleep.

Synthesis of γ-Aminobutyric Acid in Fish Erythrocytes

WE have found evidence of high activity of the enzyme glutamate decarboxylase (GAD) outside the nervous system. This enzyme catalyses the formation of γ-aminobutyric acid (GABA), which is believed to be an inhibitory neurotransmitter[1]. Recently, however, a high concentration of GABA (11 mmoles/kg wet weight) was found in flounder (*Pleuronectes flesus* L.) erythrocytes, where GABA may participate in the maintenance of a steady cell volume during changes in plasma osmolality[2,3].

The formation of GABA from glutamate was demonstrated as follows. Erythrocytes were homogenized in isotonic saline and incubated for 1 h at 10° C with 0·6 μmole/ml. homogenate of DL-[5-^{14}C]glutamate (specific activity 3·7 mCi/mmole, New England Nuclear Corp.). Amino-acids were extracted with alcohol and separated by thin-layer chromatography[3]. Spots were visualized by autoradiography and by treatment with ninhydrin reagent. The main labelled ninhydrin-positive product could not be distinguished from GABA (Fig. 1, *a*5 and *b*5). Radioactivity was also found in three other substances, one of which (Fig. 1, *b*6) was tentatively identified as α-ketoglutarate. No metabolism of GABA was detected by incubating with 5-^{14}C-GABA in similar conditions.

GAD activity was measured at 25° C by a micro method[4] depending on the production of $^{14}CO_2$ from L-[1-^{14}C]-glutamate (California Biochemical Corp.). The incubation mixture contained (final concentration): 3·5 mM sodium L-glutamate (75,000 c.p.m.), 20 mM sodium phosphate buffer (*p*H 6·5), 1 mM dithiothreitol, 0·1 mM pyridoxal phosphate and 0·25 per cent of 'Triton X-100'. In these conditions the activity of rat brain was 4·70 ± 0·25

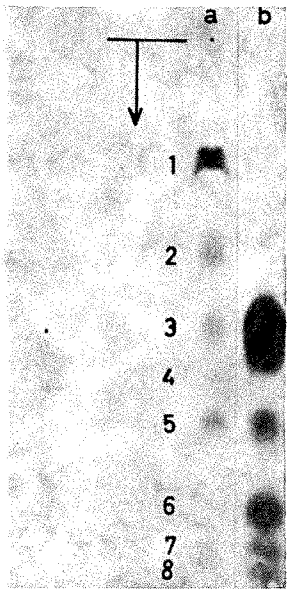

Fig. 1. *a*, Chromatogram of alcohol extract from flounder erythrocytes, showing the ninhydrin-positive spots (1–5); 3 = glutamate; 5 = GABA. *b*, Autoradiogram of the chromatogram *a*, showing the radioactive spots (3 and 5–8); 3 = glutamate; 5 = GABA; 6 = α-ketoglutarate.

μmoles/h/g wet weight (mean ± s.e., three experiments). In flounder, the following GAD activities (μmoles/h/g wet weight) were found: erythrocytes, 0·93 ± 0·08 (mean ± s.e., six animals); brain, 2·65 ± 0·27 (mean ± s.e., six animals). Other tissues contained low activities (liver, 0·06; kidney, 0·03—serum not detectable, one animal) some of which is accounted for by the presence of retained blood cells.

Like GAD of rat brain, the enzymes from flounder erythrocytes and brain were extractable with water, and were inhibited by high concentrations of Cl^- and by inactivation of pyridoxal phosphate. Thus, the erythrocyte enzyme was inhibited 77 per cent by 300 mM KCl and 69 per cent by 2 mM NaCN. The figures for the brain enzyme were 88 per cent and 72 per cent. K_m values measured at 25° C were for flounder erythrocytes 2·3 mM, for flounder brain 24 mM and for rat brain 12 mM (means of two experiments). It is interesting that flounder erythrocytes contain a low concentration of glutamate (less than 0·2 mmole/kg wet weight)[3].

GAD had been thought to occur solely in nervous tissue[1], but has recently been observed in mammalian kidney[5,6]. The kidney enzyme, however, differs from GAD of brain and of flounder erythrocytes for it is activated by Cl^- and probably does not require pyridoxal phosphate[5].

Natural α-radioactivity Concentrations in Bone and Liver from Various Animal Species

THE radiation dose received by man as a result of exposure to naturally occurring nuclear radiation has been investigated thoroughly in recent years, and critical summaries of the data are available[1-4]. The natural radiation dose received by other animal species has received less attention. The principal source of interspecies variation in the dose is likely to be the contribution from internally deposited alpha-emitting nuclides[5]. Mayneord[6] has referred to this "almost untouched field of research", and he and his co-workers[7,8] have tabulated total alpha-activities in bone ash from about a dozen different animal species. Although data on specific isotopes in certain species have been reported[9-16], there is to our knowledge no other comparative interspecies study. We report here the preliminary results of a similar but more extensive study. The data have been obtained using the total alpha-counting technique developed by Turner *et al.*[17] and used previously in this laboratory[18-21]. We have prepared our samples for counting by cleaning, steaming, drying and grinding (bones) or by freeze-drying and grinding (soft tissues).

In Table 1 we list our data for bone samples from various species. All samples were obtained from Southern Africa, and most were of femur bone. Activities are quoted in pCi/kg wet bone, and the mean concentration factor[22] from the wet bone to the dry bone (as counted) state was 1·3. It is important to note that the total alpha-activities have been corrected, where applicable, for polonium-210 fall-off and are expressed as activities at time of collection. They also include full equilibrium contributions from radon and other radium-226 daughters; such contributions will in general not be present in full in the *in vivo* state[3]. Several of the samples did show a component of the activity which decreased with time in accordance with the 138 day half-life of polonium-210, and this is interpreted as being due to "excess", unsupported, polonium-210 alpha-activity. This interpretation was checked in several cases by alpha-spectroscopy using a large area ion-chamber of the type designed by Hill[23]. In the last column of Table 1 the percentage of the total alpha-activity due to this excess polonium-210 is given.

In man, the greater part of the total alpha-radioactivity is found to reside in the bony skeleton[2,8]. This will not necessarily be so in other species, and we have measured samples from soft tissues as well as bone. In Table 2 we list data from the "livers" of various species; these show interesting features, although they are not to be considered as representative of soft tissues in general.

Table 1. ALPHA-RADIOACTIVITY IN BONE FROM VARIOUS SPECIES

Species	No. of samples	Total alpha-activity in pCi/kg wet bone	Percentage due to excess polonium-210
Cattle	3	6,600	34±17
Sheep	2	4,000	43± 7
Horse	1	1,900	79±25
Donkey	1	1,900	44±10
Buck	1	1,600	32± 8
Fish (sea)	10	1,200	—
Dog (domestic)	4	910	N.D.
Cormorant	1	800	79±14
Jackal	1	720	N.D.
Hyena	1	680	N.D.
Dog (wild)*	2	670	N.D.
Dove	1	580	N.D.
Leopard*	1	420	N.D.
Chicken	1	400	N.D.
Baboon	1	390	N.D.
Elephant*	3	380	N.D.
Zebra*	3	320	N.D.
Lion	1	290	N.D.
Cheetah	1	270	N.D.
Seal	4	240	N.D.
Man	7	240	N.D.
Pig	7	140	N.D.

Counting statistics give an error of less than 15 per cent on all of the total alpha-activity values. Asterisks denote "old" bone samples of uncertain date of death. N.D. denotes not detected within the limits of counting statistics, and implies that the percentage of the total alpha-activity due to excess polonium-210 is less than 15 per cent. The excess polonium-210 percentage was not calculated for fish bone since it was observed to be statistically different from zero in only one out of the ten samples measured.

Table 2. ALPHA-RADIOACTIVITY IN "LIVER" FROM VARIOUS SPECIES

Species	No. of samples	Total alpha-activity in pCi/kg wet liver	Percentage due to excess polonium-210	Liver-to-bone total alpha-activity ratio
Rock lobster	9	14,800	84± 6	38*
Fish (sea)	10	1,300	71±23	1·1
Seal	4	930	96± 2	3·9
Cattle	2	160	39±19	0·02
Buck	4	150	43±33	0·09
Dog (domestic)	4	83	N.D.	0·09
Pig	9	67	N.D.	0·48
Sheep	2	66	N.D.	0·02
Man	10	26	N.D.	0·11

The asterisk for rock lobster denotes a liver-to-shell and not a liver-to-bone activity ratio. Rock lobster shell was found to have a mean total alpha-activity of 390 pCi/kg.

The results of Mayneord's group[5,7,8] provide data which can be compared most easily with our own total alpha-activity values. Our data for human bones are seen to be at a level similar to that of the Cornish bone samples[5], that is, higher than average. Both our data and those of the Mayneord group give higher bone alpha-activities than are implied in the UNSCEAR report compilation of bone radioactivity due to individual alpha-emitting nuclides. This could reflect a difference in experimental technique, but is quite possibly a variation which reflects real differences between the alpha-activities in human bone from different localities[24]. For species other than man, our results also show general agreement with earlier bone data, although here, too, wide activity variations within a single species are to be emphasized.

As tentatively suggested by Mayneord[6], man is clearly close to the bottom of the radioactive species scale. The pig is the only other species investigated by us which has a comparably low alpha-activity content in both bone and liver. Our results confirm the low values of Nelson and Rust[12] for pig bones. At the other extreme, herbivore bones and the marine animal "livers" are more radioactive than the corresponding human organs by one or two orders of magnitude.

It seems that the concentrations of radium-226, radium-228 and excess polonium-210 must be much higher in herbivore bones than in man. In marine livers, on the other hand, it is excess polonium-210 alone which is largely responsible for the high activity levels. The source of the polonium-210 activity is not hard to find: herbivores eat grass[13,25], and the first link in the marine food chain is plankton[18,20].

Although food intake seems to be the main determinant of alpha-radioactivity content of a species, other factors must be important as well. The liver-bone alpha-activity ratios in Table 2 illustrate this point. This ratio is greater than one for the marine species measured, while for herbivores it is less than 0·1. The ratios for man and pig lie in between these two values. A specific metabolic mechanism on the part of the marine "livers", probably involving direct uptake of polonium-210, is indicated. Then consider the pig. The physiological similarity between man and pig is well known[26], and it is tempting to associate the low levels of alpha-activity in both man and pig with a physiological factor. On the other hand, this similarity in activity levels could result from the similarity in human and porcine eating habits[12]. The pig samples measured in our experiments were obtained from pigs used in a feeding experiment designed for agricultural purposes. We measured the alpha-activity of the food on which these pigs had been fed, and calculated an intake of about 1,920 pCi/day per pig. Alpha-activity values for human foodstuffs as reported in the literature[5,8,27] show that any reasonable daily average for the human dietary intake is an order of magnitude lower than this figure. It seems that food intake by itself cannot explain the concentrations of the alpha-emitters in biological tissues.

The natural radiation dose from nuclear radiations must differ widely between different species. A typical

compilation of the human natural radiation dose[3] results in a dose estimate of about 150 mrem/year to human bone. Of this about 30 per cent is the result of internally deposited alpha-emitters. For either herbivore bones or marine "livers" our data predict a total natural radiation dose in excess of 1,000 mrem/year, and 90 per cent or more of this is due to alpha-radiation.

Respiratory Mechanisms and the Metazoan Fossil Record

THE fossil record sheds little light on the problem of metazoan origins. Most of the major metazoan phyla appear in the fossil record in the Cambrian but no ancestral organisms have been found in the Precambrian, although suitable non-metamorphosed Precambrian rocks exist[1]. The oldest known metazoan fossils (latest Precambrian) are those from the Ediacara formation, Australia[2]. These fossils represent soft-bodied metazoans, some of which have been assigned to the coelenterates, some to the annelids, while others are of uncertain phyla[3]. Glaessner suggests[2] that the Ediacara animals may be significant as a stage in the evolution of small, soft-bodied animals to larger forms with the gradual acquisition of fossilizable exo-skeletons or shells.

Berkner and Marshall have proposed[4] that large scale production of oxygen by phytoplankton did not begin until there was enough oxygen in the atmosphere for the production of a protective layer of ozone, and when this had occurred (1 per cent of present level of oxygen) the metabolism of many organisms shifted from fermentation to respiration. Cloud has suggested[5] that this occurred between 1·2 and 0·6 billion years ago. Towe has proposed[6] that ancestral metazoans, operating at minimal oxygen levels, would not have possessed the oxygenases involved in collagen synthesis. With only a little collagen, these animals were soft, small and had little chance of being fossilized, but as the level of atmospheric oxygen increased near the beginning of the Cambrian, metazoans would have been released from this restriction, and the evolution of rigid structures was a selective advantage.

It does not seem necessary that ancestral metazoans were limited to conventional collagen as a primary connective material. If there had been evolutionary pressure toward a firmer body structure, it is likely that a connective material not requiring an oxygenase would have been evolved. Such a connective protein is illustrated by the collagen of *Ascaris*, which lives in an almost anaerobic environment and functions largely on glycolysis[7]. This collagen contains little hydroxyproline but large amounts of proline, and seems to lack hydroxylysine. Josse and Harrington have shown[8] that stabilization of collagen depends on its total pyrrolidine content and not on hydroxyproline alone.

We propose here that the limited oxygen of the atmosphere at the time of the evolution of early metazoans limited the absolute size attainable by a metazoan animal and thus obviated the need for a firm body. The earliest metazoans must have obtained their oxygen by diffusion. Calculations of the maximum possible sizes of diffusion animals indicate that, in modern oxygen conditions, animals with fairly high metabolic rates are limited in size to about 1 mm in thickness[7,9].

We have calculated thicknesses possible for such animals whose shape is that of a flat sheet in hypothetical primitive Earth atmosphere conditions.

The steady state equation describing such diffusion is

$$D\frac{d^2c}{dx^2} = Q = \frac{V\bar{K}c}{1+\bar{K}c} \qquad (1)$$

where c is the concentration of oxygen within the tissue sheet, x is the distance through the sheet measured from the surface, and D is the diffusion coefficient of oxygen within the tissue, Q is the rate of consumption of oxygen by the tissue, assuming an enzymic process following Michaelis–Menton kinetics where V is the maximum velocity of the consumption reaction and $\bar{K}$ is the reciprocal of the Michaelis constant (K_m).

Blum and Jenden have shown[10] that a good approximate solution to equation (1) may be obtained with a Taylor series expansion method. Applying the boundary conditions ($c=c_0$ at $x=0$ and $x=2b$, where c_0 is the concentration in the medium and $2b$ is the thickness of the tissue), the following solution is obtained[10,11]

$$c=(c_0+\bar{K}c^{*2})\left\{\cosh(\alpha^{\frac{1}{2}}x/1+\bar{K}c^*) - \left[\frac{\sinh(\alpha^{\frac{1}{2}}b/1+\bar{K}c^*)}{\cosh(\alpha^{\frac{1}{2}}b/1+\bar{K}c^*)}\right]\sinh(\alpha^{\frac{1}{2}}x/1+\bar{K}c^*)\right\} - \bar{K}c^{*2} \qquad (2)$$

where $\alpha = V\bar{K}/D$, and c^* is an "average" concentration, a constant different for each value of b and chosen to give a maximum b for each set of conditions[10].

We have determined the thickness attainable ($2b$) by a hypothetical diffusion animal for various values of c_0 by assigning an arbitrary value of c_{min} (the minimum oxygen concentration at the middle of the tissue) and solving equation (2) for $x=b$. c_{min} was chosen equal to a low concentration greater than zero ($0{\cdot}1\times Km$ for oxygen of yeast cytochrome oxidase). It was assumed that the Km of the primitive metazoan cytochrome oxidase was similar to that of modern organisms for such diverse systems as yeast and mammalian mitochondria have similar Km values[12].

The results of calculations of the maximum tissue thickness attainable by model diffusion organisms operating at various rates of oxygen consumption as a function

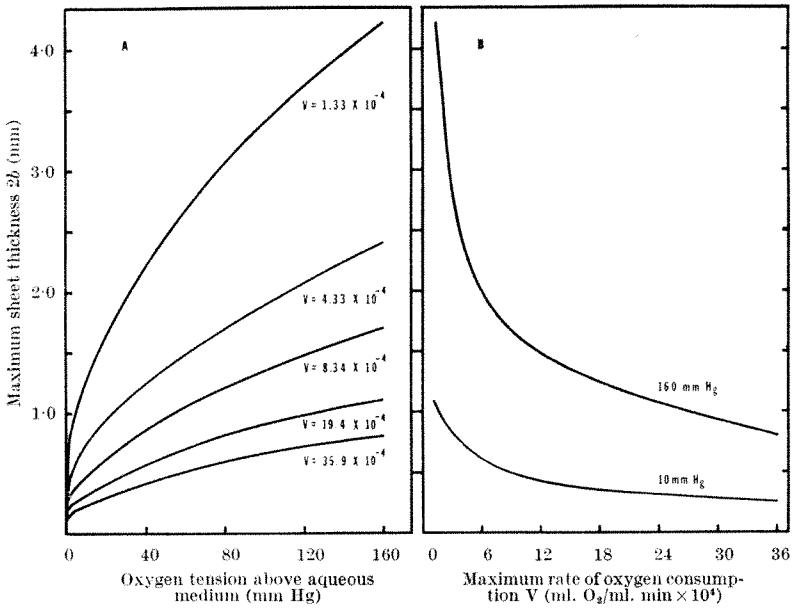

Fig. 1. *A*, Maximum thickness of tissue sheets utilizing oxygen at various rates as a function of oxygen tension above the aqueous medium. *B*, Maximum thickness of tissue sheets as a function of rate of oxygen consumption at a high and a low oxygen tension. Oxygen consumption values were chosen to cover the range of values found in modern diffusion animals[23–25]. The diffusion constant is that of oxygen in muscle at 16°–20° C (4.5×10^{-4} cm²/min)[25].

of atmospheric oxygen content are shown in Fig. 1*A*; some of the data are replotted in Fig. 1*B* to show the maximum thickness as a function of the rate of oxygen consumption. At present day oxygen level, animals of thickness greater than 2 mm are possible only when oxygen consumption rates are very low. At a primitive oxygen level of 10 mm Hg, which, as discussed below, may have been sufficient for the evolution of a more advanced respiratory system, organisms of 1 mm in thickness are possible only at the lowest rate of oxygen consumption treated. Under low oxygen tensions (2–10 mm Hg) and at consumption rates typical of many modern diffusion animals, the thickness is limited to 0·1–0·5 mm. Indeed, many modern diffusion animals (for example, planarians, polyclads and coelenterates[9,13]) are constructed as sheets with a thickness of less than 1 mm. Coelenterates are larger on account of their construction—the mass of the body is the thick non-cellular or poorly cellularized mesoglia which acts as a metabolically inert, low density skeleton on which the actively metabolizing thin sheet of tissue is spread[14,15].

Thus in conditions of low oxygen tensions, active diffusion animals with structures other than the evolutionarily limited medusoid or polypoid pattern would have been very small. The small size and soft-bodied construction of such animals explains their lack of preservation in the fossil record[16].

The ancestral metazoa, by depending on the diffusion of oxygen from the environment to their cytochrome oxidase system, were therefore necessarily limited in size. Any increase in size necessitated the evolution of a circulatory system. This could only have occurred when the atmospheric oxygen content increased to such a point that a sufficient gradient existed to allow the function of a transport pigment. Modern oxygen transport pigments capable of operating at very low oxygen tensions are known from aerobic mud-burrowing organisms existing in oxygen-poor environments[17]; for example, the polychaete annelid, *Arenicola marina*, and the sipunculid, *Siphonosoma ingens*. The concentration of dissolved oxygen in the interstitial water surrounding the burrows of *Arenicola* corresponds to an oxygen tension of 6·7 mm Hg at 15° C and, in the burrows, of 13·4 mm Hg. There is evidence that the worm can respire at this oxygen tension[18,19]. *Siphonosoma* lives in muddy sand in burrows a foot or more below the surface: these burrows are well defined, but have no detectable connexion to the surface. The organism obtains oxygen from the water in the burrows. The oxygen equilibrium curves of the respiratory pigments of these worms are plotted in Fig. 2, along with the oxygen consumption curve of yeast[20] as an example of a typical cytochrome oxidase system. These pigments operate at oxygen tensions from 3–10 mm Hg and both unload to a significant extent at oxygen tensions above the *Km* of cytochrome oxidase. We are not proposing that primitive transport pigments necessarily resemble the pigments of these worms; rather, these pigments serve as examples of transport systems which operate at low oxygen tensions. The existence of such pigments suggests, however, the possibility of the evolution of circulatory systems when the oxygen tension of the atmosphere increased to about 3–10 mm Hg (depending on the permeability characteristics of the skin of the animal).

We suggest therefore that the earliest metazoa must have been diffusion animals without circulatory systems and constructed on either the coelenterate or flatworm plan[15,21]. The flatworms were probably ancestral to the other major phyla. Only when the atmospheric oxygen tension increased to a level sufficient for the evolution of a circulatory system would it have been possible for the evolution of diverse bodily organizations, large sizes and shells or exoskeletons. When the required level of oxygen was attained is, of course, not known[1,4,22], but it must have occurred long enough before Ediacara times for the evolution of quite complex annelid worms to have taken place.

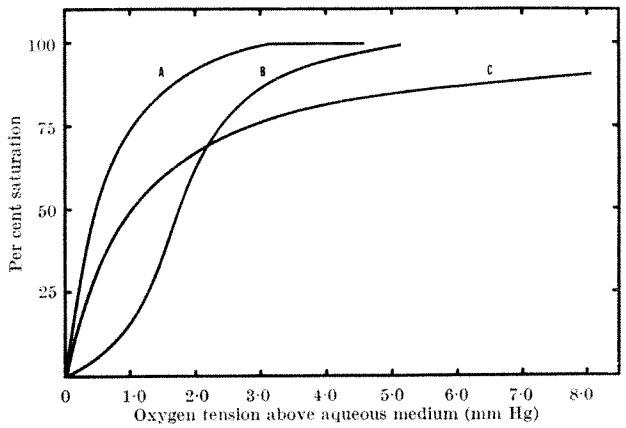

Fig. 2. Oxygen saturation curves for (*A*) yeast cytochrome oxidase[20], (*B*) *Arenicola* haemoglobin[18], and (*C*) *Siphonosoma* haemerythrin[26].

Biosynthesis of Monoterpenes in Rose Flowers

ALTHOUGH mevalonic acid (MVA) is generally assumed to be an obligatory precursor of terpenes in higher plants, incorporation of 2-^{14}C-MVA into the principal monoterpenes of numerous species is almost invariably less than 1 per cent (ref. 1). Monoterpene biosynthesis is nevertheless assumed to occur via conversion of MVA into isopentenyl pyrophosphate (IPP) and 3,3-dimethylallylpyrophosphate (DMAPP) which condense to form, directly or in sequence, geranyl or neryl pyrophosphates (GPP and NPP), the presumed precursors of straight chain and cyclic monoterpenes respectively. More than 80 per cent of the total label from 2-^{14}C-MVA, however, has been found to pass into that part of several thujane derivatives[2], camphor[3], pulegone[4] and artemisia ketone[4], and of certain sesquiterpenes[5] also, which was derived from IPP. In only one example[6] has a monoterpene, other than a methyl cyclopentanoid monoterpene, biosynthesized from 2-^{14}C-MVA by a higher plant been shown to contain radioactivity comparably distributed between the moieties derived from IPP and DMAPP. All these experiments involved feeding leaf and stem tissue for 1–5 days, and less than 0·1 per cent of the applied tracer was incorporated during this period.

Excellent evidence for the accepted pathway has been provided by the recent discovery that within 1 h of feeding the hybrid tea rose 'Lady Seaton' with 2-^{14}C-MVA, up to 11 per cent of the total label becomes incorporated into certain monoterpenols and their β-glucosides found in the petals[7–8]. It is therefore important to determine the pattern of 2-^{14}C-MVA incorporation in these monoterpenols. Flower-heads of 'Lady Seaton' hybrid tea rose (8 days after initial splitting of the calyx; preperfect stage, see ref. 8) were incubated with the dibenzylethylenediamine salt of 2-^{14}C-MVA (5 μCi; 0·23 mg per flower head) or the potassium salt of either 2-^{14}C-(4*S*)-4-^{3}H-MVA or 2-^{14}C-(4*R*)-4-^{3}H-MVA (between 1·5 μCi and 1·0 μCi ^{3}H and 0·5 μCi ^{14}C; 0·2 mg) for 1 h after starting the MVA infusion and geraniol and nerol occurring both free and bonded as β-glucosides were isolated[8,9]. Some 2·5 to 5 per cent of the applied 2-^{14}C-MVA was incorporated into these monoterpenols. The monoterpenes were purified by preparative gas-liquid chromatography and the ^{14}C-containing material was oxidized to citral and thence ozonized to form oxalic acid, levulinic acid and acetone. Levulinic acid was converted into iodoform and succinic acid, and the latter was decarboxylated by a Curtius rearrangement[10]. Acetone was degraded by the iodoform reaction. All degradation products were isolated as solid derivatives and recrystallized. The doubly labelled monoterpenes were purified by gas-liquid and column chromatography and by complexing with calcium chloride.

Geraniol obtained from the glucoside after 2-^{14}C-MVA feeding gave citral, levulinic acid and acetone with specific activities (d.p.m./mmole) of 86,620, 44,680 and 43,940. Further degradation revealed no tracer at C1, C2, C3, C6, C7 or C9 (Fig. 1, *trans*-CH_2OH) and the tracer was equally distributed between (C4 + C5) and (C8 + C10). On biogenetic grounds the location can be assigned to C4 and C10, though isomerization of C8 and C10 is observed in some monoterpenes biosynthesized from MVA by way of geraniol[11]. Nerol from the analogous source gave citral, levulinic acid and acetone with specific activities of 17,390, 8,098 and 9,473 respectively and again it is inferred from the degradation that the tracer is equally distributed between C4 and C10 (Fig. 1, *cis*-CH_2OH).

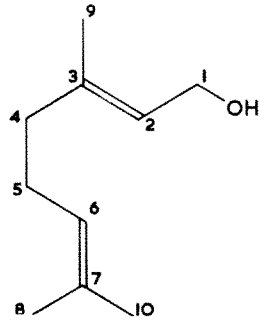

Fig. 1.

The isomer, 2-^{14}C-(4*R*)-4-^{3}H-MVA, was fed at a ^{3}H, ^{14}C ratio of 1·99 and the (4*S*)-isomer at a ratio of 1·25. The isotope ratios in free geraniol recovered after feeding the (4*R*) and (4*S*)-isomers were 1·96 and 0·04, and for geraniol from the β-glucoside were 1·97 and 0·05. The isotope ratios in nerol from the β-glucoside were 2·21 and 0·09 after feeding the (4*R*) and (4*S*)-isomers and for the free nerol from the (4*R*)-isomer was 2·20.

Three points emerge from this work. First, 2-^{14}C-MVA was incorporated into both free and bonded monoterpenes of rose petals in a highly position-specific fashion so that tracer was equally distributed between the moieties derived from IPP and DMAPP. Second, direct condensation of IPP and DMAPP to NPP (and subsequently to nerol) would lead to the loss of the (4*R*)-H of MVA, whereas condensation to GPP and isomerization to NPP would lead to loss of (4*S*)-H. This can be inferred from several studies of the incorporation of ^{3}H, ^{14}C-labelled MVA into higher terpenes[12]. Our results, the first with geraniol and nerol, the presumed precursors of all other plant monoterpenes, indicate the latter route and are consistent with parallel ^{3}H, ^{14}C studies on α-pinene from *Pinus attenuata* (unpublished results of G. Ayrey, D. V. B., D. Barnard and G. N. J. Le P.). The direct trans-cis isomerization of the 2–3 double bond of geraniol (or of a geraniol derivative) must therefore occur; such an isomerization is an uncommon biochemical reaction and further work on the mechanism of this reaction will be of interest. Third, previous conclusions[12] are confirmed, that the (4*S*)-H of MVA is lost in the isomerization of

IPP into DMAPP in higher plants, as in yeast and mammalian tissue.

The first conclusion differs from that obtained in previous investigations of monoterpene biosynthesis in leaf and stem tissue, excluding the methylcyclopentanoid monoterpenes. The existence of a metabolic pool of DMAPP, a non-MVA source for this compound, or the operation of appropriate compartmentation effects can explain the previous labelling results: presumably such factors do not operate in petals. Thus leaf and stem tissue contain discrete oil glands not seen in petal tissue.

Short Term Test for Evaluating Potential Carcinogenic Activity of Tobacco Condensates

Mouse skin has been used for many years as a convenient tissue for the assay of tumorigenic properties of tobacco condensates. This testing is prolonged and expensive, and the value of the results obtained is controversial; it is therefore desirable to find a way of shortening the experimental procedure. Sebaceous glands provide a convenient route of entry for substances painted on to the skin, and in particular for the lipid soluble carcinogenic hydrocarbons found in tobacco condensates, which can, in fact, be labelled and located in these glands. Polycyclic hydrocarbons in particular have been used to demonstrate the possibility of using destruction of sebaceous glands to indicate potential carcinogenic activity, and Bock and Mund[1,2] showed that if compounds with a benzanthracene structure are used the degree of destruction is related to tumorigenic activity. Unfortunately, some carcinogenic substances in which the benzanthracene structure is absent (for example, 7,9-dimethylbenz(*c*)-acridine) do not destroy the sebaceous glands; but this does not apply to tobacco condensates[3].

The development of image analysers[4,5] which can rapidly calculate area size of oddly shaped structures, and of reliable enzyme histological methods, have solved the main problems of analysing gland suppression data. The new technique involves the demonstration of non-specific esterase enzymes in the skin of mice painted with tobacco condensates or other carcinogenic hydrocarbons, and the evaluation of areas covered by this enzyme. Non-specific esterase demonstrated by the indoxyl-acetate method of Holt[6] seems to be confined to the sebaceous glands and a few nerve fibres.

Groups of 12 SPF mice (CFLP) each 50 days old to avoid the complication of cyclic hair growth changes were painted on three consecutive days with various doses of three different tobacco condensates and various other potentially carcinogenic substances. Four days after application of the final dose all the mice were killed and a piece of skin from the painted area was frozen in hexane pre-cooled to −75° C. Twelve 40 μm cryostat sections were cut transversely from each piece of skin, fixed in formol–calcium–gum–sucrose and non-specific esterase enzyme demonstrated as described. The total area of reaction product contained in 3,000 fields (each measuring 68,000 μm²) from each group of animals was measured with a 'Quantimet B' image analyser. The reading took about 2 h per group, all the groups being read by an operator with no prior knowledge of which compound had been painted. Results (Table 1) show a direct relationship between area of enzyme activity and known carcinogenic activity of the compound. All the tobacco condensates were ranked in dose and tumorigenic order as previously established by long term tumour production methods.

Table 1. RELATIONSHIP OF AREA OF ENZYME ACTIVITY TO KNOWN CARCINOGENIC ACTIVITY

Compound	Dose	Area (μm²) of esterase activity (mean of 3,000 fields)	Tumour yield from long term tests (80 weeks*) per cent
Tobacco condensate A	36 mg	156	38
A	60 mg	64	48
A	100 mg	36	77
B	36 mg	450	12
B	60 mg	348	32
B	100 mg	63	33
C	36 mg	522	8
C	60 mg	339	25
C	100 mg	99	27
DMBA	250 μg	51	—
Urethane	25 mg	1,392	—
Acetone (solvent) control (1)	0·33 ml.	2,796	—
Acetone (solvent) control (2)	0·33 ml.	2,549	—
Croton oil	0·1 per cent	2,067	

* Age standardized.

DMBA = 9,10-dimethyl-1,2-benzanthracene (Sigma).

This test is not entirely specific for carcinogenic activity and probably relates more to the toxicity of the painted substance to the sebaceous gland cells. It is, however, remarkable that within the range of substances tested this toxicity is directly related to carcinogenicity; and it seems therefore to be a useful rapid screen for potential carcinogenic hazards in tobacco condensates.

Correspondence

Milk Secretion

SIR,—Professor Patton (*Nature*, **228**, 97; 1970) seems to think it absurd that we should have reported that we had detected pieces of secretory cell cytoplasm in goats' milk (Wooding, Peaker and Linzell, *Nature*, **226**, 762; 1970) because the quantity is so tiny that it could have no bearing on theories of cellular mechanisms involved in milk secretion. According to this view only the major component, water, is worthy of study! I think our finding is of biological significance because:

(1) It settled a controversy. Bargmann, one of the first to examine mammary tissue with the electron microscope, specifically rejected the old idea of classical histologists that some cytoplasm is shed (apocrine secretion) although he proposed that fat globules are pinched off with cell membrane around them. Patton published impressive chemical evidence purporting to support this, and theoretical calculations of London–van der Waals forces to show why the cell membrane only would be expected to be shed with the fat. These views were widely accepted, by myself as well, until, in reviewing the subject, we found four papers on mammary ultrastructure supporting apocrine secretion. These papers have not been quoted by Patton's group. We also were doubtful and to decide whether pieces of cytoplasm were undoubtedly detached from the cell we examined milk in the electron microscope and found a small proportion of fat globules had sizable pieces of cytoplasm attached to them ("signets"), confirming Kurosumi's view that mammary secretion is partly apocrine. However, most unexpectedly we found a very few much larger pieces of cytoplasm, which were packed with active organelles, but lacked a nucleus. These could have been produced by cell decapitation as the apocrine theory predicted. I agree that the bulk of milk is unlikely to be derived from shed cytoplasm, but Professor Patton's protest reminds me of the nurse in *Midshipman Easy* (F. Marryatt, 1836) who, excusing her illegitimate baby, said, "If you please ma'am, it was a very little one".

(2) It should change attitudes. One must now be cautious in entirely discrediting the apocrine mechanism. Although the numbers are small the "signets" can hardly be dismissed as débris, as Professor Patton does. We have now found them in the milk fat of all species examined (cow, sheep, guinea-pig, rabbit and most abundantly in the wallaby), although there were interesting variations in the number of free cytoplasmic fragments, which were frequent in the goat but few in the cow, and whole secretory cells were found in the guinea-pig. The fact that wallaby milk was rich in "signets" may suggest that in more primitive mammals the apocrine mechanism was the basic one, which was later superseded during evolution by the mechanism producing the aqueous phase of milk. The mechanism involved in milk secretion is also relevant to another controversy, whether mammary glands evolved from sweat or sebaceous glands, because apocrine processes are also involved in sweat production.

Radiation from Ball Lightning

SIR,—In a recent communication (*Nature*, **228**, 545; 1970) Altschuler and his colleagues suggest that the phenomenon of ball lightning may be due to formation of the short-lived radioactive nuclides ^{15}O and ^{17}F within a localized plasma capable of yielding radioactive decay energy of the order of 10^7 J. It can readily be shown that the mean γ-ray absorbed dose-rate in a human body at 2 m distance from such a radiation source, if unshielded, would be about 175 rad s^{-1} for ^{15}O or 325 rad s^{-1} for ^{17}F. With dose-rates of this magnitude it would be surprising if there had not been reports of close observers developing signs of radiation sickness. Some may even have received lethal exposures. It is therefore suggested that medical evidence of radiation effects should be sought in persons who have witnessed ball lightning at close quarters. As an alternative approach to testing the proposed theory, however, it would seem profitable to examine, for evidence of high radiation dose, the thermoluminescent properties of any ceramic or other appropriate mineral material in the vicinity of a suspected ball lightning strike.

Uranium Supplies

SIR,—The figures quoted from the ENEA report on uranium resources (*Nature*, **228**, 306; 1970) are much the same as those circulated by various sources in 1967.

The need for exploration and development of new reserves was also widely stressed in 1967–68. However, the last two paragraphs of your item really underline how dated is the ENEA report.

Elliot Lake suffered several years of decline in the early 60s, when two-thirds of the houses and other buildings were empty. In 1968, however, all accommodation (except for a few houses under repair) was occupied again, and additional houses were being moved from dead areas into Elliot Lake.

Denison Mines spent some $2·9 million in 1967 on mine and mill improvements; similarly Rio Algom were reactivating old workings and developing new areas. Other operators were also preparing for additional output to meet anticipated demand.

The Canadian mining industry has been calling for years for an intelligent approach by such bodies as the USAEC and the US power authorities to the problems involved in providing a steady supply of uranium, including advance buying and long-term contracts. If the nuclear generating forecasts are accurate, there can be little doubt that there will be a shortage of uranium by 1980.

Definition of Intelligence

SIR,—As a user but non-worshipper of computers, I must take exception to the definition of intelligence, and to the logic employed in the letter entitled "A Definition of Intelligence" (*Nature*, **228**, 97; 1970). As to the suitability of definitions, that is a matter of opinion, but I find Webster's "the capacity to apprehend facts and propositions and their relations and to reason about them" quite satisfactory if not completely explicit. (What dictionary definition is ?)

Furthermore, you will find the authors' definition in the dictionary, under "induction". To quote Webster again, "the act, process, or result, of reasoning from a part to a whole, from particulars to generals, or from the individual to the universal". To give the letter its due, I prefer their definition of "induction" to that of Webster, but it is clear that induction is only one of several skills associated with intelligence.

What is more serious is the failure of logic, "Thus machines . . . cannot be intelligent because the machine's instruction set is a proper subset of man's instruction set".

First, even simple, admittedly non-intelligent computer programs contain instructions which man's brain does not. Second, recent computer program research has produced programming which is able to expand itself. Given rules for induction, deduction, and other "intelligent" processes, these programs expand themselves, generating further instructions on the basis of experience and observation. Third, even granting every statement in the letter, we already know from experience that one man's having a "smaller" instruction set (less intelligence) than another does not mean that such a man is incapable of innovation and intelligent behaviour. Why, then, do the authors assume that a computer has to have a larger set than man in order to innovate, improvise, discover or induce ?

While human beings are obviously more than mere biological computers, I find nothing in their argument, nor in any other I have encountered, which rules out the possibility that, some day, a computer-machine will be constructed which is able to accept a sophisticated, man-invented program, which permits this new life-form to evolve mentally through experience and learning in a manner similar to man, and do this in such a way as to satisfy any reasonable definition of intelligence. Perhaps Norbert Wiener's test of such a machine could be employed. He suggests that any computer candidate plus several men for controls be equipped with typewriters for input and output. Those who would doubt the candidate are required to interview any and all of the unlabelled teletype units by typing in questions to be answered. If the doubters do not do much better than the statistical random probability in pointing out which teletype is connected to the computer, we must conclude that the computer simulates man and displays intelligence.

Yours faithfully,

PAUL M. MULLER

SIR,—Fatmi and Young[1] suggest that "Intelligence is that faculty, of mind, by which order is perceived in a situation previously considered disordered". This is an attractive definition because it opens the way to measures of intelligence that are not based upon comparison with population norms.

Consider a very simple test. To create some disorder, suppose we toss a penny and represent the result as a binary number 0 or 1. Show a subject a sample of these disordered digits, then tell him that you may, or may not, change the method of selecting the digits, and ask him to tell you as soon as he knows whether you have changed it. Because the initial sample was completely disordered, the only change possible is the introduction of order, and if the subject perceives it, he has displayed intelligence by Fatmi and Young's definition.

The amount of order can be measured by the change in information or entropy of the new sample of digits compared with the old. The minimum amount that can be detected would be expected to be inversely related to the strength of the faculty that detects it. Suppose we show only 0s; the maximum amount of order (one bit's worth) has been introduced, and this should be quickly perceived by any subject. If, on the other hand, we slightly bias the penny, this would be more difficult to detect. There may be more to intelligence than the ability to perform such a task; but if it is required for it, one can set out to measure its "threshold" in the same way that one measures the threshold of an eye or ear, namely by measuring the least amount of light or sound that can be detected.

The detection of bias in a coin is a statistical problem, and one can say how many tosses are required to detect a given bias at any confidence level. Thus one could compare a subject's performance with the theoretical ideal, and if he required S tosses to achieve a performance ideally requiring I tosses, then it would be reasonable to say that his efficiency at this task was I/S. This is closely similar to the measure of quantum efficiency that is used to compare photodetectors and human vision, and it provides an absolute scale applicable in a wide variety of situations[2,3].

It is easy to see what is missing from this model; for coin tossing there is really only a single null hypothesis that we can ask a statistician to test, namely "The bias in the second sequence is the same as in the first". With many coins, the number of possible forms of order that can be introduced increases very rapidly indeed, and if the possibility of ordered sequences is introduced the number of possible null hypotheses becomes virtually unlimited.

Fatmi and Young apparently framed their definition in order to distinguish more clearly between machine and human intelligence. However, its real merit may be that it enables one aspect of the intelligence of either mind or machine to be compared with, and measured in terms of, the performance of an ideal detector of order in disorder.

Yours faithfully,

H. B. BARLOW

Department of Physiology,
University of California,
Berkeley, California 94720.

[3] Barlow, H. B., *J. Physiol.*, **160**, 155, 169 (1962).

SIR,—G. Hyde (*Nature*, **228**, 589; 1970) gives a definition of intelligence which is good but not complete, as it cannot be quantified as expressed, nor lead to such quantification.

A simpler yet more complete definition is "intelligence is the capacity to understand".

It may be possible at some time to quantify this capacity, which does not need linguistic behaviour for its definition.

Geological Semantics

SIR,—More than fifty years ago, Professor Crum Brown coined the word 'kerogen' (Greek = wax producer) to denote, exclusively, the oil-yielding component of oil shale. Regrettably, 'kerogen' is now being applied to the insoluble organic matter of rocks in general, and its original usefulness appears to be lost. Reference to the early literature shows also that the word 'sporopollenin' was invented to specify another indefinite mixture of insoluble matter; in this case, a major portion of exines. During a recent conference on sporopollenin, it was suggested that the meaning of this term be also widened. A research paper has now suggested that some kerogens can be identified with sporopollenin and this, in turn, may be considered as polymerized carotenoids.

Until a decade ago, one could use the word 'kerogen' with significance, although, as Carlson has stated, "one does not presume to attribute to kerogen itself any certain composition, but recognises that it is made up of a mixture of organic debris in varying proportions". Unfortunately, some contemporary research appears to be based on the imprudent assumption that, in kerogen, a singular molecular genus is involved. This, of course, is not true; kerogen, by any acceptable definition, can never be considered more than a vague mixture of partially lithified organic residuals. Simple microscopic examination will reveal this point.

An undesirable semantic trend is apparent. Initially, 'kerogen' was a term with explicit application but covering obscure organic matter in certain rocks. Today, the interpretation is equivocal but the substance has acquired a chemical identity entirely out of keeping with its actual nature and origin.

Theories of Electromagnetism

SIR,—The difference between Stopes-Roe (*Nature*, **228**, 193; 1970) and myself (*Nature*, **227**, 935; 1970) is less a question of fact than of what we consider has fundamental importance. We agree that the influence of a surrounding medium on the field of a magnet depends on the shape of that magnet. We also agree that for the special case of the historically important long thin magnet immersed in a magnetic medium, the Kennelly formulation is correct and the Sommerfeld formulation is incorrect.

The difference seems to be that Stopes-Roe thinks that formulae applying to long thin magnets are still fundamentally important in the theory of electromagnetism while I regard them as applying to a rather trivial special case. The inverse square law for a point pole is still important, however, provided it is not regarded as a real point pole, but as a small element in a distribution of poles. These poles may be distributed over a large surface or even a volume, but provided the distribution of poles is known, **H** can be calculated both in free space and inside the magnet itself, where it is the self-demagnetizing field. The latter is independent of the permeability of the magnet except in as far as that permeability affects the pole distribution. Alternatively one may use the inverse cube dipole law and the distribution of dipoles, and, of course, in either case the appropriate scalar potentials can be introduced with advantage.

The point is that these formulae predict the field due to a magnet of any shape or size for which the distribution of magnetization is known provided that the magnet is situated in free space. In this integral form these magnetic laws are practically useful and have some claim to be regarded as fundamental laws comparable with Biot–Savart's law for the field due to an element of an electric circuit, the usefulness of which is not that it predicts the field produced by a very small circuit, but can be integrated to predict the field due to any circuit.

Thus the purpose of my letter was to show that the classical laws for **H** due to small poles or dipoles are of fundamental importance because they can be integrated to give **H** due to a magnet of any shape or size, but if the relative permeability μ_r of a medium surrounding the magnet is introduced the integration is invalid except for certain special cases such as the long thin magnet.

The only valid solution appears to be to extend the integration to include the poles or dipoles induced in the surrounding medium. It would be premature to write further on this subject at present, and it is unlikely that it could be adequately treated in a short letter.

Yours faithfully,

M. MCCAIG

Sheffield S1 1FA.

Obituaries

M. G. M. Pryor

THE scientific career of Mark Pryor, who died on October 19, 1970, was tantalizingly incomplete. A born naturalist, a more than competent botanist and knowledgeable entomologist, interested particularly in freshwater biology, his contributions to knowledge were mainly on the borderline between biophysics and biochemistry.

After gaining a first class in both parts of the natural sciences tripos at Cambridge, Pryor was a research student under A. D. Imms and produced a thesis which completely revolutionized our conception of the insect cuticle by demonstrating that the dark and horny component, "sclerotin", the nature of which had been a puzzle for a century or more, was essentially protein tanned by quinones generated *in situ* by the enzymic oxidation of diphenols. This theory, of course, was incomplete; we now know that there are other forms of polymerization going on at the same time; but it is still the basis of our understanding of the arthropod cuticle. Indeed, the same process is widespread, from the egg-shells of helminths to the capsules of skates and dogfish.

Pryor was elected to a fellowship of Trinity College in 1939. On the outbreak of war he promptly enlisted. But it was not long before he was pulled out of the army and transferred to the Timber and Adhesives Division of the Royal Aircraft Establishment at Farnborough, where his deep interest in plastics and polymers had every opportunity to develop. It was here that he conceived a highly original theory of muscle as a heat engine, according to which it was supposed that in the resting state the myosin fibres were closely aligned and stabilized by mutual attraction and that ATP acted as

a "plasticizer", weakening the attraction between the protein molecules and leaving them free to curl up under the influence of thermal agitation and so cause the muscle to contract. On his return to Cambridge to take up his fellowship after the war Pryor threw himself into the proving of this hypothesis by experiment and by thermodynamic analysis. He put in an immense amount of work, the published accounts of which are still worth reading. But in the end his theory failed to take the stage. The sliding filament model won the day.

In 1955 Mark Pryor became a tutor in his college and was later senior tutor until 1964. Then once more he became free to devote time to laboratory work. His mind was still as lively, alert and original as ever. He was determined to climb back into research. He kept before him the example of A. V. Hill, with whom he had had much friendly contact during the muscle days. And in spite of taking on heavy teaching duties for the new course of cell biology, he would surely have succeeded but for the tragic accident which brought his life to an untimely end.

Mr W. C. S. Wigley

MR W. C. S. WIGLEY died in October at the age of eighty. He made important contributions to the science of ship hydrodynamics by bringing together mathematical theory and experiment and his work is still having a profound effect on ship design.

As a scholar of Emmanuel College, Cambridge, he completed the Mathematical Tripos in 1912 with considerable distinction. After the war he joined what was known as the "Tank Department" of the National Physical Laboratory, where, for many years, he pioneered work on ship propeller design and mathematically defined hull forms for research purposes. In 1927, a paper on the mathematics of wave resistance to ships earned him a Premium of the Institution of Naval Architects and in 1941 he was awarded the Gold Medal of the institution. His work at this time led to an understanding of the action of the bulbous bow in reducing the wave resistance to a ship and to the adoption in many countries of large and strangely shaped bulb and ram bows. After 1946 he worked as a consultant to the Admiralty and the United States Navy. Many of his later studies of ship resistance and stability problems remain unpublished and are known only to those who commissioned them.

Mr Wigley became a member of the Royal Institution of Naval Architects in 1926. He was an Associate Member of the Council from 1942 and in 1967 he was elected a vice president. In the same year he was awarded the MBE.

Mr Wigley enjoyed railways and country walks and spent much time making genealogical searches of West Country church registers. He is remembered as a man of retiring disposition but of fiery and highly individual spirit too. He remained a bachelor throughout his life.

Announcements

University News

Professor J. E. Dowling, Johns Hopkins University School of Medicine, has been appointed professor of biology at **Harvard University.**

Dr A. J. Meadows has been appointed to a personal professorship of astronomy in the **University of Leicester.**

The following appointments have been made in the **University of London: Dr G. W. Bisset** to the chair of pharmacology at St Thomas's Hospital Medical School; **Dr M. Guter** to the second chair of chemical engineering at University College; **Dr N. A. Mitchison** to the Jodrell chair of zoology and comparative anatomy at University College; **Professor B. R. Rabin** to the chair of biochemistry at University College; **Dr G. F. M. Russell** to the chair of psychiatry at the Royal Free Hospital School of Medicine; **Mr. G. N. Walton** to the chair of nuclear technology at Imperial College; **Professor M. H. F. Wilkins** to the chair of biophysics at King's College; **Dr R. P. Dales** to the chair of zoology at Bedford College.

Dr J. D. M. Wright, University of Oxford, has been appointed professor of pure mathematics at the **University of Reading.**

Dr L. L. Cavalli-Sforza, director of the Institute of Genetics, University of Pavia, has been appointed professor of genetics at **Stanford University School of Medicine.**

Dr G. H. Giebisch has been appointed Sterling professor of physiology and **Dr A. J. Solnit** professor of pediatrics at **Yale University.**

Appointments

Mr C. D. Colchester has been appointed chief scientist to **Marconi Radar Systems Limited.**

Dr D. J. Littler has been appointed controller of research of the **Central Electricity Generating Board.**

Dr G. P. Murphy has been appointed director of the **Roswell Park Memorial Institute,** operated by the New York State Department of Health.

The **Atomic Energy Board of South Africa** has been reconstituted, and now includes the following members: **Mr J. W. Shilling; Dr G. S. J. Kuschke; Mr H. S. Mabin; Mr J. P. Coetzee; Mr C. J. F. Human; Dr S. M. Naudé; Dr R. L. Straszacker; Professor S. F. Dosthuizen; Mr N. J. Uys; Mr B. G. Fourie.**

Miscellaneous

Dr Pierre Deslongchamps, University of Sherbrooke, has been awarded the **E. W. R. Steacie memorial fellowship** for 1971–72 by the National Research Council of Canada.

The **US Institute of Electrical and Electronics Engineers group award** for 1970, presented in memory of Samuel A. Talbot, has been won by **Dr William S. Rhode,** University of Wisconsin.

Brigadier Ralph A. Bagnold has been awarded the **Penrose medal** by the Geological Society of America, in recognition of his work on the formation and movement of sand dunes.

Applications are invited by the council of St John's College, Cambridge, for a **Meres senior studentship** for medical research. The Meres student must be a university graduate and must carry out his research in the University of Cambridge or nearby. The studentship is tenable for between 1 and 3 years. Further information can be obtained from the master of St John's College, Cambridge CB2 1TP.

A travelling scholarship worth **£300** is offered by the **Institute of Electrical and Electronics Engineers** for visit(s) by a postgraduate student to foreign electrical or electronic research or manufacturing establishments. Candidates must submit a proposed programme of visits,

and the award will be made for the programme judged most likely to foster a closer relationship between young engineers in different countries. Further information and entry forms can be obtained from Dr J. A. Ellison, Queen Mary College, Mile End Road, London E1 4NS.

An annual prize of £250 will be awarded by the **Nutrition Society,** in memory of the late Sir **Jack** Drummond, for research in nutrition. Candidates should be less than 40 years of age and normally resident in the United Kingdom. Further information can be obtained from Dr G. L. S. Pawan, Metabolic Division, Department of Medicine, the Middlesex Hospital Medical School, London W1P 7PN. The closing date for applications is February 1, 1971.

An award of £50 will be made every two years by the board of the **British Cryogenics Council** for some outstanding contribution to cryogenics in the United Kingdom, through the discovery of a new phenomenon or the development of a new process. Applications for the period January 1969 to December 1970 should be submitted by February 20, 1971. Further information can be obtained from the honorary secretary of the British Cryogenics Council, c/o The Institution of Chemical Engineers, 16 Belgrave Square, London SW1.

The following new academicians have been elected to the **Academy of Sciences of the Soviet Union: V. S. Vladimirov** (mathematics); **B. B. Kadomtsev, Yu. B. Kobzarev, I. M. Lifshits** (general physics and astronomy); **A. N. Skrinskii, P. A. Cherenkov** (atomic physics); **L. R. Neiman, V. M. Turkevich** (technological problems of power and energy); **A. A. Voronov, N. I. Isanin, N. N. Yanenko** (mechanics and control processes); **Ya. M. Kolotyrkin, I. Ya. Postovskii** (general and technical chemistry); **A. V. Novoselova, V. D. Sadovskii** (physical chemistry and inorganic technology); **A. A. Baev, Yu. S. Ovchinnikov, A. S. Spirin, M. N. Livanov, S. S. Shvarts** (biology and biochemistry); **Yu. A. Kosygin, V. A. Kuznetsov, F. V. Chkhrov, N. A. Shilo** (geology and geophysics); **K. K. Markov, A. M. Obukhov** (oceanology, atmosphere physics and geography); **B. B. Piotrovskii** (history); **A. N. Efimov** (economics); **D. S. Likhachev** (literature and linguistics). Seventy-two corresponding members of the Academy were also elected.

ERRATUM. In the article "Selection and Covariance" by G. R. Price (*Nature*, **227**, 520; 1970), z and $\bar{z}_M$ in the last term of equation (5) should be numbers of daughters conceived by males, instead of total offspring conceived by males.

ERRATUM. In the article "The Function of Dislocations in Cell Walls and Membranes" by W. F. Harris and L. E. Scriven (*Nature*, **228**, 827; 1970), the last two sentences in column 1, page 828, should become "For positive growth, vacancies are required for the accommodation of protomers. A dislocation in a sense provides an inexhaustible supply of vacancies[12]. In negative growth, dislocation provides removable protomers without leaving vacancies in the crystal".

International Meetings

December 15, **Electrode Kinetics and Processes involving Solid Electrolytes,** London (B. Steele, Metallurgy Department, Imperial College, London SW7).

January 5–7, 1971, **The Impact of New Techniques on Palaeontology,** Belfast (Dr A. D. Wright, Department of Geology, The Queen's University, Belfast BT7 1NN, Northern Ireland).

January 24–30, 1971, **Clifford Algebra, its Generalization and Applications,** Ootacamund (Professor Allaid Ramakrishnan, Institute of Mathematical Sciences, Madras 20, India).

British Diary

Monday, December 7

Change or Decay (6.30 p.m.) Mr J. K. Wood, Institution of Electrical Engineers, at the Town Hall, Chester.

Dental Decay, Dental Care and Chemistry (6.30 p.m.) Dr G. S. Ingram, Society of Chemical Industry, at 14 Belgrave Square, London SW1.

Electrical Aspects of Spacecraft (7 p.m.) Mr H. J. Sketch, Institution of Electrical Engineers, at Grimsby College of Technology.

Invention as Part of Education (7 p.m.) Professor W. M. Thring, Institution of Electrical Engineers, at the Royal Star Hotel, Maidstone, Kent.

Some Aspects of TV Reception from Satellites (7.30 p.m.) Mr K. G. Freeman, Institution of Electrical Engineers, at BBC Training Centre, Wood Norton, Evesham.

The Michelson-Morley Experiment (5.30 p.m.) Dr E. Zahar, British Society for the Philosophy of Science, in the Joint Staff Common Room, University College London, Gower Street, London WC1.

The Report of the Marshall Committee (5.30 p.m. discussion) Institution of Civil Engineers, at Great George Street, London SW1.

The Value of Gel Permeation Chromatography for the Design of Alkyd Resins (7 p.m.) Mr H. Olley and Dr L. A. O'Neill, Oil and Colour Chemists' Association, at Hull College of Technology.

Tuesday, December 8

Digital Inverse Filters (7 p.m.) Mr J. A. Baker, Institution of Electrical Engineers, at the University, Bradford.

Flavour Analysis with Humans, Instruments and Computers (6.15 p.m.) Professor E. von Sydow, Society of Chemical Industry, Food Group, in the Wellcome Lecture Hall, Royal Society, 6 Carlton House Terrace, London SW1.

Interaction of Cardiovascular Reflexes (5.30 p.m.) Professor M. de Burgh Daly, University of London, at the Institute of Child Health, 30 Guilford Street, London WC1. (Fourteenth of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

International Locust Research and Control (5.15 p.m.) Mr P. T. Haskell, Royal Society of Arts, Commonwealth Section, at John Adam Street, London WC2. (John Curtis "Woodstock" Lecture.)

Microwave Acoustics (6.30 p.m.) Professor K. W. H. Stevens, Institution of Electrical Engineers, at Farnborough Technical College, Farnborough, Hants.

Poverty in Britain (1.15 p.m.) Professor R. Titmuss, University of London, at Queen Elizabeth College, Campden Hill Road, London W8.

The Choice of Industrial Drives to 100 hp (6.15 p.m.) Mr A. F. Wilkinson, Institution of Electrical Engineers, at UMIST, Manchester.

The Significance of Bill Form in the Spoon-billed Sandpiper *(Eurynorhynchus pygmeus)*, Dr P. J. K. Burton; **Locomotion of Worms,** Dr M. K. Seymour; **The Seals of Macquarie Island** (film) (5 p.m.) Zoological Society of London, at the Zoological Gardens, Regent's Park, London NW1.

Tolerances in Building Construction (6 p.m. discussion) Institution of Mechanical Engineers, Joint Building Group, at 1 Birdcage Walk, London SW1.

X-ray Astronomy (1.20 p.m.) Professor R. L. F. Boyd, University of London, in the Botany Theatre, University College London, Gower Street, London WC1.

Wednesday, December 9

Alaskan Exploration and the Development of the Prudhoe Bay Oilfield (5 p.m.) Mr R. Stoneley, Mr A. N. Thomas and Mr M. W. Clegg, Geological Society, at Burlington House, Piccadilly, London W1.

Earth Station Installation Projects (6 p.m.) Mr W. B. Hopkins and Mr N. Wheatley, Institution of Electronic and Radio Engineers, Communications Group, at 9 Bedford Square, London WC1.

Industrial Effluent (7 p.m.) Mr C. Lumb, Society for Analytical Chemistry North of England Section, jointly with the Huddersfield Section of the Royal Institute of Chemistry and the Yorkshire Section of the Society of Chemical Industry, in the Lecture Theatre, Huddersfield College of Technology, Huddersfield.

Large Scale Direct Conversion Power Generation (6.45 p.m., convention) Institution of Electrical Engineers, at UMIST, Manchester.

Marine Fouling (3 p.m.) Oil and Colour Chemists' Association, Newcastle—Student Group, at Newcastle Polytechnic, Ellison Place, Newcastle upon Tyne.

Mersenne's "Harmonie Universelle", 1636-37 (1 p.m.) Dr A. C. Crombie, Royal Institution, History of Science Discussion Group, at 21 Albemarle Street, London W1.

Nuclear Power Today, Tomorrow and the Day After (6.30 p.m.) Mr G. R. Bainbridge, Institution of Electrical Engineers, jointly with Chelmsford Engineering Society, at King Edward VI Grammar School, Chelmsford, Essex.

One World—The Future (5.30 p.m.) Professor B. G. Maegraith, University of London, at the London School of Hygiene and Tropical Medicine, Keppel Street, London WC1 (Last of four Heath Clark Lectures).

Specifications—Do We Need Them? (6 p.m., panel discussion) Society of Environmental Engineers, in the Mechanical Engineering Department, Imperial College, London SW7.

The Environmental Revolution (5.30 p.m.) Mr E. M. Nicholson, University of London, in the Botany Theatre, University College London, Gower Street, London WC1.

The Human Necessity for Automation (6.30 p.m.) Mr P. L. Taylor, Institution of Electrical Engineers, at the University, Sheffield.

The 2-Stage Rotary Engine as a New Concept in Diesel Power (6 p.m.) Institution of Mechanical Engineers, jointly with the Society of Automobile Engineers of America, at 1 Birdcage Walk, London SW1.

Thursday, December 10

Active Transport of Salts and Water in Living Tissues (two-day discussion meeting) Royal Society, at 6 Carlton House Terrace, London SW1.

Addition Copolymers of the Vinyl Ester of Branched Chain Fatty Acids for Use in Electrodeposition Paints (7 p.m.) Dr W. J. van Westrenen and Mr W. H. M. Nieuwenhuis, Oil and Colour Chemists' Association, at East Ham Technical College, High Street South, London E6.

Clinical Aspects of Ultrasonic Diagnosis (10 a.m.) British Medical Ultrasonics Group, in the Barnes Hall of the Royal Society of Medicine, 1 Wimpole Street, London W1.

Development of Gloss Paints in the Twentieth Century (6 p.m.) Mr I. R. McCallum and Mr M. Devine, Oil and Colour Chemists' Association, at the St. Enoch Hotel, Glasgow.

Microelectronics (7.30 p.m.) Mr Newham, Institution of Electronic and Radio Engineers, Scottish Section, at Robert Gordon's Institute of Technology, Schoolhill, Aberdeen.

Modern Trends in Traffic Control (7.30 p.m.) Mr D. G. Hornby, Institution of Electrical Engineers, at Stevenage College of Further Education, Stevenage, Herts.

Nuclear Power Station Construction (7.45 p.m.) Mr K. J. Broome, Institution of Electrical Engineers, at the Castle Hotel, Taunton.

Recent Trends in Oscilloscope Technique (6 p.m.) Mr B. Ellison, Institution of Electronic and Radio Engineers, Instrumentation and Control Group, at 9 Bedford Square, London WC1.

Self-poisoning and Suicide (5.30 p.m.) Professor N. Kessel, University of London, at the Institute of Child Health, 30 Guilford Street, London WC1. (Last of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)

Some Applications of Medical Electronics (6.15 p.m.) Mr D. W. Hill, Institution of Electrical Engineers, at the University College of Swansea, Singleton Park, Swansea.

Studies in Somalia (7.30 p.m.) Dr K. M. Cahill, Royal Society of Tropical Medicine and Hygiene, at Manson House, 26 Portland Place, London W1.

The Design and Function of Static Seals (all-day conference) Institution of Mechanical Engineers, at 1 Birdcage Walk, London SW1.

What is the Significance of Critical Speeds on High Speed Rotating Machines? (6 p.m., discussion) Institution of Mechanical Engineers, Steam Plant Group, at 1 Birdcage Walk, London SW1.

Friday, December 11

Chloride Titanium Dioxide Pigments—Their Value (6.30 p.m.) Oil and Colour Chemists' Association, at the Liverpool Building and Design Centre, Hope Street, Liverpool 1.

Determination of Free Ion-Pair Yields by Pulse Radiolysis (1 p.m.) Dr C. Capellos, Royal Institution, Photochemistry Discussion Group, at 21 Albemarle Street, London W1.

Extra-Galactic Nebulae, Professor J. Heidmann; **Modern Theories of Earth and Planetary Structure,** Professor S. K. Runcorn (4.30 p.m.) Royal Astronomical Society, in the Scientific Societies Lecture Theatre, 23 Savile Row, London W1.

Metamerism, Colour Constancy and Related Problems (6 p.m.) Mr R. Booth, Colour Group (Great Britain), jointly with the Society of Dyers and Colourists, in the Mechanical Engineering Department, Imperial College, London SW7.

The Computer : A Challenge to the Human Brain (9 p.m.) Mr Basil de Ferranti, Royal Institution, at 21 Albemarle Street, London W1.

The Fundamental Reference Frame and the Positions of Faint Objects (2 p.m., discussion meeting) Royal Astronomical Society, at Burlington House, Piccadilly, London W1.

Monday, December 14

Electrical Research on British Rail (7 p.m.) Mr L. L. Alston, Institution of Electrical Engineers, at the College of Further Education, Crewe.

Optical Studies of Adsorbed Layers at Interfaces (two-day symposium) Faraday Society, at the Royal Institution, 21 Albemarle Street, London W1.

Railway Breakdown Services (5.30 p.m.) Mr K. R. M. Cameron, Institution of Mechanical Engineers, Railway Division, at 1 Birdcage Walk, London SW1.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one copy of NATURE each week is:

***12 MONTHS** (52 issues and 4 indexes)

Great Britain and Eire..... **£14 0 0** each

United States of America.....(by air freight)..... **$48** each

Canada.....(by air freight)..... **$52** each

Elsewhere overseas by surface mail..... **£14 0 0** each

(Charge for delivery by air mail on application)

*Shorter periods *pro rata.* (Minimum three months.)

Fear of Enlightenment

THE view that some kinds of knowledge are too dangerous to possess is almost as old as the hills (*Genesis*, Chapter 2, verse 17) and has been suspect for the whole of that time. It is therefore something of a surprise to see that Professor Walter Bodmer and Professor Luigi Cavalli-Sforza argue in the October issue of *Scientific American* that there should be a moratorium on research intended to throw light on questions such as that of whether observed differences between American blacks and whites in IQ scores are genetic in origin. To be sure, Professors Bodmer and Cavalli-Sforza are in quite a different camp from that of the people who persecuted Galileo, for they say that even the process of trying to find out might aggravate racial tensions which already exist in the United States. Specifically, they say:

> In the present racial climate of the United States, studies on racial differences of IQ, however well-intentioned, could easily be misinterpreted as a form of racism and lead to an unnecessary accentuation of racial tensions. Since we believe that, for the present at least, no good case can be made for such studies on either scientific or practical grounds, we do not see any point in particularly encouraging the use of public funds for their support. There are many more useful biological problems for the scientist to attack.

Nobody will doubt the compassion which has impelled the authors to this conclusion, but there are good reasons for asking whether they are right.

The extent to which intelligence is inherited within homogeneous populations such as that of Britain or the white population of North America has in past decades been a similarly tendentious issue. To be sure, the way in which intelligent behaviour has become by natural selection one of the distinctive attributes of the human species implies that there must be at least some genetic components in the determination of individual intelligence. For decades, however, psychologists and their mentors have tended to shy away from attempts at quantitative assessment of the relative importance of genetic inheritance and of environment in the determination of intelligence, chiefly in the belief that studies of this kind would provide ammunition for all kinds of eccentric causes, aberrations like that of the Nazis included. Now, luckily, reticence has to some extent been discarded, with the result that there is a much fuller appreciation not merely of the ways in which intelligence (as measured by IQ) is inherited but also of the extent to which native intelligence cannot be predicted from the intelligence of the parents.

In short, such objective evidence as has now accumulated of the relationship between environmental and genetic determinants of intelligence reinforces and does not diminish the old liberal view that societies of all kinds would lose immeasurably if they did not provide good education for the children of unintelligent parents and also plentiful opportunities for upward social mobility. Nearly a century ago, honest Galton was alarmed at the possibility that a negative correlation between fertility and intelligence might undermine the viability of the human species. There are all kinds of reasons why Galton's fears were exaggerated, but one of the surest safeguards is surely to provide the fullest opportunities for social mobility. In short, the liberals of the thirties might have had the wit to recognize that an objective appreciation of the relationship between genetics and intelligence would have strengthened their case for equal opportunities and not diminished it.

Three decades later, the recognition that the spread of IQ within some social group, however narrowly defined, is likely to be greater than the mean difference of IQ between two groups is not merely a proof that social eugenics based on intelligence is bound to be an illusory business but also an argument for an egalitarian society.

So why not apply the same arguments to the comparison of different races on the grounds of intelligence? This is the first question to ask. The simplest answer is that the question has no meaning (which, fair play, Professors Bodmer and Cavalli-Sforza acknowledge). The genetic isolation between say American blacks and whites has been so complete for so long that nobody can tell whether measurements of IQ developed with some reason as a mark of intelligence within the white community should be taken seriously when applied elsewhere. The second and more interesting answer is that the wrong question has been asked. The outstanding truth about the human species is that half a dozen races have somehow

Pagination of *Nature* plus Two

Contrary to the previous announcement (*Nature*, **228**, 595; 1970), from the beginning of 1971 the pages of the three weekly issues of *Nature* will be numbered independently and not consecutively. A reference to *Nature Physical Science*, for example, would therefore be: Brown, S., and Smith, P. W., *Nature Physical Science*, **229**, 67; 1971. Volumes will continue to be numbered as at present, so that when *Nature Physical Science* and *Nature New Biology* are published on Mondays and Wednesdays next year they will begin at volume 229, which will be the same volume as the Friday issue of *Nature*.

managed to survive the climatic ups and downs of the Pleistocene. As many races and even genera may have disappeared without trace. What, after all, has become of the robust australopithecines (Leakey's *Zinganthropus*)? In circumstances in which it is plain that intelligence has been a crucial asset in survival, it is only reasonable to suppose that all of the races now extant are much of a muchness in intelligence. A demonstration that this is so would surely go a long way to damp down racial tension, as Professors Bodmer and Cavalli-Sforza acknowledge. Should they not have a little more confidence than they display that a proper investigation—including a broadening of the concept of IQ to make this applicable outside the white population for which it was first designed—would produce the result they desire? And is it not also on the cards that qualitative differences in intellectual attitudes should be investigated now, before they are buried forever by the inevitable and desirable miscegenation there is bound to be in the decades ahead?

Another reason for hoping that public funds will not be denied to proposals for making sober comparisons of the intellectual attributes of the several races is that good investigations are essential if ill-judged generalizations on these matters are to be overturned. Second-rate investigations are certain to happen and, as things are, a good deal of rampant race prejudice rests on unfounded assertions (in white communities) that blacks are intellectually less sharp than whites. A moratorium on research will not make these prejudices go away but, rather, will simply ensure that they are never challenged by objective reality. Is this really what Professors Bodmer and Cavalli-Sforza intend? Nobody will dispute the liberality of their motives in suggesting this, but is there not a serious danger that in the complicated circumstances of the modern world, liberalism may take the form of an anxiety not to rock the boat for fear of raising awkward questions? Properly stout-hearted liberalism should take quite a different tack, and should behave as if nothing is ever lost by looking the truth quite squarely in the face. In this case, to be sure, there are all kinds of semantic issues to be settled, not the least of them the definition of suitable yardsticks for the measurement of something as abstract as intelligence. It is also true that there has recently been a great deal of specious argument about the need for studies of the racial genetics of intelligence—Professor W. Shockley has been one of the most infuriating firebrands. None of this, however, amounts to a case for thinking that the whole subject should be put into cold storage. To think that is to play into the hands of the illiberals.

Weathercock Turns Round

THE British Government's decision to contribute towards the 300 GeV accelerator at CERN is at once welcome and distasteful. On balance, it is good for European science and in particular for high-energy physics that there should be a proton accelerator capable of matching to some degree the performance of the machines soon to be commissioned in the United States. The fact that the new accelerator is to be managed by the CERN consortium is also welcome, for the organization has shown itself in the past to be capable and level-headed. At the same time, however, it must be acknowledged that the way in which the 300 GeV project has hung like an albatross round the neck of European physics in the past decade is a sign that the CERN consortium is not nearly as well-knit as it has become conventional to suppose. In the years since 1964, when the project for the 300 GeV machine began to take shape, CERN has blown too noticeably hot and cold. Its first claims on public attention—and on the treasuries of European governments—were far too grandiose and inflexible. In a sense, the organization is lucky that one of its sternest critics, the British Government, is now prepared to foot the bill. It is to be hoped that the organization has learned a lesson from all this.

Complacency has been the most serious of the organization's faults. At the beginning, CERN behaved as if European governments would have to foot whatever bill was presented to them. The first design for the proton accelerator was too cumbersome. CERN nevertheless told potential contributors that there was no room for manoeuvre. If they had paid up and if it had not been for the shining example of Dr R. R. Wilson's bigger but cheaper accelerator at Batavia, Illinois, the chances are that Europe would still be lumbered with a needlessly expensive machine. In the end, only the unwillingness of governments to contribute to this first version of the big accelerator, and their scorn for the plans which accompanied it for building an even larger base of national accelerators on which to erect the 300 GeV pinnacle, persuaded CERN to trim its sails. In the past few days, there has been a great deal of talk of the organization's skill at living within an agreed budget, but this is in sharp contrast with the capacity of the organization to devise plans that are meaningful. The result, unhappily, has been to reinforce the popular but misguided impression that high energy physics is one long extravagance. It is to be hoped that the less ambitious plan to which at least the British Government is prepared to contribute will now help to restore respect for the high energy physicists. Optimism about the 300 GeV machine must naturally be to a large extent counterbalanced by doubts about the future of high energy physics programmes in the countries which contribute to CERN, notably Britain, France and West Germany. It seems to be acknowledged that the British Government will only sign the cheque expected of it if, in the course of the six or seven years during which construction at Geneva will be going on, there is progressive economy in

the cost of the high energy laboratories at Daresbury and Harwell. The larger and more influential groups of high energy physicists will be quite satisfied with this arrangement, no doubt, but less fortunate groups will be harder hit. Yet the British Government and the Science Research Council are entirely right in trying to contain the budget for high energy physics within a substantially constant sum of money. So what is to be done? In circumstances like these, it is surely high time that talk about the international character of high energy physics was lent a greater sense of reality by the setting up of some international machinery for making sure that European resources in this important field are fully pooled. The simplest way of doing this is to provide CERN not merely with the funds for building the new machine but also with responsibility for seeing that machines scattered elsewhere in Europe are made the fullest use of. This would imply that CERN would become a kind of research foundation. It would also imply that individual nations would be offended by what seem to them to be an assault on their sovereignty.

Food for the Crowds
